Biochemical Functions of Nucleic Acids.—*Genetic.*—The universal distribution of the nucleic acids suggests that they must play some essential role in biochemistry. Since DNA is invariably a constituent of the chromosomes and since it is so seldom detected anywhere else in the cell, it seems reasonable to suppose that it may be involved in the mechanism of inheritance (*see also* GENE; GENETICS, HUMAN). The first direct evidence on this question was obtained from studies on bacteria. It has been known for many years that the pneumococci may be classified into a number of strains or types, each characterized by the production of a serologically and chemically specific capsular polysaccharide. The type to which an individual cell belongs appears to be determined by its genetic constitution; the type does not change spontaneously during the life of the cell and at cell division it is passed on to the daughter cells. If, however, a culture of, say, type II pneumococci is treated with an aqueous extract prepared from pneumococci of, say, type III under suitable conditions, some of the cells will lose their capacity to synthesize type II polysaccharide and will acquire the capacity to synthesize type III polysaccharide. By this means pneumococci of any given type may be transformed to any other type by treatment with an aqueous extract of cells of the second type. Such transformed cells show no tendency to revert spontaneously to their original

type, nor do their descendants. It appears, therefore, that transformation involves a change in the genotype of the cells. For this reason transformation has been termed a directed mutation. The active principle of the aqueous extracts that bring about such transformations in pneumococci has been shown to be DNA of high molecular weight. Similar transformations have been demonstrated in a variety of bacterial species, notably *Haemophilus influenzae* and *Escherichia coli*. These alterations have not been limited to changes in cell type or serological character but have included changes in resistance to drugs and capacity to synthesize specific enzymes. In each case the new characteristic acquired by the transformed cell is induced by DNA obtained from a strain of cells of the same species that already possess the characteristic. It would appear, therefore, that the hereditary chemical characteristics of one bacterial cell can be transferred to a second cell of the same species in the form of DNA. This generalization has led to the conclusion that the hereditary characteristics not only of bacterial cells but of cells in general are determined by the DNA they contain; in other words, that DNA is the biologically active material of the gene.

Control of Cell Activities.—Evidence that DNA can profoundly influence the activities of the cell in a specific direction has also been obtained from the study of the DNA-containing viruses, in particular the bacteriophage T2, which infects *E. coli*. Each particle of this virus appears to consist of a DNA core completely surrounded by protein. In the process of infection the particle adheres by means of its protein to the surface of the bacterial cell. The phage DNA then enters the cell, in which it initiates the synthesis of new phage particles. This synthesis is accompanied by rapid and extensive changes in the metabolism of the host cell. The normal synthesis of respiratory and adaptive enzymes, and of RNA, ceases. DNA synthesis continues, but the DNA formed is typical not of the host but of the infecting phage and is characterized by its content of hydroxymethylcytosine, a pyrimidine never found in the DNA of normal *E. coli*. An even more remarkable phenomenon is that a strain of *E. coli* normally incapable of thymine synthesis will begin to produce this pyrimidine as soon as it is infected with phage. All these changes appear to be brought about only by the DNA of the phage. The phage protein appears to take no part in the changes and throughout them remains attached to the exterior of the host cell. If the phage protein is removed from the cell wall after the DNA enters the cell, the production of new phage particles and the concomitant changes in the metabolism of the host continue unaffected. The process of phage infection seems to consist essentially in the transfer of control of the cell from its own DNA to the DNA of the phage. The protein of the phage seems to serve only the quite subsidiary role of protecting the phage DNA and injecting it into the host cell in an active form. A capacity for directing the activities of the cell seems to be characteristic of RNA as well as DNA. Free RNA isolated from tobacco mosaic virus is capable by itself of infecting tobacco plants with mosaic disease and causing the plant cells to support the production of complete virus particles. Here again the protein of the virus seems to serve a completely subsidiary role, perhaps simply as a protective coat to preserve the nucleic acid from inactivation. Similar infective properties have been demonstrated in purified RNA from a wide variety of RNA viruses (*e.g.*, poliomyelitis virus) and in purified DNA from the bacterial DNA virus ϕX 174.

The evidence from viruses therefore indicates that in spite of their chemical differences DNA and RNA are equally capable of assuming control of the activities of the cell. In the normal, uninfected cell, however, this control seems to be vested entirely in DNA.

Certain other characteristics of DNA metabolism seem consistent with this conclusion. In general the amount of DNA per set of chromosomes is remarkably constant for all the cells of any given species, regardless of tissue. This is what one would expect since each set of chromosomes contains the same amount of genetic instructions or information. Again the DNA of the cell, unlike most other cell constituents, is not continually being broken down and replaced. Within the limits of the techniques available, it appears that DNA synthesis takes place only in preparation for chromosome reduplication (*e.g.*, at mitosis) and that once DNA is synthesized it does not break down during the life of the cell.

Structural Basis of Control and Duplication.—At first sight DNA might seem an unlikely candidate for the role of controlling the activities of the cell since it is built up from only four different kinds of deoxynucleotide unit and since these are always linked together in the same way to give a long unbranched polynucleotide chain. Clearly one such chain can differ from another only in the number of each type of nucleotide it contains and in the sequence in which the nucleotides are arranged. It follows therefore that whatever instructions the DNA molecule may contain about the activities and capacities of the cell must be recorded in some sort of "code" expressed in the sequence of bases along its length. Moreover, by definition this set of instructions must be duplicated precisely and completely every time a cell divides in order that the daughter cells may inherit the characteristics of the parent. In other terms, there must be some mechanism by which the order of bases in an existing DNA chain is exactly copied in a new DNA chain.

The probable mechanism by which this is brought about was elucidated from a study of the structure of the DNA molecule. On the basis of nucleotide composition, physical properties and, in particular, X-ray crystallography (M. H. F. Wilkins), the DNA molecule is believed to consist of two deoxypolynucleotide chains running parallel to one another but in opposite directions. The bases in each chain are so arranged that an adenine in one chain is always opposite a thymine in the other and vice versa; and a guanine in one chain is always opposite a cytosine in the other and vice versa (*see* fig. 5). The two chains are held together by hydrogen bonding between these base pairs. The chains are not straight but are twisted into a regular double helix (*see* fig. 6) and the pairs of bases lie at right angles to the helix, like the steps of a spiral staircase (J. D. Watson and F. H. C. Crick).

Duplication.—A molecule of this sort, in which each strand is the exact complement of the other, could be duplicated in the manner shown in fig. 7. For convenience only a very short length of the molecule is shown and the representation is purely diagrammatic; nucleotides are indicated by their initial letters. It is necessary to suppose as a first step that the relatively weak hydrogen bonds linking the two strands can be broken and that somehow the strands can be separated (fig. 7[b]). In the second step (fig. 7[c]) each base in either strand must be supposed to bind to itself the complementary free deoxymononucleotide by the same pattern of hydrogen bonds that existed in the original intact molecule. The third step would be the polymerization of these attached deoxymononucleotides to give two new polynucleotide strands, each strand exactly complementary to the old one on which it was formed (fig. 7[d]). The result of the entire process is that the original DNA molecule is replaced by two molecules, both identical with their progenitor and both containing one strand derived from it and one strand newly synthesized (*see* fig. 7[a and d]).

The actual process of DNA formation can be demonstrated in the test tube using an enzyme prepared from microorganisms or from animal tissues. The deoxymononucleotides to be converted into DNA must be in the form of the nucleoside triphosphates instead of the monophosphates and the reaction can be represented as follows (Arthur Kornberg):

$$\text{nucleoside triphosphates} \rightarrow \text{DNA} + \text{inorganic pyrophosphate}$$

Since the synthesis in vitro will take place only in the presence of an existing DNA molecule acting as primer, and since the synthetic DNA formed in the reaction has a nucleotide composition similar to that of the primer, it seems reasonable to conclude that the latter is acting as a template for the synthesis in the manner postulated above. Moreover, DNA in which the double helix arrangement has been broken up by heating in solution to a temperature sufficient to rupture the hydrogen bonds seems to be particularly effective as a primer.

In vivo also, DNA synthesis seems to follow the sort of mecha-

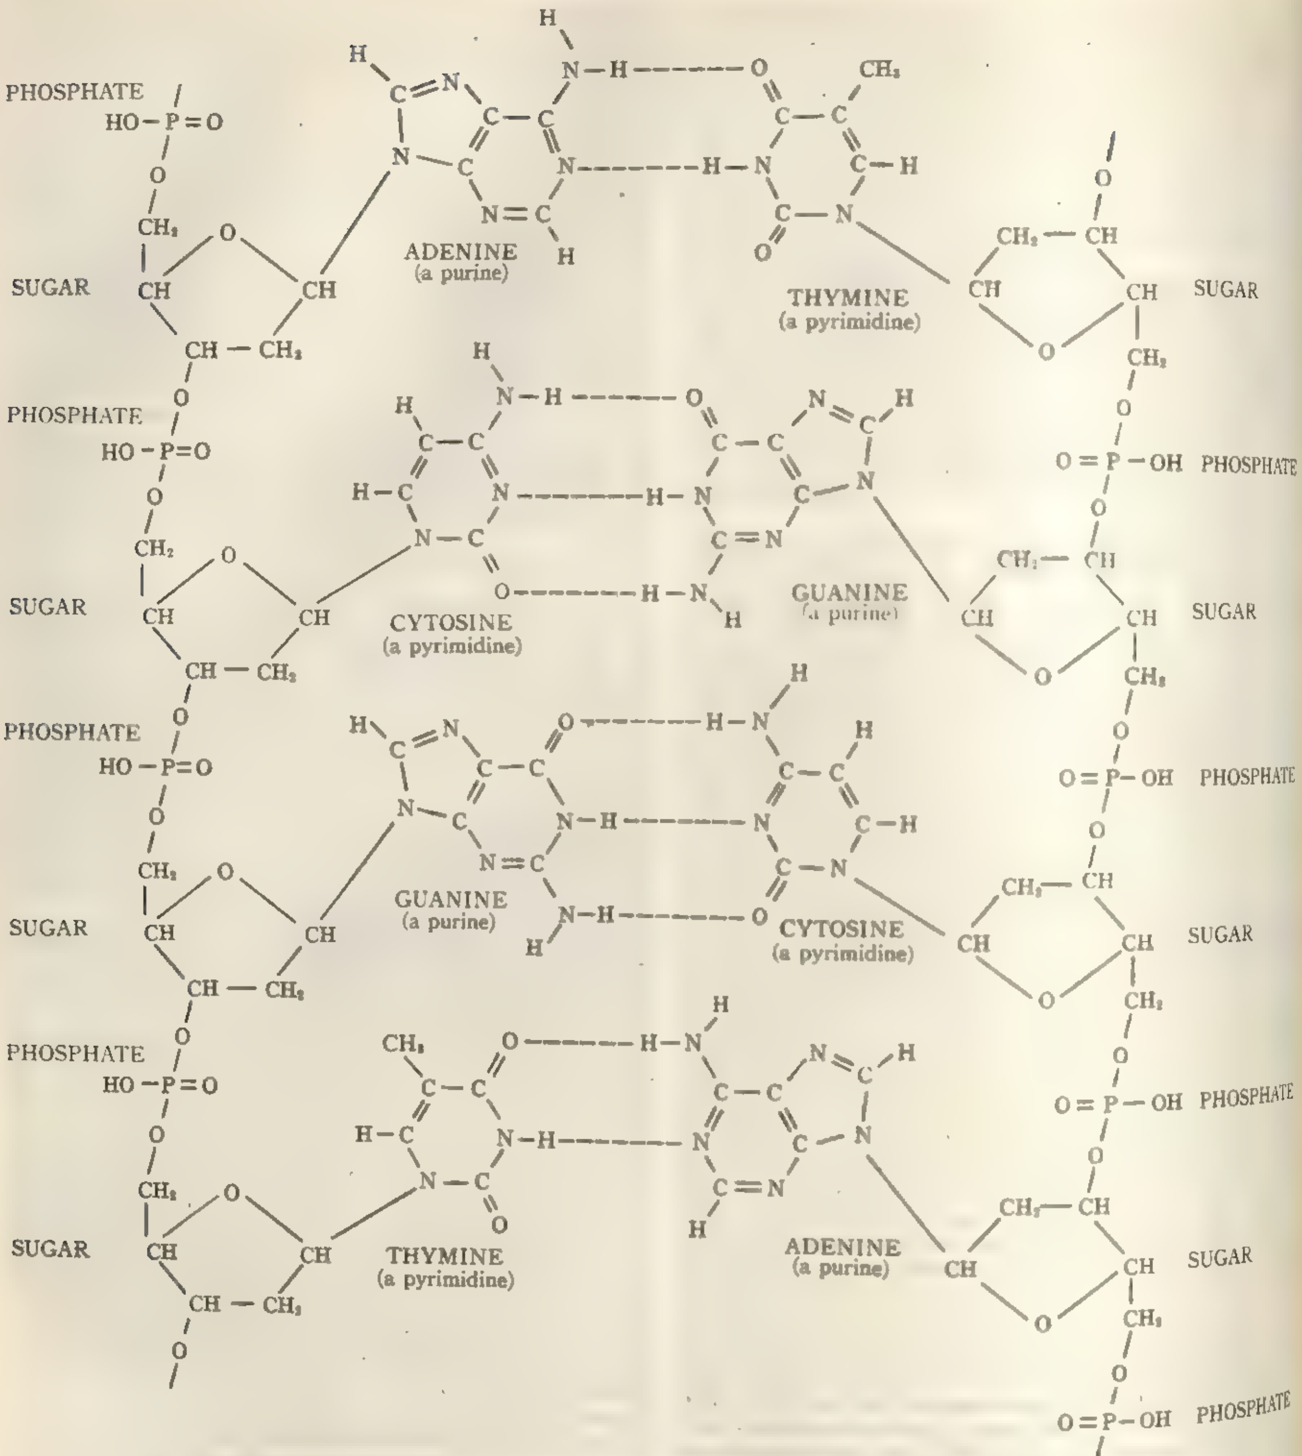

FIG. 5.—DIAGRAM OF SECTION OF DNA MOLECULE SHOWING PAIRING OF BASES ON PARALLEL POLYNUCLEOTIDE CHAINS

nism described above, since it can be shown by isotope methods that when new DNA molecules are formed they consist of two subunits, one derived from an existing DNA molecule and the other newly synthesized.

Determination of Protein.—The biological role postulated for DNA implies not only that it must be capable of exact reproduction but also that it must have an effective mechanism for determining the activities of the cell. Studies of the biochemistry of genetics have indicated that in the first instance this control is probably achieved by determining the nature of the proteins, particularly the enzymes, that the cell can synthesize. Proteins are exceedingly complex in structure. Not only are they built up from an average of 200 units of at least 20 different types of amino acid but the polypeptide chains in which these are arranged are twisted into precise and elaborate geometrical arrangements.

As a first approximation, however, it seems reasonable to suppose that the most important feature of protein structure is the number of different types of amino acid in the polypeptide chain and the order in which they are arranged (*see* PROTEINS: *Structure of Protein*). The fact that this arrangement is under detailed genetic control has been strikingly demonstrated by the study of the occurrence of certain abnormal hemoglobins in man. The ability to synthesize these is genetically determined in accordance with the classical Mendelian principles, yet by chemical analysis it has been shown that the abnormal hemoglobins may differ from normal hemoglobin in only one of the approximately 300 amino acids of the molecule. Presumably, therefore, the sequence of amino acids in the polypeptide chain of a protein synthesized by a cell depends ultimately on the sequence of nucleotides in the DNA of one of the cell's chromosomes.

A crude and admittedly tentative picture of how the sequence of amino acids is determined can be put forward. Since about 1940 it has been known that cells that synthesize a great deal of protein either for their own growth (*e.g.*, in embryonic tissues) or for secretion (*e.g.*, in the pancreas) have a high content of RNA. The tissue fractionation technique described above has shown that most of the RNA is in the ribosomes but that some of the remainder, the sRNA, is in solution in the cell sap. This sRNA has the remarkably low molecular weight of about 25,000, which is equivalent to about 80 nucleotides. These are apparently arranged in a single chain looped back on itself to give a short two-stranded structure. Under appropriate conditions an amino acid molecule can be attached to the ribose of the last nucleotide of the chain. The amino acid is first activated so that it forms its acyl anhydride in combination with the mononucleotide adenosine monophosphate thus:

amino acid + adenosine triphosphate
$\rightarrow$ amino acyl adenosine monophosphate + inorganic pyrophosphate

The adenosine monophosphate is then replaced by sRNA:

amino acyl adenosine monophosphate + sRNA
$\rightarrow$ amino acyl sRNA + adenosine monophosphate

These reactions are catalyzed by the same enzyme. There appears to be a separate activating enzyme and a separate species of RNA for each of the 20 amino acids involved in protein synthesis. The sRNA molecules, each with its attached amino acid, are then taken up by the ribosomes and it is there that the actual process of protein synthesis takes place. It is thought that the amino acids are aligned in the correct order because of some correspondence between the small sRNA molecules (transfer RNA) to which they are attached and the RNA (messenger RNA) of the much larger ribosome particle. Possibly the individual sRNA molecules may be complementary in their sequence of bases to particular sites in the ribosomal RNA and may be capable of specific combination with these sites, perhaps by the same sort of hydrogen bonding as holds the two strands of the DNA molecule together.

A mechanism of this sort implies that the type of protein synthesized depends on the nature of the RNA of the ribosomes; *i.e.*, on its base sequence. It follows, therefore, that the control of protein synthesis by DNA must be exerted by the DNA determining the base sequence in at least part of the ribosome. There is evidence that this may be brought about by the so-called messenger RNA. This is a relatively small fraction of the RNA of the cell that is rapidly synthesized and equally rapidly destroyed.

In the synthesis of RNA, DNA (in single stranded form) is thought to act as primer and the mechanism of synthesis is believed to be analogous to that of DNA so that the nucleotide sequence of the newly synthesized RNA corresponds to that of the DNA primer. Using purified enzymes it can be shown in the test tube that RNA synthesis can be "primed" by DNA and that the product of the synthesis has a nucleotide composition corresponding to that of the DNA primer (the uracil of the RNA being taken as equivalent to the thymine of the DNA). Again there is evidence that when a bacterial cell is infected by a DNA virus one of the first consequences is the synthesis of a new messenger RNA corresponding in base composition to the DNA of the virus and that this new messenger RNA is taken up by the ribosomes and it determines the nature of the proteins that are to be synthesized. It seems reasonable to assume that in the normal cell the DNA controls protein synthesis by a similar sort of mechanism.

FIG. 6.—DIAGRAM INDICATING DOUBLE HELICAL STRUCTURE OF NUCLEIC ACIDS

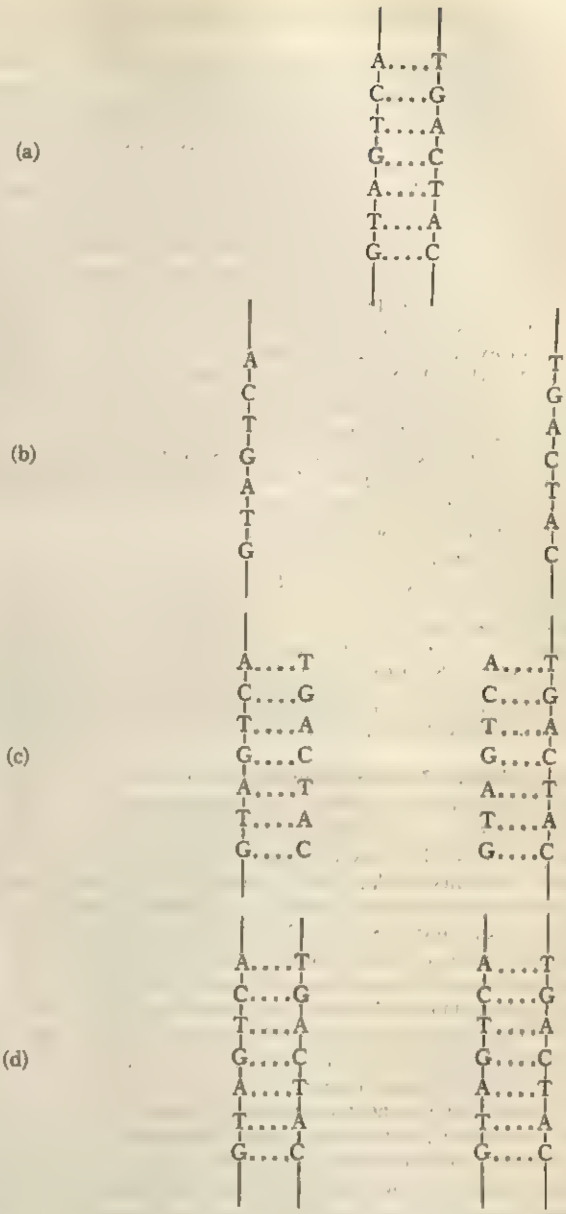

FIG. 7.—SKETCH SHOWING POSSIBLE DUPLICATION METHOD

Proteins and the Genetic Code.—If protein synthesis is accomplished by a mechanism of this sort, there must be some sort of relationship between the sequence of bases in the DNA (and messenger RNA) and the sequence of amino acids in the protein produced. Since DNA and RNA are built up from only four different types of nucleotide whereas proteins are built up from about 20 different types of amino acid, it follows that each amino acid in the protein chain must be represented in the nucleic acid chain not by a single nucleotide but by a group of nucleotides. The nature of this code by which amino acids are represented is still the subject of speculation. It seems likely, however, that if each amino acid is represented by a specific group of nucleotides

there must be three nucleotides or a small multiple of three in each such group.

Some information about the code has been obtained by making use of synthetic polynucleotides (Severo Ochoa) as messenger RNA. Such synthetic polynucleotides can be added in the test tube to a system containing ribosomes, sRNA and the enzymes and cofactors necessary for protein synthesis. By comparing the composition of the synthetic polynucleotides with the relative proportions of the different amino acids taken up by the ribosomes it is possible to deduce a tentative relationship between the nucleotides of the messenger RNA and the protein synthesized. For example, if a synthetic polynucleotide consisting solely of uridine nucleotides is tested in this way it is found that the ribosomes take up an exceptionally large amount of the amino acid phenylalanine (Marshall W. Nirenberg and J. Heinrich Matthaei). From this it is concluded that phenylalanine must be represented in the code by a group of uridine nucleotides (presumably three). By similar arguments groups of nucleotides have been provisionally assigned to all 20 amino acids. These details were speculative and controversial in the early 1960s but the general correctness of the scheme seemed to be well established.

NUCLEUS. In animals and higher plants a nucleus is that portion of the cell containing the hereditary materials (chromosomes, genes) and a nucleolus. It is discussed in the article Cell. This article deals with the nucleus of the atom, a particle of very small radius and exceedingly great density located at the centre of the atom. All but a negligible fraction of the atomic mass is concentrated in the nucleus. At the same time the size of the nucleus is more than 100,000 times smaller than the size of the atom. The approximate size of the atom, in turn, is a few 1,000,000,000ths of an inch (*i.e.*, one, two or three times 10^{-8} cm.). The nucleus carries a positive electric charge that is an integral multiple of the elementary charge (whose magnitude is 4.8×10^{-10} electrostatic units).

By the mid-1960s understanding of the nature of atomic nuclei had reached the point where radical changes were being felt in the personal, social, economic and political lives of people throughout the world. In medicine, diagnostic and therapeutic methods employing particles derived from atomic nuclei increasingly were being used; improved new varieties of food plants and animals were being produced with nuclear techniques (*see* Radiation: Biological Effects).

Ancient aims of alchemy (*q.v.*) to achieve transmutation of chemical elements finally were being realized as methods for manipulating the constituents of atomic nuclei developed. Enormous energies that bind these constituents together were being released to revolutionize methods of warfare, and were being controlled to fuel ships and illuminate cities. The dominance of any nation in international politics was beginning to hinge on the skill of its scientists and technicians in dealing with the atomic nucleus. The discussion that follows summarizes the principles and discoveries of nuclear physics that underlie these world-wide changes.

The discussion of the atomic nucleus to follow is organized as follows:

I. Description and History
II. Detection of Nuclear Processes
III. Constituents of the Nucleus
IV. Nuclear Energy
V. Further Properties of Nuclei
VI. Beta Decay
VII. Alpha Decay and Spontaneous Fission
VIII. Metastable Nuclei
IX. Nuclear Reactions
X. Summary of Nuclear Properties
XI. Nuclear Structure and Nuclear Forces
XII. Energy Production in Stars
XIII. Utilization of Nuclear Energy
XIV. High-Energy Experiments on Nuclei

I. DESCRIPTION AND HISTORY

The first clear evidence about the internal structure of the atom was obtained by E. Rutherford in 1911. He was led by his experiments to assume that atoms consist of a nucleus, as described above, and a number of electrons. These electrons carry a negative elementary charge (of magnitude 4.8×10^{-10} electrostatic units) and they have a mass which is a small fraction of the atomic mass. (The fraction representing the total weight of the electrons in the atom to the atomic weight is $\frac{1}{1,840}$ in the case of hydrogen, the lightest element, or $\frac{1}{4,700}$ for uranium, a typical heavy element.) The number of electrons in the atom is equal to the number of positive charges the nucleus carries so that the atom as a whole is neutral. The atomic number and the designation Z are used for either of these quantities. All chemical and most physical properties of atoms are determined, apart from exceedingly small variations, by the atomic number Z. Atoms having a given Z value form an atomic species. For example, if the nucleus has one unit of charge and one electron is present we have a hydrogen atom. As further examples, nuclei with 2, 6, 26, 79 and 92 charges may be mentioned; the corresponding atoms have 2, 6, 26, 79 and 92 electrons and the atomic species are helium, carbon, iron, gold and uranium, respectively. The chemical transformations, the appearance and common behaviour of materials built from the atoms depend only on the configuration of the electrons. This is influenced, in turn, only by the nuclear charge and is practically independent of other properties of the nucleus. The atomic properties are discussed in detail in Atom. In the following the interest is in the central particle; *i.e.*, the nucleus.

Formerly it was believed that atoms were immutable entities. This statement did not imply that the configuration of the electrons in the atoms could not change. It was, indeed, soon recognized that chemical changes are caused by the rearrangement of the electrons. As long as the charge of the nucleus has remained the same, however, the atom is considered unchanged. No matter what deformation occurs in the electron arrangement, it will always return to the normal configuration as soon as the disturbing force is removed.

In 1896 A. H. Becquerel noticed that uranium emits unusual radiations, designated as radioactivity. In the next few years the work of Marie and Pierre Curie, E. Rutherford, F. Soddy and others led to the recognition that the phenomenon had to be explained by a spontaneous, permanent and intrinsic change of the atomic species (*see* Radioactivity). In uranium this is brought about by the emission of a particle from the nucleus which carries away two units of positive charge and which is called an α-particle (alpha particle). Thus the uranium nucleus, originally containing 92 units of charge, disintegrates into a nucleus containing 90 units of charge. This nuclear charge characterizes a different atomic species, thorium. These phenomena will be discussed later in the section on α-decay. The emitted particle has a very high velocity, as much as the 20th part of the greatest possible velocity, that of light. Thus a much larger kinetic energy is concentrated on the α-particle than was ever before found on a body of comparable mass. Actually the α-particle is the nucleus of the helium atom (*see* Alpha Particles).

In the hands of Rutherford these α-particles became powerful tools in exploring the interior of the atoms. In experiments published in 1911 Rutherford showed that the majority of particles pass through thin (of the order of $\frac{1}{10,000}$ in.) but solid foils without being deflected. A few α-particles were scattered through quite large angles. These observations could be explained by assuming that the α-particles had collided with heavy, charged particles, the atomic nuclei. The greater number of small deviations were the result of distant collisions; *i.e.*, of forces acting between two particles which did not approach closely. The large deflections were caused by the larger force of two charged particles more nearly in contact. In order to account for the large number

of undeviated particles, the nucleus had to be given a radius small compared with that of the atom. Rutherford assumed that the charge of the nucleus is positive and that the remainder of the atom consists of the light negatively charged electrons.

Collisions between the α-particles and the electrons are much more frequent than the noticeable collisions between α-particles and nuclei, but because of the small mass of the electron these collisions do not result in an observable deflection of the α-particles. Rather they cause a gradual loss of energy of the α-particles. The distance through which the particle travels before it loses all of its available energy is called the range of the particle. The range depends, in general, on the initial energy of the particle, on its charge, its mass and on the density of the electrons with which it can collide. The hypotheses which Rutherford made to explain his experiments have been fully verified by the experimental and theoretical studies of atomic and nuclear physics.

In 1919 Rutherford observed that nitrogen bombarded by α-particles emitted a new product. This turned out to be a nucleus of the hydrogen atom, which is called a proton, carries a single unit of positive charge and is the simplest of all atomic nuclei. The reaction was produced by a close collision of the α-particle and the nucleus of the nitrogen atom, which carries seven positive charge units. The α-particle attached itself to the nitrogen nucleus, producing a so-called compound nucleus of high internal energy. From this structure the fast proton is subsequently emitted. The actual time for the emission is an exceedingly small fraction of a second (*see* PROTON).

The result of this nuclear reaction is that the nitrogen nucleus, having absorbed the α-particle with two positive charges and having emitted a proton carrying only one positive charge, has now turned into an oxygen nucleus. In this way Rutherford's experiments accomplished the transmutation of nitrogen atoms into oxygen atoms. At the same time the bombarding helium nuclei were transformed into hydrogen nuclei. In the process the kinetic energy of the system had also changed. The final particles contained less energy than the original helium nuclei.

Rutherford's experiments also explained why the transmutation of elements could not be accomplished by the previously used methods of chemistry and physics. Artificial change of nuclear charge requires a nuclear reaction induced by the close contact of two atomic nuclei. Because of the strong electrostatic repulsion of the positively charged nuclei, sufficiently close contacts can occur only if the nuclei approach each other with a high initial velocity. The required high velocities do not occur in chemical processes and thus the endeavour of the alchemists to transmute elements by chemical means was doomed to failure. As soon as methods and techniques specialized in the production and observation of high-velocity particles were developed, transmutation of atoms could be observed.

The study of atomic nuclei remained a field sharply separated from the investigation of atoms and from other branches of chemistry and physics. The reason for this is twofold. First, the details of nuclear structure influence the properties of the atom as a whole and the properties of matter in bulk to an exceedingly small extent.

Thus the study of the structure of matter could proceed without detailed knowledge of the atomic nucleus. Second, the internal behaviour of nuclei can be influenced only when energy is present in very high concentrations. The required high energies are carried by α-particles such as were used in Rutherford's experiments. In chemical and most physical processes, however, the concentration of energy is not high enough to influence the behaviour of nuclei to a noticeable extent. Thus, nuclear processes occur, so to speak, in a world of their own and unusual special methods must be devised to penetrate into this world.

For several years following the publication of these first experiments on nuclear transmutations, radioactive materials occurring in nature remained the only source of high-energy particles. The study of nuclear processes was handicapped by the relatively small number of particles these sources made available to the experimenter. Observations had to be made over quite long periods of time and results had to be based on the observations of relatively few processes. Nuclear scientists therefore made every effort to produce similarly fast particles by artificial means. The first machine to do this was the cascade transformer of C. C. Lauritsen, H. Crane and others which was completed in 1928. This was followed by the machine of J. D. Cockcroft and E. T. S. Walton in 1929 and the electrostatic generator of R. J. Van de Graaff in 1931. These machines are called linear accelerators, a term derived from their common fundamental principle. The charged particles, such as protons or α-particles, are introduced at one end of a cylinder containing a very strong and extended electric field. As the particles move through the field they are continuously accelerated. In order that no energy should be lost by collisions with atoms, the cylinder is evacuated. The fundamental principle of these machines is the method by which the necessary electric fields are obtained.

Another principle was used in the cyclotron (E. O. Lawrence, 1932, *see* ACCELERATORS, PARTICLE). In this machine particles are confined by a magnetic field to a spiral-shaped orbit and accelerating electric fields are repeatedly applied while the particles are moving along this orbit.

The betatron (D. W. Kerst, 1940) is similar to the cyclotron in that the particles are confined by a variable magnetic field. The acceleration, however, is accomplished by the principle of induction. According to this principle, increase of current in one coil induces an opposite current in a coaxial coil. In the betatron a change of current in a coil causes an acceleration of electrons which do not move in a second coil but rather in free space. An important practical difference between the cyclotron and the betatron is that the former is used to accelerate atomic nuclei while the latter accelerates electrons.

After 1945 improvements in all these machines became possible through closer control of the electromagnetic fields which are used to confine and accelerate the particles. In some of these, electrons or nuclei are accelerated in straight lines (L. W. Alvarez, acceleration of protons, 1946; H. H. Hansen, acceleration of electrons, 1948). Acceleration is achieved by the continuous action of an accelerating field which moves along with the accelerated particle. A machine of the cyclotron type is the synchrotron (E. M. McMillan and V. I. Veksler, 1945) for the acceleration of electrons. In this machine electrons are kept in a circular orbit by a changing magnetic field and the acceleration is accomplished by repeated application of an electric field near a certain point in the orbit of the electrons. By a close correlation between the changing magnetic field and the period in which repeated accelerations are applied (synchrocyclotron), it became possible to accelerate nuclei to very high energies; the highest energy reached in the early 1960s was in the proton accelerator at Brookhaven National laboratory, Upton, N.Y. The energy obtained was approximately 8,000 times higher than the energy of the α-particles of uranium.

These high-voltage machines were capable of producing a considerable number of nuclear reactions which were, in principle, analogous to the reaction studied by Rutherford in 1919. In some of these reactions energy was released, in others energy was absorbed, but in all cases the energy changes were great compared with the energy changes involved in chemical reactions.

In 1932 Irène Curie and F. Joliot discovered that by nuclear reactions radioactive nuclei can be produced. In their experiments they used, like Rutherford, α-particles. With these they bombarded boron atoms, whose nuclei carry five elementary charges. The resultant nucleus contained two more charges and was therefore a sevenfold charged nucleus, or a nitrogen nucleus. This nitrogen nucleus differed from all nitrogen nuclei found in nature in that it emitted a particle called the positron. This particle is similar in all respects to the electron discussed above except that it carries a positive rather than a negative charge. In the following years a great number of radioactive nuclei were produced. Many of these emit positive electrons like the nitrogen nucleus just described, others emit the more common negative electrons. Radioactivities of this type are called β-activities, and the positive or negative particles emitted by the nuclei are called β-rays. (*See* RADIOACTIVITY.) Actually β-radioactivity was discovered practically simultaneously with α-activity, but up to 1932 only

a few naturally occurring β-activities were known. All elements can be obtained in a radioactive form.

Considering the great energy release which was frequently encountered in nuclear reactions, the question arose whether it would be possible to utilize this energy. This was not possible for the following reason: in order to release nuclear energy one had to start with highly energetic particles. Most of these particles, if they impinge on a piece of matter, will not get close to nuclei and will not produce reactions but will instead squander their energy by making collisions with light electrons. In this way the originally concentrated energy of the particles will ultimately be transformed into heat. Only a small fraction, less than $\frac{1}{100}$ of 1%, of the originally fast particles get close enough to an atomic nucleus to produce a nuclear reaction. In these rare instances the nuclear energy may be greater, sometimes even 10 or 100 times greater, than the energy of the impinging particle but since these processes occur only rarely, the net gain in energy is small. The bombardment of a piece of material by a stream of energetic, charged particles will thus produce a heating of the bombarded sample which is only slightly increased by the reactions occurring in the sample. Considering the exceedingly high cost of the original source of energy, the actual slight energy production could not be considered as a practical source of power.

A great number of additional nuclear transformations became possible in 1932 when J. Chadwick discovered the neutron (*q.v.*). This particle has a mass which is very slightly in excess of the mass of the hydrogen nucleus, or proton. In contrast to the proton, however, it carries no charge and is the only known nuclear particle that is neutral. Consequently the neutron does not attract any electrons and does not have the property of other nuclei of surrounding itself with an extended electron configuration. Thus one of the striking properties of the neutron is that it may penetrate almost freely through several inches of solid materials, being influenced in its path only whenever it touches an atomic nucleus.

The fact that neutrons are not charged gives rise to a second important consequence. This is that neutrons can approach any nucleus without being repelled by the charge on the nucleus. Therefore a neutron need not have a high velocity, or a high energy, in order to cause a nuclear reaction. Unlike the charged particles the neutrons can approach with equal ease such nuclei of small charge as those of nitrogen or such nuclei of high charge as those of gold or uranium. This fact was utilized by many investigators following 1932 to explore a great number of nuclear reactions. E. Fermi and his collaborators in Rome, Italy, were by far the most active and successful workers in the field.

The fact that a neutron need not have high energy for it to approach a nucleus reopens the question of whether nuclear reactions can be used to produce useful power. Unfortunately neutrons could be produced only in reactions in which fast particles were involved. A typical example is the reaction described above in which a fast α-particle impinges on a boron nucleus and forms a radioactive nitrogen nucleus. In this reaction a neutron is also ejected. In the final analysis this neutron represents as costly an investment of energy as the fast particle itself and practical power production by this means seems to remain unattainable.

Actual utilization of nuclear energy on a large scale became a concrete possibility at the end of 1938 when O. Hahn and F. Strassmann in Berlin, Ger., discovered uranium fission. These investigators made a careful study of the artificial radioactive substances that were obtained when neutrons impinged on the uranium nucleus. Fermi and his collaborators had noticed several years earlier that when a uranium nucleus is hit by a neutron, a variety of radioactive substances are produced. At that time the reaction was not understood. Hahn and Strassmann specifically identified barium in the bombarded uranium target they were studying. To explain the presence of this much lighter element a very violent reaction must have occurred in the uranium nucleus. It was concluded that the nucleus of uranium, because of its large size and the repulsion of its many positive charges, is on the verge of disintegration. The additional energy brought into the nucleus by the neutron is sufficient to make the nucleus break apart. The process is called the fission of the nucleus. The electrostatic repulsion of the product nuclei at the instant of fission makes them fly apart with great velocity and an amount of energy unusually large even in the scale of nuclear energies. This splitting of the uranium nucleus can occur in a number of ways, giving a variety of pairs of disintegration products. These nuclei, which are unstable and disintegrate by β-particle emission, add to the energy liberated by the reaction. The above conclusion was reached and verified experimentally by several scientists. The first of these were O. Frisch and L. Meitner in Copenhagen, Den.

It was further guessed that neutrons are liberated in fission making possible a chain reaction. If, for instance, 2 neutrons were emitted, these could react with uranium nuclei producing 4 neutrons. These would multiply to 8, then to 16 and so on. In a few steps the number of neutrons will become extremely large, the reaction is accelerated and energy is liberated at an ultimately explosive rate. Later in 1939 L. Szilard, F. Joliot and others experimentally verified the liberation of a sufficient number of neutrons. This was the necessary proof of the feasibility of a chain reaction and work was begun on producing such a reaction. To control the chain reaction means, first, to allow neutrons to multiply and, subsequently, to strike a balance of neutron production and neutron absorption so that the number of neutrons just maintains itself and does not grow to explosive proportions. This was first achieved under the guidance of E. Fermi on Dec. 2, 1942, at The University of Chicago. Subsequently, many additional nuclear reactors were built, all based on the principle explained above. Some of these reactors liberate considerable amounts of energy and progress has been made toward transforming this energy into useful power.

In 1942 the development of the explosive aspects of the nuclear chain reaction was undertaken by a group headed by J. R. Oppenheimer. On July 16, 1945, the first so-called atomic bomb was exploded in the desert near Alamogordo, N.M. Afterward, two atomic bombs were exploded over Japan. In the following years numerous tests of atomic bombs were carried out by U.S. scientists in the Pacific and Nevada, by Soviet workers; and by a British group in Australia. In later tests (in particular the U.S.S.R. test of 1953 and the U.S. tests of 1951 and 1952), the explosion was based in part on the building up of light nuclei. The nuclear reaction involved in that case is the fusion of small nuclei into larger units rather than the fission of the heaviest nuclei into two parts. The fusion reaction is most easy if hydrogen nuclei are involved which carry only a single unit of charge and if the temperature in the reaction is extremely high so that charged particles can approach each other. The designations hydrogen bomb and thermonuclear bomb refer to the facts just mentioned. *See* ATOMIC ENERGY.

II. DETECTION OF NUCLEAR PROCESSES

When a nuclear reactor produces energy, and particularly when an atomic bomb explodes, the effects of nuclear processes are very noticeable, even without elaborate detecting devices. The energy released appears in the form of heat or, in the case of the atomic bomb, partly in the form of motion of air masses, light and other radiations. Some of these radiations are capable of ionizing and rearranging individual molecules. If that happens extensively in living tissue, radioactive burns result and the tissue may suffer serious damage (*see* RADIATION: BIOLOGICAL EFFECTS).

In the development of nuclear science, both past and future observations of an individual process are more important than the observation of the impressive phenomena that accompany the large-scale release of nuclear energy. Individual nuclear processes are observable, in fact, for two reasons. One is that particles participating in nuclear reactions as a rule have exceptionally high energy and are, for that reason alone, noticeable among the myriads of atoms of comparable size but much lower energy through which these nuclear fragments move. Another reason is that the effects of these fast particles can be amplified. Thus they can easily be detected by the use of suitable apparatus (*see* NUCLEAR INSTRUMENTS).

Any of the charged particles or electromagnetic radiations connected with nuclear reactions can produce an effect in a photographic plate similar to that of light. This effect essentially consists of producing disturbed grains in the photographic plate. These disturbed grains then are developed in subsequent chemical processes so that a deposition of metal big enough to be visible to the naked eye or under the microscope is formed at the position of the disturbed grain. The process of developing plays in this special instance the role of amplifying the original effect of the nuclear radiation. The characteristic property of nuclear fragments is their high energy by which they can activate a number of grains lying along a straight line. Use of photographic plates of various sensitivities and detailed study of the density of the excited grain and of the length of the track make it possible to recognize the kind and energy of the particles that cause the track. It is interesting to note that the blackening of a photographic plate by the faintly radioactive pitchblende started A. H. Becquerel in 1896 on the first investigation of a nuclear process. Half a century later the finer methods of observation described above made photographic plates most valuable tools of research in nuclear physics.

The Wilson cloud chamber, devised by C. T. R. Wilson in 1912, is a piece of apparatus especially designed for the detection of charged nuclear fragments (*see* CLOUD CHAMBERS). In its general principle of action it is similar to the photographic plate. In the latter nuclear radiations give rise to disturbed centres in the photographic emulsion. In the cloud chamber, α-rays or other fast charged particles form ions (*i.e.*, charged atoms or molecules) along their paths. The process of developing is replaced in the cloud chamber by a process of condensation. The cloud chamber contains a vapour, usually water vapour, which is maintained at a temperature just above the condensation temperature. Following the passage of nuclear particles, the cloud chamber is expanded and by this process the vapour contained in it is cooled so that condensation sets in. The water molecules are attracted to the ions which mark the trail of the fast particle. Thus a set of droplets is formed making the path of the particle visible. The process of amplification in this case is the growth of the droplets around the ions.

There is one method of observing nuclear particles without the use of an amplifying mechanism. This is the method of observing fluorescence or scintillations. Along the path of the fast particles atoms and molecules are not only ionized but also disturbed to various degrees. These atoms and molecules return to their normal states and in doing so emit light. The light effects produced in a suitable fluorescing material by a single α-particle are actually visible to the naked eye. These individual processes are called scintillations. It is remarkable that in a scintillation the effects of a single nuclear process can be seen directly without the use of intervening equipment. This is possible because of the great amount of energy of the α-particle and the extremely great sensitivity of the human eye. As a practical means of studying nuclear reactions the observations of scintillations were of great importance about 1920. The scintillation method, combined with sensitive apparatus for the detection and amplification of light, again proved of great usefulness.

Electrical apparatus may also be used to detect nuclear particles. In these detecting devices the ions produced by the nuclear particles are set in motion by electric fields. This can be done in a variety of ways. The field may be chosen relatively small and its effect may be merely to collect the ions on an electrode. In this case the resulting current is always so small that in order to observe it one has to amplify the current. This is done by equipment similar to the common radio receiving sets. If stronger fields are used to move the original ions, these ions may acquire enough energy to knock electrons out of other atoms or molecules, thereby producing more ions. In this way some amplification takes place immediately. This initial amplification might become so considerable as to develop into an actual discharge, as happens in the Geiger-Müller counter.

Electric detecting devices are particularly useful because of their great flexibility. They can be set in a way to become selectively sensitive to a specific particle. When arranged and coupled in an appropriate manner these electric devices can count particles of a specified energy. They can be used to study the coincidence in time of two processes. Therefore they can furnish the important information that two nuclear particles have been released in the same process. Finally, by automatic recording the number of various kinds of particles that have passed through a counter may be found.

While electric fields are most frequently used in collecting the ionized atoms along the path of a nuclear fragment, magnetic fields are frequently used to determine the exact speed and energy of the fragments. Simultaneous use of electric and magnetic fields gives important information to indicate the mass of the particle under study. This latter piece of equipment, the mass spectrograph, is not, properly speaking, an instrument of detection, but a precision instrument designed to measure one of the basic properties of nuclei (*see* MASS SPECTROSCOPY).

Among the nuclear fragments there is one which cannot be observed directly by any of the methods described above. This particle is the neutron. The detection of neutrons proceeds as a rule in an indirect way. The collisions of the neutron with atomic nuclei of various kinds produce fast, charged particles or electromagnetic radiation and either of these may be detected by one of the many methods that have been described.

III. CONSTITUENTS OF THE NUCLEUS

According to ideas in the 1960s the nuclei are built from two simpler particles, the neutrons and the protons. These two particles, which are considered the building blocks of nuclei, are also called nucleons. As has been mentioned above the protons carry the elementary charge (4.8×10^{-10} electrostatic units), whereas the neutrons do not carry a charge. Physicists introduce a special atomic mass unit (amu) that has $\frac{1}{12}$ the mass of carbon-12; 1 amu $= 1.6604 \times 10^{-24}$ g. Atomic weight tables based on carbon-12 show the following weights in amu: hydrogen 1.00797, the proton 1.00728, and the neutron 1.00867. These values can be expressed in grams if multiplied by the amu mass above.

In general a nucleus contains Z protons and N neutrons, where Z and N are integer numbers. The charge of the nucleus is Z times the elementary charge. It was pointed out in the first section that the atomic species is determined by Z alone. Nuclei of the same atomic species may, however, contain various numbers of neutrons. It is found, for instance, that hydrogen with Z equal to one may have N equal to zero, one or two. Such members of the same atomic species with different N values are called isotopes. It is customary to differentiate isotopes by a superscript equal to $Z + N$ following the chemical symbol of an atomic species. Thus the isotopes of hydrogen are H^1, H^2 and H^3. Frequently the Z value is indicated by a leading subscript (*e.g.*, ${}_1H^2$) but this subscript may be omitted since the chemical symbol also indicates the Z value. As further examples, the isotopes of oxygen may be mentioned, where Z equals 8 and N may be 6, 7, 8, 9, 10 or 11, and isotopes of uranium, in which Z is equal to 92 and N may have any value from 135 to 148.

Because isotopes have the same Z value and hence the same chemical behaviour, it is extremely difficult to separate them. Methods depending on the difference in mass, or N value, have been developed (*see* ISOTOPE) but these are much more expensive and less efficient than chemical processes.

The total number $(Z + N)$ of particles in the nucleus is called the mass number and is designated by A. The actual mass of a nucleus differs by a small amount from the sum of the masses of its protons and neutrons. It should be noticed that while the charge of the nucleus is exactly Z times the elementary charge, the mass of the nucleus is not obtainable in a similarly simple manner. A more detailed discussion of this remarkable fact will be given in the next section.

Among nuclei which contain few particles it is often found that the values of Z and N are nearly the same. Some of the most abundant isotopes found in nature such as ${}_2He^4$, ${}_6C^{12}$, ${}_7N^{14}$ and ${}_8O^{16}$ exhibit this phenomenon. As one goes to heavier nuclei the number of neutrons increases faster than the number of protons

in the nucleus. In uranium, for instance, the most abundant isotope has 54 more neutrons than protons.

In the 1960s there was no consistent theory to account for the forces which hold neutrons and protons together in the nucleus. To assure stability it must be assumed that these forces are in the main attractive. In the following there will be occasion to discuss some properties of these forces. Here it is sufficient to mention that these forces have extremely short range. The forces between neutrons and protons become negligible if the distance exceeds the order of magnitude of the nuclear diameter.

In addition to nucleons, that is, protons or neutrons, other particles are known to be emitted in nuclear transformations. Among these the α-particles and β-particles should be mentioned. These occur in the great majority of spontaneous nuclear disintegrations (spontaneous radioactivity) and historically they were the first to be observed. Nevertheless they are not considered to be primary constituents. In fact the α-particle may be considered to consist in turn of two protons and two neutrons, having a charge of two and a mass of approximately four units. The fact that α-particles so often occur as the product of nuclear disintegrations arises from the extraordinary stability of this particular arrangement of protons and neutrons.

The reason β-particles, which are either negative or positive electrons, are not considered regular constituents of the nucleus is more involved. According to the basic theory of atomic physics one cannot confine a particle of small mass, such as the electron, in a region as small as the nuclear radius without giving it an energy greater than the nuclear energy. In other words, the paradox occurs that the electron, if thus confined, must have an energy great enough to permit the particle to escape (*see* ELECTRON).

Nuclear theory describes the emission of negative or positive electrons as a process in which the negative or positive electron is created at the moment of emission. This concept becomes plausible when it is added that both the creation and annihilation of pairs of positive and negative electrons have been observed outside of nuclei. Thus these electrons cannot be considered immutable. Any attempt to assume the presence of these electron pairs in the nucleus leads to a complicated picture where any number of positive and negative pairs may be assumed to be present. In the accepted theory and for the following discussion, the presence of positive and negative electrons is ignored. Attention is confined to a model composed of neutrons and protons.

IV. NUCLEAR ENERGY

Observations of natural and artificial nuclear transmutations verify that the energies involved in nuclear reactions are of great magnitude. In fact, these energies are larger by a factor of 1,000,000 than the energies involved in chemical reactions. The neutrons and protons are bound together in nuclei about 1,000,000 times more strongly than atoms are bound together in chemical compounds or in the most stable crystals known. This great energy is closely associated with a general law of atomic physics according to which the binding or localization of a particle in a smaller region necessarily requires a greater binding energy.

The most direct way to measure nuclear binding energies is the study of nuclear reactions. Thus if one nucleus of the lithium isotope Li^6 is bombarded by a deuteron (the nucleus of heavy hydrogen H^2) two nuclei of helium are obtained. The reaction may be written similarly to an equation in chemistry:

$$Li^6 + H^2 \rightarrow 2He^4$$

To produce the reaction the bombarding deuterons must have enough kinetic energy to approach the lithium nucleus in spite of the electrostatic or coulomb repulsion of the two particles. The required energy is a few hundred thousand electron volts. (The electron volt, abbreviated ev, is the usual unit of energy in atomic and nuclear physics. It is the energy an elementary charge gains when it falls through a potential of one volt. One electron volt equals 1.6×10^{-12} ergs or approximately 1.5×10^{-18} of the work done in lifting a pound weight to a height of one inch.) The energy of the two resulting α-particles is equal to the energy of the deuteron plus an additional 22.17 million electron volts (Mev); *i.e.,* 22,170,000 ev. This difference in energy arises from the stronger binding of the neutrons and protons when combined in two helium nuclei, rather than in a lithium nucleus and a deuteron. The total binding energy of the helium nucleus compared with four free particles is 28 Mev or 7 Mev per particle. This is close to the largest binding energy per particle in any nucleus. The binding energy is a negative energy in the sense that one has to add energy to decompose a helium nucleus into neutrons and protons.

A determination of nuclear binding energies is often complicated because the reaction products have an excess internal energy, or excitation. The energy of excitation is retained by the nucleus for a very short time and then is emitted as γ-rays. These γ-rays are electromagnetic waves and are similar to light. There are, however, significant differences: γ-rays are emitted by nuclei, light is emitted by atoms; γ-rays carry away in a single process about 1,000,000 times more energy than light does; considered as a wave process, γ-rays have approximately 1,000,000 times shorter wave length than light. The most striking difference is that γ-rays are invisible though they produce physiological changes throughout the body, including the eye.

These γ-rays can enter actively into nuclear reactions. The absorption of γ-rays may excite a nucleus and furnish enough energy to disintegrate the nucleus. The most common result of such a disintegration is the splitting off of a neutron. If a nucleus of deuterium is bombarded by γ-rays with an energy of 2.2 Mev or more, the nucleus may distintegrate into a neutron and a proton, $H^2 + \gamma \rightarrow n^1 + H^1$. Since the energy of the γ-rays can be measured independently, this type of reaction furnishes an additional method for measuring binding energies. The reaction just described indicates a binding energy of 2.2 Mev for the deuteron.

The great amount of energy liberated in nuclear reactions makes it possible to use a method of energy measurement for nuclei which in other cases is impractical. The method of energy determination is based on a law obtained from theoretical arguments by Albert Einstein in 1905: whenever the energy of a system is changed, the mass is changed by a corresponding amount.

Energy changes in familiar objects are accompanied by exceedingly small changes in mass and, thus, the mass change postulated by Einstein was beyond observation. As an example consider a large spring weighing, say, 5 lb. and suppose a force of 3,000 lb. compresses the spring 6 in. The change of mass is 10^{-12}% of the mass of the spring. In chemical reactions the change in mass is a few orders of magnitude larger, but still too small for observation. Let us suppose a gram molecular weight (87.9 g.) of pyrite (FeS) is formed from iron and sulfur. The change in mass calculated from the heat energy released in the reaction, is 10.7×10^{-10} g. This corresponds to $\frac{1}{1,000,000,000}$ of 1% change in mass.

If now a neutron and a proton are considered as combining to form a deuteron, the energy liberated is 2.18 Mev per deuteron. This represents a difference in mass between the two particles when free and when combined in a deuteron of about a tenth of 1%. This difference is large enough to be measured accurately. Therefore, by reversing this procedure and measuring the difference in mass of separated and combined particles, the binding energy of the particles can be calculated. Thus the statement of the previous section, that the mass of a nucleus is not equal to the mass of the constituent particles, is explained by the mass change accompanying the energy change.

The relationship between mass and energy changes stated by Einstein may be written:

$$\Delta E = \Delta mc^2$$

where ΔE is the energy change expressed in ergs, Δm is the accompanying change of mass given in grams and c is light velocity, equal to 3×10^{10} cm. per second. If the energy is measured in million electron volts (Mev) and the mass is measured in the usual nuclear mass units ($\frac{1}{12}$ of the mass of the carbon atom) then the above relation gives a change of 1/931 nuclear mass units for every Mev change in energy.

As an example, consider the mass of deuterium or heavy hy-

drogen H^2 which is composed of a proton H^1 and a neutron n. In nuclear mass units

$$\text{mass of } H^2 = 2.01412$$
$$\text{mass of } H^1 = 1.00797$$
$$\text{mass of } n \;\; = 1.00867$$

Δm = mass of H^1 + mass of n − mass of H^2 = 0.00237. To convert this mass difference into a binding energy, multiply by 931 to give 2.2 Mev.

The choice of the unit of mass as $\frac{1}{12}$ of C^{12} can now be clarified. On this basis, the masses of other atoms are nearly whole numbers because in C^{12} the binding energy of the nucleons is similar to the binding energy in most other nuclei. Thus the mass of the nucleons in C^{12} is similar to the mass of the nucleons in other nuclei and if the total mass of C^{12} is set equal to the total number of nucleons contained in that nucleus, that is to 12, masses of other nuclei will be close to whole numbers.

V. FURTHER PROPERTIES OF NUCLEI

The particles that compose the nuclei (*i.e.*, the protons and neutrons) have a property which in a subtle way influences nuclear structure. These particles behave as though they were rotating around their own axes. There is no reason to believe that the statement just made can be taken in a literal sense. A picture as detailed as a definite axis localized in the particle is misleading. Nevertheless, neutrons and protons behave in many respects like rotating tops. The protons and neutrons carry an angular momentum which is half the unit of angular momentum in atomic physics. (The magnitude of unit angular momentum is 1.0544×10^{-27} erg-seconds and is usually called $\hbar$. This quantity is $\frac{1}{2\pi}$ times h, the quantum of action. *See* QUANTUM MECHANICS.) The angular momentum or spin of neutrons and protons behaves according to a certain set of rules. If the spinning motion around a given direction in space is investigated, it will always be found that the magnitude of the proton and neutron spin is one half of a spin unit, but that the sign of the spinning motion may have one of two opposite values. In other words the rotation may be clockwise or counterclockwise. The spin of nuclei may be considered as composed of the spins of the neutrons and protons in the nucleus. In the deuteron, which consists of a neutron and a proton, the spins of the neutron and proton seem simply to add, giving a total spin of one unit of angular momentum. The spin of the α-particle, which contains two protons and two neutrons, is equal to zero. In this case the spins of the constituent particles may be considered as partly clockwise and partly counterclockwise, so that the effects of the individual spins cancel. Indeed the spin was found equal to zero in all nuclei containing an even number of neutrons and an even number of protons (*see* NUCLEAR MOMENTS).

To the angular momentum caused by the spins of neutrons and protons there must be added the effect of the motion of these particles along their orbits within the nucleus. Consider the nucleus of the lead isotope containing 208 particles. The spin of this lead isotope has been found equal to zero. Now if a proton, which carries one half unit of spin, is added to the nucleus, the result is a nucleus of bismuth (Bi^{209}) and it might be expected that this nucleus had a spin of one half (zero, caused by Pb^{208} plus one half, caused by the proton). Actually the nuclear spin of Bi^{209} is nine halves. Therefore an additional spin or angular momentum is present which is caused by the motion of the proton in its orbit.

Spin values of nuclei show a few simple regularities. If the system contains an even number of particles of spin one half, the total spin is zero or an integral multiple of the atomic unit of angular momentum. If the system contains an odd number of particles of spin one half, then the system has a spin which is $n+\frac{1}{2}$ atomic units, where n is any positive integer or zero. This rule follows from the basic facts of atomic physics and from this rule was derived a strong argument against the presence of electrons in nuclei. According to earlier ideas the deuteron was considered as composed of two protons and an electron. Now the electron, like the proton, possesses a spin which is one half unit of angular momentum. This would give the deuteron an odd number of particles, each with one half unit of spin and, according to the statement made above, the deuteron would be expected to have $n+\frac{1}{2}$ spin units. Actually it has a spin of one unit. If, on the other hand, the deuteron is assumed to consist of a proton and a neutron, the observed spin value agrees with the rule given above.

The spin of neutrons and protons suggests the idea of an internal rotation. Whenever a charged particle like the proton rotates, one expects to find that the particle behaves like a magnet. Furthermore, from the charge and the spin may be predicted the strength of the magnet associated with the proton. The proton, indeed, behaves like a magnet, but the strength of the magnet is 2.79 times the predicted value. This has been considered as an indication that the proton is not quite a simple particle but can undergo some internal change.

According to the simplest ideas the neutron, not carrying a charge, should have no magnetic effects. This again turns out to be incorrect. The neutron carries a magnetic moment whose strength is 1.935 times the predicted strength for the proton and whose sign is opposite to that of the proton. This means that the magnetic properties of the neutron are those of a rotating negative charge. The discrepancies just mentioned do not contradict any rigorous predictions of atomic theory but only those conclusions based on the idea that neutrons and protons are particles of a very simple kind.

The magnetic moment of the deuteron is almost but not quite the sum of the magnetic moments of the proton and neutron. The fact that there is a slight deviation does not constitute a real difficulty if one considers the effect of the orbits of these two particles within the deuteron. In general all nuclei which have a spin have a magnetic moment. Detailed predictions are not possible because knowledge of the internal structure of nuclei is meagre.

Neutrons and protons have a further peculiarity in that two particles of the same kind are never found to occupy the same state. This rule bears the name of the Pauli exclusion principle. Within a nucleus orbits may be assigned to the nucleons (neutrons or protons). This assignment has to be made in such a manner that no more than two neutrons (or protons) shall be found in one orbit. Further, if there are two neutrons (or protons) in one orbit then these two particles must differ in spin; *i.e.*, one spin must be clockwise and one must be counterclockwise. It is possible for these two particles to be in the same orbit only because they differ in another one of their properties. The rule that two particles cannot be in the same state is thus satisfied. We see that the spin is significant for the details of nuclear structure. The possibility of two spin orientations allows the presence of two neutrons (or protons) in the same orbit of the nucleus.

The configuration of two neutrons or two protons in the same orbit seems to be stable so that, in general, a somewhat greater binding energy is found if the number of neutrons and the number of protons in the nucleus are both even; less if one or the other number is odd. The smallest binding energies are found for odd numbers of both neutrons and protons. In fact, only four stable isotopes are known with odd Z values and odd N values: H^2, Li^6, B^{10} and N^{14}. All others in this category are radioactive, indicating that the nucleus possesses sufficient energy to cause a transformation. Atomic species with even mass numbers are more abundant in the earth's crust and atmosphere than atomic species with odd mass numbers. The most abundant elements, Fe^{56}, Si^{28} and O^{16}, for instance, have even charges as well as even mass numbers. This is further evidence for the stability of the nuclei in question.

The simplest example of a very stable nucleus is helium He^4. As many particles as possible are put into the lowest orbit which can hold two protons and two neutrons. As mentioned before, the packing fraction of helium is large. Any additional particles, either protons or neutrons, must go into new orbits in which the binding energy per particle is less.

Atomic nuclei behave differently according to whether A is even or odd. If the mass number is odd, then two identical nuclei cannot occupy the same state. If the mass number is even, two identical nuclei can be placed in the same state. In the former

case we say that the nuclei obey Fermi-Dirac statistics; in the latter case we say that Einstein-Bose statistics apply. The two kinds of behaviour may be more exactly described by a statement concerning a function, the wave function (*see* QUANTUM MECHANICS), which describes the behaviour of particles, in particular the behaviour of pairs of identical particles. In the case of Einstein-Bose statistics this wave function remains unchanged if the positions of the identical particles are interchanged. In the case of Fermi-Dirac statistics a similar change leads to a change in sign of the function. Which of the two rules applies can be found experimentally by studying the rotation of a diatomic molecule containing the two identical nuclei. In this case the rotation actually brings about the interchange of the nuclei.

The application of these rules gives further evidence that neutrons and protons, rather than protons and electrons, are the proper constituents of nuclei. For example, take a nucleus of nitrogen $_7N^{14}$ which experimentally has been shown to obey Bose statistics. Assuming electrons and protons in the nucleus there would be present a total of 14 protons and 7 electrons. According to knowledge concerning protons and electrons, the interchange of two electrons or of two protons changes the sign of the function characteristic of the system. Thus the interchange of 14 protons and 7 electrons will invert the sign 21 times which amounts to a simple reversal of sign. This contradicts Einstein-Bose statistics which imply that interchange does not change the wave function. If on the other hand, $_7N^{14}$ is considered an assembly of 7 protons and 7 neutrons the interchange of the nuclei inverts the sign 14 times, which is equivalent to saying that the interchange leaves the sign unchanged.

It is seen, therefore, that a detailed consideration of finer nuclear properties like spins and wave functions gives the same final results as were obtained by more crude arguments: nuclei are built from neutrons and protons. To assume electrons in the interior of the nuclei would lead to a whole series of difficulties.

VI. BETA DECAY

A great number of nuclei are known to emit β-particles; *i.e.*, electrons or positrons. The emission of such a particle is accompanied by the transmutation of the nucleus. The resultant nucleus has the same mass number as the original one. If an electron has been emitted the nucleus in the final state will have one more positive charge than the original nucleus. If a positron is emitted the nuclear charge decreases by one unit. C^{11} is an example of a positron emitter, transforming into B^{11}, a boron isotope. C^{14}, another isotope of carbon, emits an electron and decays into nitrogen, N^{14}. An isotope of potassium K^{40} is capable of emitting either an electron or a positron and of transforming into calcium or argon, respectively.

The radioactive decay may be considered as a single act which takes an exceedingly short time, about 10^{-22} seconds. This is not, however, the time in which radioactive substances disappear. These elements have lifetimes which have been observed to vary from less than one-tenth of a second to more than 1,000,000,000 years. If there is an assembly of radioactive nuclei of a certain kind, then one half of these nuclei will have undergone radioactive decay in this lifetime, which is more specifically called the half life.

Each radioactive nucleus has a probability of undergoing the radioactive process per unit time and this probability is independent of the previous history. In particular, this probability does not depend on the length of time the radioactive nucleus has existed. Thus is obtained the law for a radioactive population according to which the radioactive population is halved in each lifetime.

One may assume that each β-decay is caused by one of two basic processes. These are the transformation of a neutron into a proton accompanied by the emission of an electron and the transformation of a proton into a neutron with the simultaneous emission of a positron. These processes are intrinsically slow but the reasons causing the transition or determining its rate are not yet known.

The transition of a free proton into a neutron cannot be observed. This transformation could be written:

$$H^1 \rightarrow n + e^+$$

where n stands for a neutron and e^+ is the symbol for a positron. The neutron is known to be heavier than the proton by 0.00[illegible] mass units and the total reaction products are heavier than the proton by 0.0019 mass units. The mass difference corresponds to an increase of energy during the reaction amounting to 1.77 Mev. If the neutron and positron gained kinetic energy during the reaction, the energy needed would be greater still. Thus at least 1.77 Mev must be supplied if the proton is to disintegrate into a neutron and a positron. Thus the reaction does not occur and the free proton is stable.

On the other hand a neutron can decay giving rise to a proton and an electron

$$n \rightarrow H^1 + e^-$$

The proton and electron together are 0.00081 mass units lighter than the neutron. According to the equivalence of mass change and energy change 0.754 Mev of energy are set free. The reaction described here is the simplest of all possible β-decays. It has been actually observed and its lifetime is approximately a quarter of an hour. Neutrons usually disappear much more quickly by reacting with other nuclei.

A β-decay process in a complex nucleus is described as one of the neutrons in the nucleus turning into a proton or one of the protons changing into a neutron, emitting an electron or positron respectively. This picture correctly describes the fact that the mass number of the nucleus remains unchanged while the charge of the nucleus changes by plus or minus one in the two cases mentioned. In complex nuclei it often does pay to convert a proton into a neutron plus a positron. One may consider, for instance, the decay

$$C^{11} \rightarrow B^{11} + e^+$$

While the sum of the masses of the neutron and positron is greater than the mass of the proton, the sum of the masses of B^{11} and e^+ is actually less than C^{11}. In the

$$C^{11} \rightarrow B^{11} + e^+$$

process a proton is turned into a neutron and a positron. The necessary energy is supplied by the greater binding energy of the resultant neutron. Thus the question of whether or not a nucleus can emit an electron or a positron depends on whether or not the transformation of a proton into a neutron or the transformation of a neutron into a proton can lower the energy of the system. In the energy balance must be included: the mass difference between the neutron and proton, the binding energy of these particles in the nucleus and the mass of the positron or electron which is to be ejected.

It may occur that there is not enough energy available to transform a proton within a nucleus into a neutron and to eject a positron at the same time. A nuclear transformation may nevertheless proceed. Instead of the emission of a positron the nucleus may absorb one of the electrons which are always to be found in the vicinity of the nucleus. In this way instead of having to supply an energy equal to the mass of the positron, one gains the energy corresponding to the similar mass of the electron. For instance, the isotope of manganese containing 54 mass units in its nucleus decays by capturing an electron and one obtains an isotope of chromium.

Consider two nuclei: one shall contain N neutrons and Z protons, the other $N-1$ neutrons and $Z+1$ protons. Add to the latter an electron. Of the two systems now considered, one or the other will have a higher energy and whichever one this is will not be stable but will transform into the other system. Nuclei of the same mass number are called isobars. Two isobars, differing by one charge unit, are called neighbouring isobars. The argument shows that of neighbouring pairs of isobars, one must be unstable.

There are a few known cases of neighbouring isobars where both nuclei seem to be stable. The reason for this apparent stability is the small energy difference between the isobars. It will be seen later that β-transformations in which little energy is released may have long lifetimes. In these cases β-processes may be so rare as to escape observation.

Now consider two isobars which differ by two charge units

There are many examples of such isobars. If all other isobars have higher energies than these two, then both of these isobars may be stable. In fact, a single transition will lead to a system of higher energy. A lowering of the energy could occur only if two β-transitions (*i.e.*, the ejection of two electrons or two positrons) occurred simultaneously. It has been mentioned above that the lifetime of radioactive nuclei is very long compared with the time an electron needs to cross the nucleus. This fact can be expressed by saying that the β-process is an improbable one. A process in which two electrons or two positrons undergo this improbable transition simultaneously is unlikely, and no direct measurement had detected it by the 1960s.

In the previous section it was stated that nuclei containing an even number of neutrons or an even number of protons have lower energies and are more stable than nuclei containing an odd number of neutrons or an odd number of protons. If a nucleus contains an odd number of neutrons and an odd number of protons then one may suspect that it can assume a more stable configuration in two ways: by emitting an electron and transforming a neutron into a proton or else by emitting a positron and transforming a proton into a neutron. In either case an even number of protons and neutrons will be obtained. It is frequently observed that a nucleus of even mass number and odd Z value emits both electrons and positrons. One example is K^{40} mentioned above.

In a stable nucleus a certain balance exists between the number of neutrons and the number of protons. For a given number of protons the neutron number may vary between narrow limits. If an excess of neutrons is present an electron will be emitted and one of the neutrons turns into a proton. The product will be a stable nucleus or at least one which has a smaller neutron excess. In a like manner, if the nucleus has a proton excess, the nucleus will emit a positron, transforming a proton into a neutron.

These facts can best be summarized in two curves, as shown in figs. 1 and 2. For isobaric nuclei with odd mass number it does not make much difference whether Z is even or odd. In the first case we have an even number of protons but an odd number of neutrons. In the latter case the number of neutrons is even; that of the protons is odd. The result is a smooth dependence of the energy on Z as shown in fig. 1. The arrows indicate possible transitions. For isobaric nuclei with even mass number nuclei with even Z values have a lower energy than nuclei with odd Z values. The former contain an even number of protons and an even number of neutrons, the latter an odd number of protons and an odd number of neutrons. The resulting energies are shown by the curves in fig. 2. The transitions are again indicated by arrows. The figures illustrate that for even mass number one may expect more than one stable isobar, while for odd mass number only one isobar is likely to be stable.

FIG. 1.—SCHEMATIC REPRESENTATION OF THE ENERGY OF ISOBARS AS A FUNCTION OF ATOMIC NUMBER: ODD MASS NUMBER

It would be expected that when a β-ray is emitted from a nucleus it should carry away with itself in the form of kinetic energy the difference in energy between the original and the resulting nuclei. This is not so. The β-particles emitted from one definite nuclear species have various energies: some carry very little energy, most of them about one-half or one-third of the expected energy and a few nearly all of that energy. None are found to carry an energy in excess of the expected amount.

The fact that β-rays of a definite decay process have varying energies is surprising. It has not been possible to explain the varying energies of β-rays by the assumption that β-rays come from nuclei differing to a certain extent in their properties. Neither did it prove possible to assume that β-rays of varying energy leave the nucleus with correspondingly varying residual energy. On the other hand, the law of conservation of energy requires that the energy difference between the expected and the actual amount should appear in some other form (*see* ENERGY).

FIG. 2.—SCHEMATIC REPRESENTATION OF THE ENERGY OF ISOBARS AS A FUNCTION OF ATOMIC NUMBER: EVEN MASS NUMBER

The simplest explanation of the facts described above is the following: in the decay process not one but two particles are emitted from the nucleus. One of them, the β-ray, is an electron carrying a positive or negative charge. The other one is called the neutrino. It carries no charge and has no intrinsic mass, but it carries away the missing amount of energy from the nucleus in the form of kinetic energy (*see* PARTICLES, ELEMENTARY).

The assumption that a neutrino is emitted together with the β-ray has helped to explain a number of peculiarities of the β-process. First, the neutrino hypothesis does not merely explain that β-rays from the same decay process have various energies, but it is also capable of accounting for the frequencies with which various β-energies occur.

On the basis of the neutrino theory it was also possible to predict that the probability of β-decay increases with the fifth power of the energy released in the decay. In other words, the lifetime of the radioactive nucleus is inversely proportional to the fifth power of the maximum energy of the β-particle. This law is an approximate one and holds only for the simplest type of β-decay, for sufficiently high energies and for similar nuclei. The more complex β-disintegrations seem to have a decay probability which differs from the probability predicted by the simple theory. These anomalous β-decay processes have smaller decay probabilities and considerably longer half lives than the normal processes.

There is a further group of phenomena which can be explained with the help of the neutrino hypothesis. These are the changes of nuclear spin and nuclear statistics during a β-decay. It has been stated previously that a nucleus or, more generally, an association of particles will have a spin which is an even or odd multiple of one-half the elementary unit of spin according to whether the system contains an even or odd number of particles, each carrying one-half unit of spin. Now a β-ray carries one-half of a spin unit and so do the neutrons and protons of which the nucleus is built. If it is assumed that in a β-process the β-ray is emitted by itself, then the number of particles carrying one-half unit of spin would have increased by one during the process. It would be necessary to assume that the total spin of the system changes. It is, however, a very general rule that the spin of a system left to itself, like a nucleus undergoing a β-decay, must not change. The rule of conservation of spin is indeed almost as strongly supported by experience as the rule of conservation of energy. The emission of a single electron would violate spin conservation as well as energy conservation. If it is assumed that together with the electron a second particle, the neutrino, is emitted and, if it is also assumed that the neutrino carries a half unit of spin, the difficulty disappears.

An analogous argument can be put forward for nuclear statistics. It has been mentioned that a nucleus or system of particles has Einstein-Bose statistics or Fermi-Dirac statistics, respectively, if it contains an even or odd number of particles which themselves obey Fermi-Dirac statistics. Protons, neutrons and electrons do behave according to Fermi-Dirac statistics. If the β-process consisted of the emission of an electron only, the total number of particles would change by one and during the process the system would change from Einstein-Bose statistics to Fermi-Dirac statistics or vice versa.

Such a change in statistics is completely alien to our notions about the composition of matter. For instance, two systems obeying Fermi-Dirac statistics cannot be in the same state, but two

systems obeying Einstein-Bose statistics tend to be in the same state. The transformation of a system from one statistics to another would imply a changed behaviour of similar systems. This change would be so peculiar that we find ourselves unable to incorporate it in the mathematical laws which describe physics in the atom. If it is assumed, however, that together with an electron a neutrino is emitted and that the neutrino obeys Fermi-Dirac statistics, the difficulty is resolved. Two particles obeying Fermi-Dirac statistics are emitted in the process and therefore a change in statistics is not expected.

In addition to carrying energy a neutrino also carries away a momentum which can be calculated from the energy which it possesses. If a nucleus which was originally at rest suffers a β-decay, the momenta carried by the decay products must add up to zero. Since the neutrino is invisible, the momenta of the observable particles do not cancel. By measuring these momenta, one can obtain the momentum which the neutrino must have carried. This difficult experiment has been performed and indicates that the neutrino carries the expected momentum.

Finally, since neutrinos are emitted in β-decays, one can show that they in turn stimulate β-disintegration when they impinge on otherwise stable nuclei. Since the β-disintegration is an exceedingly improbable process, this stimulating effect of the neutrinos is very weak. By using the large neutrino fluxes which are emitted by big nuclear reactors, it has been possible to obtain some indication of this stimulating influence of the neutrino. The evidence for the existence of neutrinos is thus partly indirect and partly based on extraordinarily difficult experiments. Nevertheless, the existence of neutrinos can hardly be questioned.

VII. ALPHA DECAY AND SPONTANEOUS FISSION

In the β-decay a nucleus emits particles which, according to our model, the nucleus does not actually contain. The electron and neutrino emitted in the process may be considered as born at the moment of emission. In other radioactive processes, which are discussed now, particles are ejected from the nucleus which were present in a different configuration before the decay took place.

In another respect all radioactivities are similar: the half-life of a radioactive nucleus is always exceedingly long as compared with times in which nuclear rearrangements could be expected to take place. The ratio of these times is in most cases larger than 10^{20} and sometimes even much greater than that. The reason for such long lifetimes is unknown in the case of β-processes. The reason must, it is thought, lie in the nature of the birth process of electron-neutrino pairs. In the case of other radioactive processes, such as α-decays and spontaneous fission, G. Gamow, E. U. Condon and R. W. Gurney have satisfactorily explained the long lifetimes.

In an α-disintegration a nucleus emits an α-particle, which is itself a very stable nucleus containing two neutrons and two protons. α-active nuclei are encountered among the nuclei which carry the highest charges. In these nuclei the repulsion between the α-particle and the rest of the nucleus results in an energy release which is not only sufficient to overcome the short-range attraction between the α-particle and the rest of the nucleus, but also gives the α-particle a kinetic energy of a few million electron volts.

The spontaneous fission process is also observed in the most heavily charged nuclei. In this process a nucleus divides into two approximately equal fragments which, under their mutual coulomb repulsion, fly apart with a kinetic energy close to 200 Mev.

Both in the α-decay process and in the spontaneous fission process there is an important obstacle to the disintegration. The initial part of the disintegration, instead of releasing energy, actually would require some added energy which is not available in the cases considered. Thus an α-particle at a large distance from the nucleus has a lower potential energy than when it is inside the nucleus. However, an α-particle outside the nucleus but close to it (*i.e.*, when it is in an intermediate state of the disintegration process) has a higher potential energy than when either in the *initial* state inside the nucleus or in the final state when it is far away. This is, indeed, not surprising. In order to bring the α-particle from the initial state to the intermediate state it is necessary to do work against the short-range forces holding the α-particle in the nucleus. Again, if it is desired to bring the nucleus from the final state into the intermediate state it is necessary to do work against the coulomb repulsion. It is seen that the α-particle has to overcome a potential barrier in order to get from the initial state to the final state. Since there is not enough energy available to do this the process should be impossible from the point of view of classical mechanics. In the mechanics which is valid for particles of atomic and subatomic size it is not possible to localize sharply any particle without giving it a large amount of energy at the same time. Applying this kind of mechanics to the motion of the α-particle it is found that the α-particle, instead of staying in the nucleus, will leak through the potential barrier. While this statement is in conflict with our intuition concerning the behaviour of particles, it must be accepted on the basis of extensive experience of atomic and subatomic physics. The penetration of the potential barrier by these particles is closely related to the fact that these small particles, as long as they have a well-defined energy, cannot be sharply located on one side of the barrier.

The necessity of penetrating a potential barrier in the process of disintegration explains the long life and small disintegration probability of the α-active substances. This surprising penetration of a potential barrier becomes extremely improbable as the height or the breadth of the barrier or else the mass of the particle in question becomes bigger. The result is that an α-particle may approach the surface of the nucleus 10^{20} times or more often before it actually succeeds in leaving the nucleus. A further consequence is that relatively small differences between α-active substances cause great changes in the decay probability. The most important factor influencing the decay probability is the energy released in the α-process. If the decay energy is high, that energy will approach more closely the top of the barrier. The result is a greatly increased penetration probability and a greatly increased rate of decay. In fig. 3 the half-lives of the α-active nuclei are plotted against the energy released in the α-decay. While the range of energies for which observations exist extends only from 3.5 to 9 Mev, the corresponding lifetimes are of quite different orders of magnitude. They range from 10^{-7} seconds to 10^{10} years, a time longer than the age of the earth. In order to plot all of these different times in a single graph a logarithmic scale is used. This means that each unit on the vertical scale stands for a factor ten in the lifetime. Next to the ordinate the half-life values are entered in units of seconds and also in units of years. The dots in the figure represent observations for various α-active nuclei. The curve was obtained by applying the theory of barrier penetration to the α-decay process. While this theory disregards all finer details of nuclear structure it is still in excellent agreement with the general trend of the observed points.

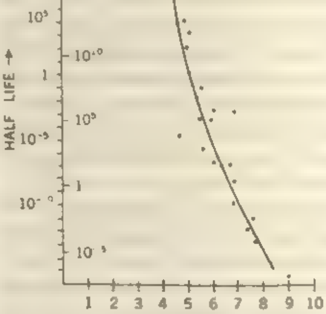

FIG. 3.—HALF-LIFE FOR α-DECAY AS A FUNCTION OF α-RAY ENERGY. (SOLID CURVE IS THEORETICAL)

An entirely similar situation is encountered in the theory of spontaneous fission. Here the nuclear division must be considered as the end result of a process in which an originally spherical nucleus first takes on the form of an ellipsoid, then that of a dumbbell, then that of two smaller and nearly spherical pieces close to each other which finally fly apart to form the fission fragments. The initial distortion in this process requires an energy which, as in the case of α-decay, is actually not available. A potential barrier must be overcome if the fission is to proceed. This potential barrier is probably less high than the one encountered in α-decay. The particles to be moved through this barrier, however, are

fission fragments, containing about 100 neutrons and protons instead of the 4 nuclear units contained in an α-particle. The fact that a much bigger mass must be moved through a potential barrier decreases the disintegration probability. The uranium isotope U^{238} is among the α-active nuclei of longest life with a half-life of 4.5×10^9 years. Yet this nucleus will have more than 1,000,000 times greater probability to decay by an α-process than to undergo spontaneous fission.

VIII. METASTABLE NUCLEI

If a nucleus is not in its lowest state of energy, it is said to be in an excited state. Lifetimes of such excited states, as a rule, are short and the nucleus falls into the lowest energy state, emitting the excess energy as radiation. The time required for this process in many cases is of the order of 10^{-14} seconds. The energy emitted leaves the nucleus in the form of γ-radiation.

If the excitation energy is relatively small (*i.e.*, of the order of 100,000 v.) the lifetime of the excited state is relatively longer, in some cases exceptionally long. These transitions are similar to the anomalous β-decay processes which, as has been pointed out, have longer half lives than the normal β-decay processes. The exceptional nuclei are called metastable. Their lifetimes are often of the order of a few seconds, some much longer. An isotope of krypton, Kr^{83}, for instance, has a lifetime of 113 minutes. Two γ-ray energies have been observed: 0.029 Mev and 0.046 Mev. A long lifetime, 13.8 hours, is also shown for Zn^{69}. The γ-ray energy for this metastable state is 0.45 Mev.

Often such nuclei apparently emit electrons rather than γ-rays. The reason for this behaviour is that the electromagnetic radiation transmits its energy to an electron before the radiation leaves the immediate vicinity of the nucleus. While this electron originally has been a part of the same atom to which the nucleus belongs, it should be emphasized that the electron never was a part of the nucleus. That is, the electron is not actually emitted by the nucleus.

The electromagnetic energy has been converted to kinetic energy of an electron which was formerly bound to the atom. These electrons are called conversion electrons. These conversion electrons can easily be distinguished from β-rays because their energy is well defined, while the electrons emitted from nuclei always have a continuous range of energies. Conversion electrons very frequently accompany γ-rays, but they are found with particularly high probability in the γ-processes of long lifetime which were described above.

IX. NUCLEAR REACTIONS

Up to now, this discussion has considered in some detail processes in which a nucleus undergoes a spontaneous transition. There exists a much more varied class of nuclear transformations, namely the transformations which occur when a nucleus collides with another nucleus or some other particle. Every nucleus is, of course, in practically continuous contact with the electrons which together with the nucleus make up an atom. Stable nuclei are not capable of reacting with these electrons. β-active nuclei may absorb an external electron, as described above. This process is closely related to ordinary β-activity and it has been treated above, under *Beta Decay*. This section will consider the collisions of a nucleus with a fast electron, with a γ-ray, with another nuclear particle, such as a neutron, proton, deuteron, a heavier nucleus or with one of the unstable particles called mesons, which themselves are generated in nuclear collisions.

Bombardment of nuclei by fast electrons throws the nuclei into excited states whose characteristic γ-radiations have been studied. The collision of a nucleus with a γ-ray may also result in the excitation of that nucleus. If the energy of the γ-ray is sufficiently high, absorption of the γ-ray will be followed by a nuclear disintegration, most frequently the emission of one or more neutrons. It has been observed that γ-rays of a characteristic resonance energy are particularly absorbable by nuclei. This resonance energy is in the neighbourhood of 20 Mev. It is somewhat higher for light nuclei and somewhat lower for heavy nuclei.

If a reaction between two charged nuclei is to be studied at least one of these particles must have considerable kinetic energy. Otherwise the electric repulsion prevents the nuclei from approaching close enough to react. According to classical mechanics one would expect that the approaching particles must possess a minimum kinetic energy if they are to get in contact with each other and if they are to react. Actually this simple argument is incorrect. The approach of two charged particles is more involved and is similar to the process of α-decay in which two charged particles are moving apart. Even if sufficient energy is not available for the two particles to come into contact according to the classical picture there remains a small probability for the collision partners to penetrate through the barrier separating them. This probability rapidly becomes smaller as the energy of approaching particles decreases. At small energies the resulting nuclear reactions occur so rarely that they become practically unobservable.

It follows that reactions between nuclei are more easily observed when the nuclei contain relatively low charge. The reactions which can be studied at lowest energies are those between two singly charged deuterium nuclei: $H^2 + H^2 \rightarrow H^1 + H^3$ and $H^2 + H^2 \rightarrow He^3 + n$. These reactions have actually been followed down to 10,000 ev bombarding energy; *i.e.*, to the energy of a "soft" X-ray tube (*see* DEUTERIUM AND TRITIUM).

Reactions between light nuclei and protons are of particular interest because according to present ideas such reactions are responsible for energy production in the sun. In some of these reactions the proton attaches itself to a nucleus and an α-particle is emitted. An example of such a reaction is $Li^7 + H^1 \rightarrow He^4 + He^4$. A second example is $N^{15} + H^1 \rightarrow C^{12} + He^4$. When more heavily charged nuclei are bombarded by protons, the emission of α-particles becomes less likely. The reason for this is similar to the reason for the long life of α-emitters. The α-particle to be emitted must surmount a high barrier. This process, therefore, becomes improbable and the nuclear reaction is likely to take another course (*see* STAR: *Stellar Structure*).

One of these other possibilities is that the proton attaches itself to the nucleus and a neutron is emitted instead. This has been observed in collisions between lithium and protons. The reaction proceeds according to the relation: $Li^7+H^1 \rightarrow Be^7+n$. One notices that the colliding partners are the same as those which lead to two α-particles according to: $Li^7+H^1 \rightarrow He^4+He^4$. It actually is frequently true that a collision between two nuclei gives rise to several competing processes. Depending on the energy of the colliding particles one or the other of these reactions will occur either preferentially or exclusively. For instance, if the energy of the bombarding proton is less than 1.6 Mev, neutron emission does not occur because the sum of energies of Be^7 and a neutron is higher than the energy of the Li^7 and H^1 by just 1.6 Mev. On the other hand, the formation of two α-particles releases energy and can, therefore, proceed at any energy of the bombarding protons providing the proton gets close enough to the lithium to react with it. Since the neutrons are unaffected by electrostatic repulsion the ejection of a neutron by a proton may proceed without difficulty in more heavily charged nuclei. An example is:

$$Sb^{121}+H^1 \rightarrow Te^{121}+n$$

A proton may also simply attach itself to the nucleus with which it collides. This happens in the reaction

$$C^{12}+H^1 \rightarrow N^{13}+\gamma$$

In reactions of this type the binding energy of the proton in the nucleus is released in the form of γ-rays. This energy release is a relatively slow process. It takes, as a rule, only 10^{-14} seconds, but the time in which a neutron or an α-particle could be released by the reacting partners is very much shorter still, namely 10^{-20} seconds or less. Thus, the reaction between N^{15} and protons could, in principle, lead to the formation of O^{16} according to the scheme $N^{15}+H^1 \rightarrow O^{16}+\gamma$. The reaction mentioned above $N^{15}+H^1 \rightarrow C^{12}+He^4$ seems, however, to occur almost exclusively because this type of rearrangement between the reaction partners happens to take a much shorter time. On the other hand, $C^{12}+H^1 \rightarrow N^{13}+\gamma$ can occur more readily because in this case no competing process exists as long as the proton does not have too high an energy. Actually both the ejection of an α-particle or of a neutron from

the carbon nucleus would require a very high proton energy.

When a nucleus is bombarded by a deuteron, reactions similar to those discussed above occur. In particular, neutrons and α-particles are found among the reaction products. The reaction to which deuteron bombardment most often leads is the ejection of a proton. This reaction occurs with relative ease even if the bombarded nucleus has a high charge. The deuteron does not need actually to penetrate to the surface of its target. When the coulomb repulsion becomes too strong the deuteron decomposes into a neutron and a proton. The neutron suffers no repulsion and reaches the surface of the nucleus while the energy of the reaction is carried away by the proton.

Among reactions with heavier nuclei mention shall be made only of the reactions with α-particles. Because of the availability of natural α-rays these were the first to be observed; they were of further historical importance in that they led to the discovery of the neutron. One of the easiest and earliest methods of producing neutrons is by the reaction $Be^9+\alpha\rightarrow C^{12}+n$. In reactions with more heavily charged nuclei α-particles can participate only if they carry a rather high kinetic energy. Even more kinetic energy would be required if the bombarding nucleus had more than two charge units.

When a nucleus is bombarded with neutrons whose energy is in excess of 1 Mev, the result is not very different from the reactions that occur when fast deuterons or protons are the bombarding particles. Of course the neutrons, not being repelled by the nuclear charge, can penetrate into heavy and light nuclei with equal ease. The result again may be the attachment of a neutron to the nucleus accompanied by the emission of a γ-ray. An example is $Au^{197}+n\rightarrow Au^{198}$. The resulting isotope of gold is unstable and decays to mercury. The fact that the resulting gold isotope is radioactive makes it easy to establish that the reaction has actually occurred in a bombarded gold sample.

A second type of reaction with neutrons is the re-emission of the original neutron plus the emission of another neutron. The first neutron serves to knock the second neutron out of the bombarded nucleus. Since the second neutron is strongly bound only bombarding neutrons carrying high energy produce this reaction. The result of this reaction is an isotope of the original bombarded nucleus having a mass number diminished by one. The reaction

$$O^{16}+n\rightarrow O^{15}+n+n$$

may serve as an example.

In another type of reaction the neutron attaches itself to the nucleus and a proton is emitted instead. This is illustrated in the reaction

$$Zn^{66}+n\rightarrow Cu^{66}+p$$

While in this reaction the neutron is free to penetrate into the nucleus, the proton encounters a potential barrier on its way out. This barrier again results from coulomb repulsion and is higher for more heavily charged nuclei. Thus this reaction will occur with considerable probability only in light nuclei or else in those cases where the outgoing proton receives a rather high energy, sufficient to overcome the potential barrier just mentioned.

The same situation is encountered if an α-particle is emitted after the neutron has attached itself to the bombarded nucleus. As an example we may mention the reaction:

$$N^{14}+n\rightarrow C^{11}+\alpha$$

The reaction products have, in this case, a greater total mass than the original neutron and nitrogen. The mass difference corresponds to 2.25 Mev and therefore only neutrons having an energy greater than 2.25 Mev will be able to produce this reaction. It might be noted that in this case neutron bombardment also gives rise to the reaction:

$$N^{14}+n\rightarrow C^{14}+p$$

This reaction releases energy, and therefore proceeds at low as well as high neutron energies. The two reactions just discussed are competing processes. This situation is quite typical. If the bombarding particle does not have much energy few types of reactions can take place. At higher bombarding energies more reactions become possible.

Among the nuclear reactions induced by neutron bombardment the fission of uranium and thorium are of greatest practical importance. As stated above, uranium may disintegrate into two roughly equal fragments even of its own accord. The rearrangement of nuclear matter, however, which leads to this fission process requires an initial investment of energy. Thus the spontaneous fission can take place only if the resultant particles penetrate a potential barrier, which is an exceedingly improbable process. If a uranium or thorium nucleus is hit by a neutron, the neutron attaches itself to the nucleus and delivers to the nucleus the binding energy of the neutron, amounting to several Mev. This energy sets the particles of which the nucleus is composed into motion. This motion may lead to the rearrangement necessary to initiate the fission process. It is interesting to note that the common isotopes of thorium and uranium, Th^{232} and U^{238}, require neutrons of relatively high initial energy if fission is to be produced. The reason is that fission is a quite improbable process unless the neutron furnishes enough energy to deform the nuclear matter to a point from where the further process is a "downhill" motion; *i.e.*, a motion which is connected with a diminution of potential energy. If a neutron fails to deliver sufficient energy to lift the nucleus to the top of the potential barrier, the fission process becomes quite improbable. In this case it is more likely that the excited nucleus will get rid of its energy either by re-emission of the original neutron or by the emission of a γ-ray. In the former case the neutron reverts to the original bombarded nucleus; in the second case, the reaction product is an isotope of the bombarded nucleus which contains an additional neutron. There is no reason why nuclear fission could not be produced by proton and deuteron bombardment as well as neutron bombardment. The protons and deuterons are, however, strongly repelled by the electrostatic field of the heavily charged uranium nucleus. Thus only highly energetic protons and deuterons are capable of producing fission.

Neutrons with an energy of 20 Mev or more are capable of producing fission in bismuth, lead and even lighter nuclei. In these cases fission probably results after a few preliminary processes have occurred. First the neutron communicates to the nucleus a high excitation energy. Thereafter the nucleus emits several particles, mostly neutrons. This process is called spallation. Neutrons escape preferentially because they need not overcome any potential barrier. Thus the nucleus is left with an unusually great excess of protons. The charge of these protons facilitates fission and a certain fraction of the bombarded nuclei actually divide into two similar particles.

The neutron reactions discussed thus far are usually referred to as fast neutron reactions. In contrast to these, slow neutron reactions signify events in which nuclei are hit by neutrons carrying a fraction of an electron volt. The neutrons in a typical slow neutron reaction possess about 100,000,000 times less energy than the neutrons in a fast neutron reaction. These slow neutron reactions are in many respects quite different from reactions in which only fast particles participate. These will be discussed in some detail since they play an important part in the release of atomic energy for useful purposes.

All the neutrons observed are products of nuclear reactions. Originally these neutrons are fast. Slow neutrons are obtained by allowing the fast ones to make a considerable number of collisions with other nuclei. There are many nuclei with which neutrons can collide repeatedly without causing nuclear reactions and without being captured by these nuclei. Frequently the only possible process is an elastic collision in which the neutron gives some of its energy to the collision partner. If, for instance, a neutron collides with a proton it loses roughly one-half of its energy in each collision. In collisions with carbon nuclei the neutron is apt to lose one-sixth of its energy. As a result 20 collisions with protons will suffice to deprive a neutron of all but one-millionth of its original energy and roughly 100 collisions with carbon nuclei produce the same result.

The energy loss, however, will not proceed indefinitely. All nuclei of the atoms in and around us participate in a disorderly motion that is produced by the heat energy shared by all bodies. The average energy of the particles at room temperature is about

$\frac{1}{40}$ ev. When the neutrons are slowed down to this energy they will cease, on the average, to lose energy in collisions. They will rather participate from then on in the general thermal agitation of all particles. Neutrons of about $\frac{1}{40}$-ev energy are therefore often called thermal neutrons. The term slow neutrons is not restricted to the thermal neutrons but includes those of somewhat higher and lower energies. Thermal neutrons, however, are typical representatives of the class of slow neutrons. It is of interest to note that thermal neutrons move with an average velocity of 1.3 mi. per second. It seems peculiar to call such neutrons slow but they are slow compared with neutrons of 1 Mev energy whose velocity is little less than 10,000 mi. per second.

Reactions of slow neutrons differ from other nuclear reactions in several important respects. Slow neutrons may be absorbed very effectively by certain appropriate materials. Thus $\frac{1}{100}$ in. of cadmium is sufficient to absorb most of a beam of slow neutrons. A beam of fast neutrons, on the other hand, penetrates approximately two inches of any condensed material before the beam is strongly absorbed or otherwise altered in its properties. Slow neutrons are not absorbed so strongly by all kinds of nuclei. In collisions with nuclei such as carbon or lead, for instance, slow neutrons are hardly ever absorbed. Furthermore a reaction between a slow neutron and a nucleus depends on the energy of the neutron in a very selective manner. The reaction of neutrons with indium nuclei are very characteristic in this respect. A thermal neutron beam is effectively absorbed by an indium foil, while neutrons of one volt energy are considerably less affected. Neutrons of a sharply defined energy of 1.44 ev are more strongly absorbed in indium foils than neutrons of any other energy.

The peculiar behaviour of neutrons described above is the result of two facts. One is that slow neutrons spend a longer time in the neighbourhood of each nucleus and are more likely to be captured in a single collision. The second fact is the existence of compound nuclei which are formed by the initial fusion of the reaction partners and which possess well-defined energy levels. As an example let us continue to consider the reaction of indium with slow neutrons. If a neutron is bound to an indium nucleus an energy of approximately 8 Mev is released. At the time that a slow neutron enters the binding energy appears as agitation of the compound nucleus. The designation of compound nucleus refers to this original agitated nucleus which is formed as a first step in the nuclear reaction.

The energy of agitation is not arbitrary but can be one of a certain number of rather sharply defined values. If the small kinetic energy of the incident neutron added to its big binding energy is just sufficient to form a compound nucleus in one of these sharply defined energy states then the neutron will enter the nucleus with a high probability. The energy at which the neutron enters with the greatest probability is called the resonance energy. The more the energy of the neutron differs from this resonance energy, the smaller will be its chance to enter the nucleus. A change in neutron energy of only one-tenth of an electron volt is sufficient to alter considerably the chance of the neutron to participate in the reaction.

These sharply defined levels of compound nuclei do not occur in the case of light atomic nuclei. This fact has been explained by a typical law of atomic physics according to which sharply defined energy levels occur only if these energy states have comparatively long lifetimes. If a state has a lifetime of 10^{-21} seconds (which is a typical period for nuclear rearrangements) then energy levels cannot be defined with a precision less than 1,000,000 v.

The sharply defined energy of compound nuclei indicates a lifetime more than 1,000,000 times longer than the time for a simple rearrangement. Why such long lives should occur when a slow neutron enters a nucleus of high weight, such as indium, may be understood in the following manner. When a neutron of small energy enters a nucleus its considerable binding energy is promptly shared as energy of agitation by the many particles of the nucleus. If the original neutron is to leave the nucleus again all of this energy must once more be concentrated on a single neutron. This process is unlikely and, on the average, takes a long time. If the nucleus consists of few particles then it will be more easily possible to concentrate the energy on a single one of these particles. On the other hand, if we have started with a fast neutron, then it will not be necessary to return to this neutron all of its energy to enable the original neutron to escape again.

Once a slow neutron has entered a nucleus and has found a compound state several reactions are still possible. The most probable of these is the emission of the binding energy of the added neutron in the form of γ-radiation. In this way an isotope of the original bombarded nucleus is formed. Thus we have the reactions:

$$H^1+n \rightarrow H^2+\gamma$$
$$O^{16}+n \rightarrow O^{17}+\gamma$$
$$U^{238}+n \rightarrow U^{239}+\gamma$$

The last reaction will be referred to again in discussing the utilization of nuclear energy.

Among the lightest and the heaviest nuclei there are a few more important reactions following neutron capture.

Protons are emitted in the reaction of slow neutrons and nitrogen:

$$N^{14}+n \rightarrow C^{14}+p$$

The resulting β-active isotope of carbon is most useful in the study of reactions in organic chemistry and biochemistry. This isotope of carbon is formed in small amounts by cosmic rays and occurs, therefore, as a "natural" activity. Its half-life is 5,568 years. By measuring the carbon activity in an archaeological sample one may determine the age of that sample (*see* RADIOCARBON DATING; GEOCHRONOLOGY).

In reactions with Li^6 and B^{10} the absorption of a slow neutron results in the emission of an α-particle, according to

$$Li^6+n \rightarrow H^3+He^4$$
$$B^{10}+n \rightarrow Li^7+He^4$$

These reactions are important because these nuclei, especially B^{10}, are very strong neutron absorbers. In contrast to indium, which preferentially absorbs neutrons of 1.44 ev energy, all neutrons are absorbed by Li^6 and B^{10}, but slow neutrons, which spend more time in the neighbourhood, are absorbed with greater probability.

The fact that slow neutrons are strongly absorbed by particular materials permits the regulation of the number of slow neutrons and allows or denies them access to certain parts of materials. The control of the energy release in chain-reacting materials is based on this property of slow neutrons.

The energy released by slow neutron capture is insufficient to cause fission in any isotope which occurs with great abundance in a natural substance. In some materials, particularly in U^{235} and Pu^{239}, slow neutrons do give rise to fission. The consequence of this fact will be discussed later.

New high-energy accelerators have produced protons carrying several hundred Mev. Bombardment of nuclei by such protons often gives rise to disintegration into several fragments. It is remarkable, however, that more gentle interactions are not unusual. Thus a proton may collide with a nucleus without changing its energy or momentum to a great extent. In the collision, however, the proton turns into a neutron, leaving its charge behind in the nucleus with which it collided. It also happens quite often that the impinging proton picks up a neutron during its contact with a nucleus. The bombarding particle changes, therefore, into a deuteron but continues on its path without any great deflection or loss of energy.

The most important result of experiments in the several-hundred-Mev range has been the production of mesons. These are unstable particles, some of which are neutral while some carry a unit of positive or negative charge. A considerable variety of these particles has been discovered. They differ not only in their charge but also in their masses, spins, lifetimes and modes of decay. At least one class of these mesons, the π mesons (pi mesons), is closely connected with the forces that bind the nucleons into stable nuclei. This connection will be discussed below.

It has become customary to designate mesons as well as nucleons, electrons and neutrinos as "elementary particles." With the increase in the number of these particles it becomes likely

that at least some of them are no more elementary than atoms are indivisible. It is expected that some simple and general laws of physics will eventually be found to explain the properties of all these particles.

X. SUMMARY OF NUCLEAR PROPERTIES

The nuclear reactions described in the last section led to the discovery of a very great number of previously unknown radioactive nuclei. These, together with the nuclei that occur in nature, are collected in the accompanying chart of properties of the nuclides. In this chart each nucleus is represented by a square. For instance, in the first section of the chart (second row from the bottom) the isotopes of hydrogen appear. The charge number 1 and the atomic symbol H (for hydrogen) appear at the left of the row. The first square corresponds to a proton. In the square is found the mass number for the proton, which is 1, and below it the abundance of protons in ordinary hydrogen is indicated. The figure 99.985 means 99.985% of ordinary hydrogen consists of light hydrogen or protons. The square to the right of the proton corresponds to heavy hydrogen or deuterium with a mass number 2. Its abundance in ordinary hydrogen is 0.015%, which is also entered. The third square in the row corresponds to tritium, the radioactive isotope of hydrogen. This isotope does not occur in nature and so the second line in the square contains a zero. Instead the half-life, 12.26 years, has been entered in the third line. The arrow attached to this isotope shows that the nucleus decays to He^3, the light isotope of helium, occurring in the next row. At the bottom of each column is the number of neutrons in the nuclei. Therefore, below the proton is found zero, indicating that this lightest isotope contains no neutrons. Below deuterium and tritium, the figures 1 and 2 indicate that these isotopes contain one and two neutrons, respectively. The next row represents the helium nuclei; then the rows correspond to lithium, beryllium, boron and heavier nuclei.

The chart is presented in five sections. Throughout the chart the three numbers occurring in the squares correspond to the mass number, the abundance and the lifetime. In the second line zero appears for all nuclei that are not found in the elements as they occur in nature. In all but a few of the heaviest elements natural terrestrial sources always have the same isotopic abundances. This abundance is indicated by the figure in the second line. It should not be taken for granted that the isotopic abundance outside the earth is the same as on the earth. This, however, seems to be the general rule.

The figures on abundance are omitted in some of the heavy nuclei in which all isotopes are radioactive and in which the isotopic abundances are dependent upon the method by which the element is obtained.

The radioactive nuclei are distinguished in the chart, not only by the fact that in their squares a lifetime appears, but also by the arrows which indicate their process of decay. β-active nuclei are distinguished by arrows which point toward the upper left if negative electrons are emitted or by arrows in the opposite direction if positive electrons are emitted. Nuclei which do not have enough energy to emit an electron but capture an atomic electron are indicated in the same way as an ordinary positive electron emitter.

Some nuclei may decay both by positive and negative electron emission. This is indicated by two arrows attached to the squares. Alpha-activity of the nuclei is shown by an arrow in the lower left-hand direction and extending to the second diagonal neighbour. Thus in every case the arrow ends on the product of the radioactive decay.

The chart shows several interesting facts. Among the light nuclei only those with approximately equal numbers of neutrons and protons are stable. Those nuclei which have a great neutron excess are β-active and emit negative electrons, thus transforming a supernumerary neutron into a proton. Nuclei having too many protons emit a positive electron and transform a proton into a neutron. The fact that among light nuclei an equal number of neutrons and protons seems to give greatest stability to the nucleus is the result of the exclusion principle. The first neutrons and protons that build up a nucleus will occupy the lowest energy states. Each additional neutron and proton will be forced into an orbit of higher energy. If the number of neutrons greatly exceeds the number of protons, the last neutron will find itself in a state of rather high energy, while states of lower energy are still available for protons. Thus energy may be released by the transformation of a neutron into a proton. A similar argument holds for an excess of protons.

As the number of protons and neutrons becomes greater the stable nuclei tend to have a greater number of neutrons than protons. The reason for this is the electrostatic repulsion between protons. Because of this repulsion the presence of many protons in the nucleus causes an increase of the energy of the nucleus and transforming a proton into a neutron will correspondingly lower the energy. Too great a neutron excess will be prevented for the reasons discussed in the preceding paragraph.

It has been mentioned that the electrostatic repulsion in heavily charged nuclei gives rise to α-activity. The frequent occurrence of α-activity in the last elements of the chart can be readily observed. Instability of nuclei caused by the excess charge is probably the reason why fewer isotopes of heavy nuclei are known and why nuclei having more than 92 charge units do not occur in nature.

While two neutrons and two protons can never occupy exactly the same state within a nucleus, a pair of such particles may be found in the same orbit. These two particles must differ in the orientation of their spins. It seems that two particles in the same orbit possess similar energies. The result is that two successive particles can be bound in a low-energy state, while the addition of a third particle will release considerably less binding energy. This circumstance is illustrated by two facts in the chart of nuclei. First, few stable nuclei exist in which both the number of neutrons and the number of protons is odd. Such nuclei are usually radioactive, emitting a positive electron, a negative electron or both. The decay product is a nucleus in which both neutron and proton numbers are even and all orbits may be considered as doubly occupied.

The result of this rule is that nuclei with odd charge number Z possess many fewer isotopes than nuclei of even charge number. The other fact appearing from the chart is that in nuclei of even charge number the even isotopes, in which the number of neutrons is even, have a greater abundance than the odd isotopes, in which the number of neutrons is odd.

It seems that the latter nuclei, containing particles in less stable orbits, originally have been formed in smaller numbers than the isotopes having an even number of neutrons and greater binding energies.

Among the β-active nuclei two general rules may also be observed. First, that β-active nuclei which are located close to stable nuclei usually decay with a long lifetime. Nuclei which are located farther from stability have shorter decay periods. The other regularity is that radioactive nuclei containing even numbers of protons and neutrons have longer lives than nuclei containing an even number of neutrons and an odd number of protons or an even number of protons and an odd number of neutrons. These nuclei in turn live longer than nuclei in which both the proton and neutron numbers are odd. These regularities may be understood in terms of the energies of nuclei. In terms of β-decay it has been mentioned that the lifetime will be short if a great amount of energy is liberated in the β-decay. The lifetime will be long if the transformation energy is small. The transformation energy is apt to be less if the decaying nucleus has relatively low energy. This will be the case if the nucleus is near the region of stability and if the nucleus contains an even number of neutrons and protons. Closer inspection of the chart will show that the rules just mentioned are not universally valid and that there are quite a few exceptions. These exceptions occur whenever a β-decay of the anomalous type is encountered, in which case, as has been mentioned, β-active substances have a relatively long lifetime.

The abundances of isotopes show a further marked regularity. Among the light elements the heaviest isotopes are frequently

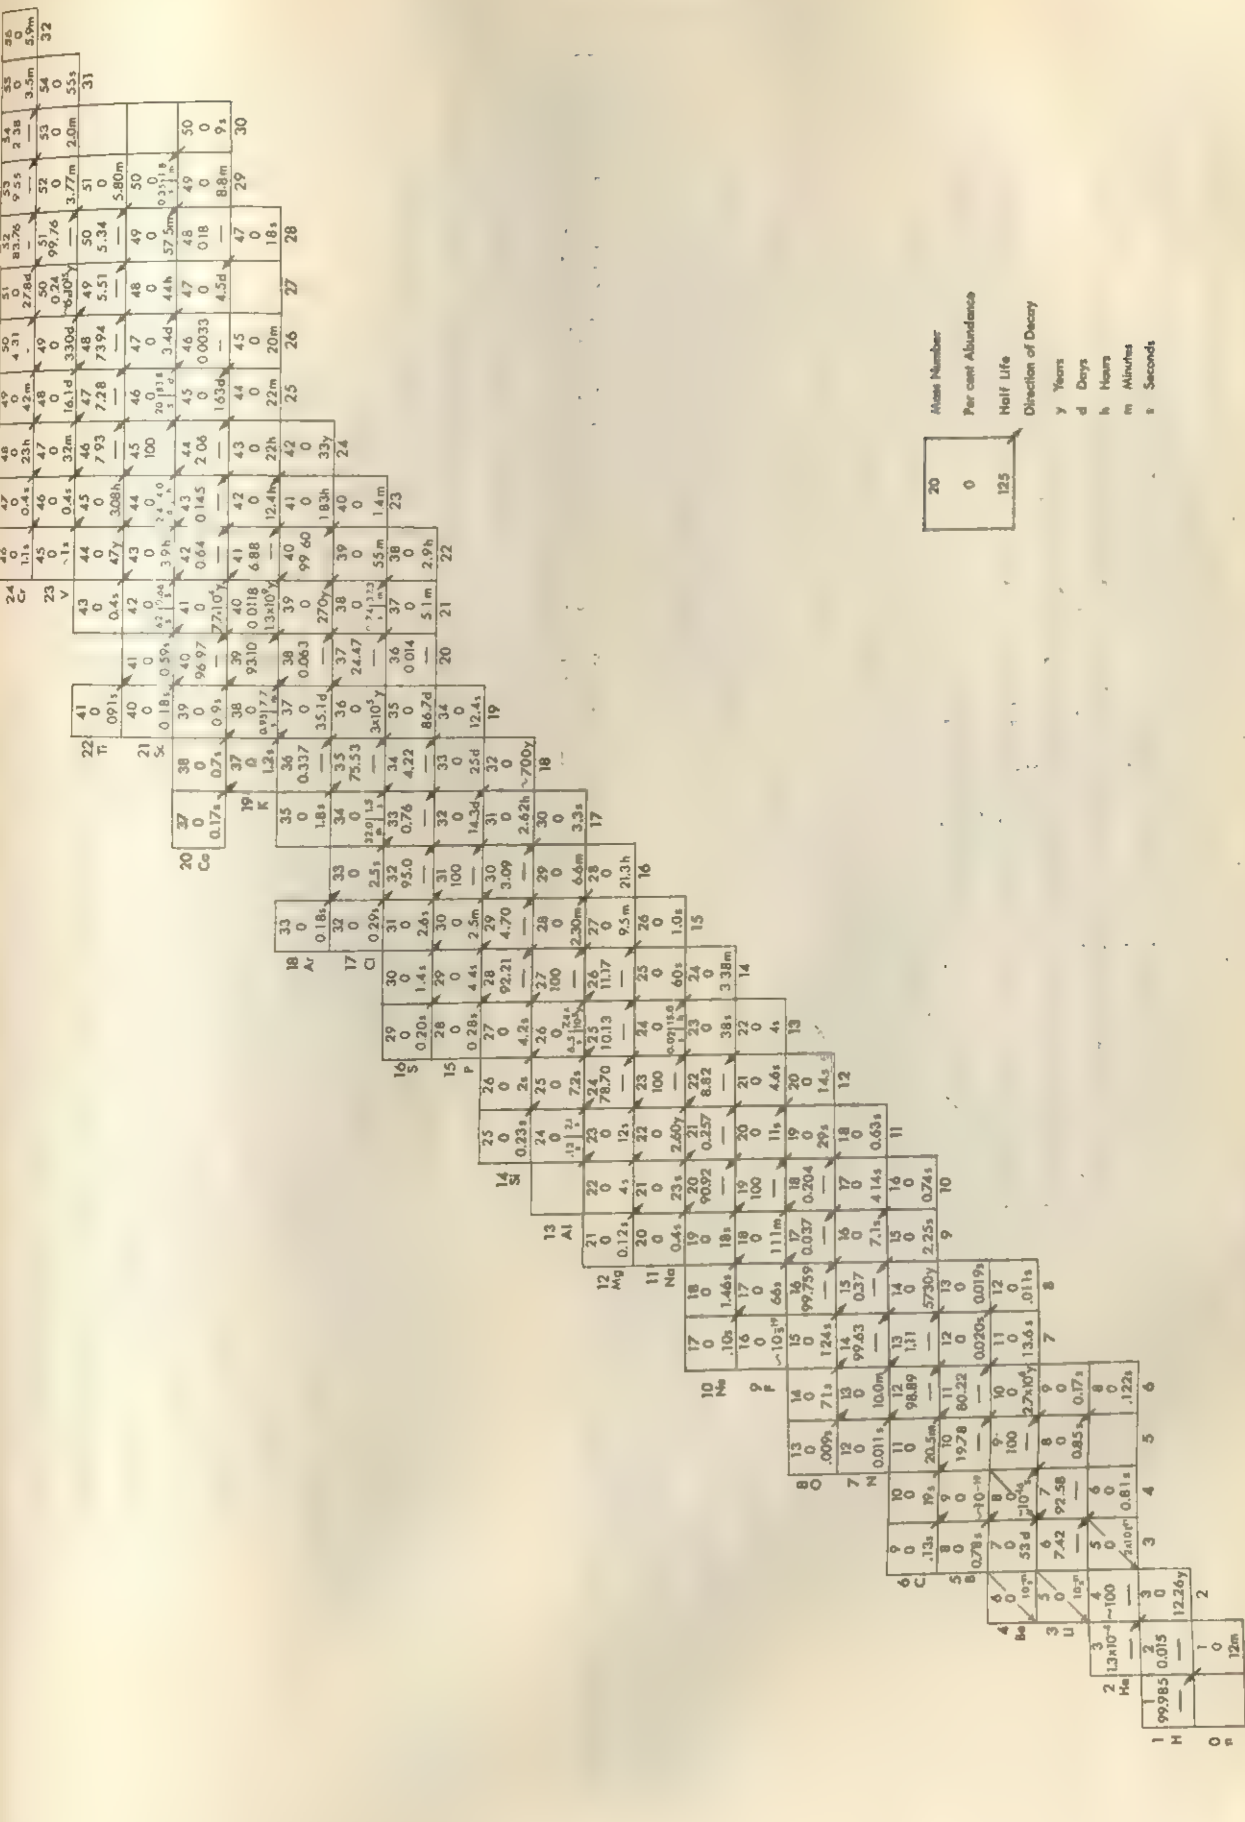

CHART OF PROPERTIES OF THE NUCLIDES

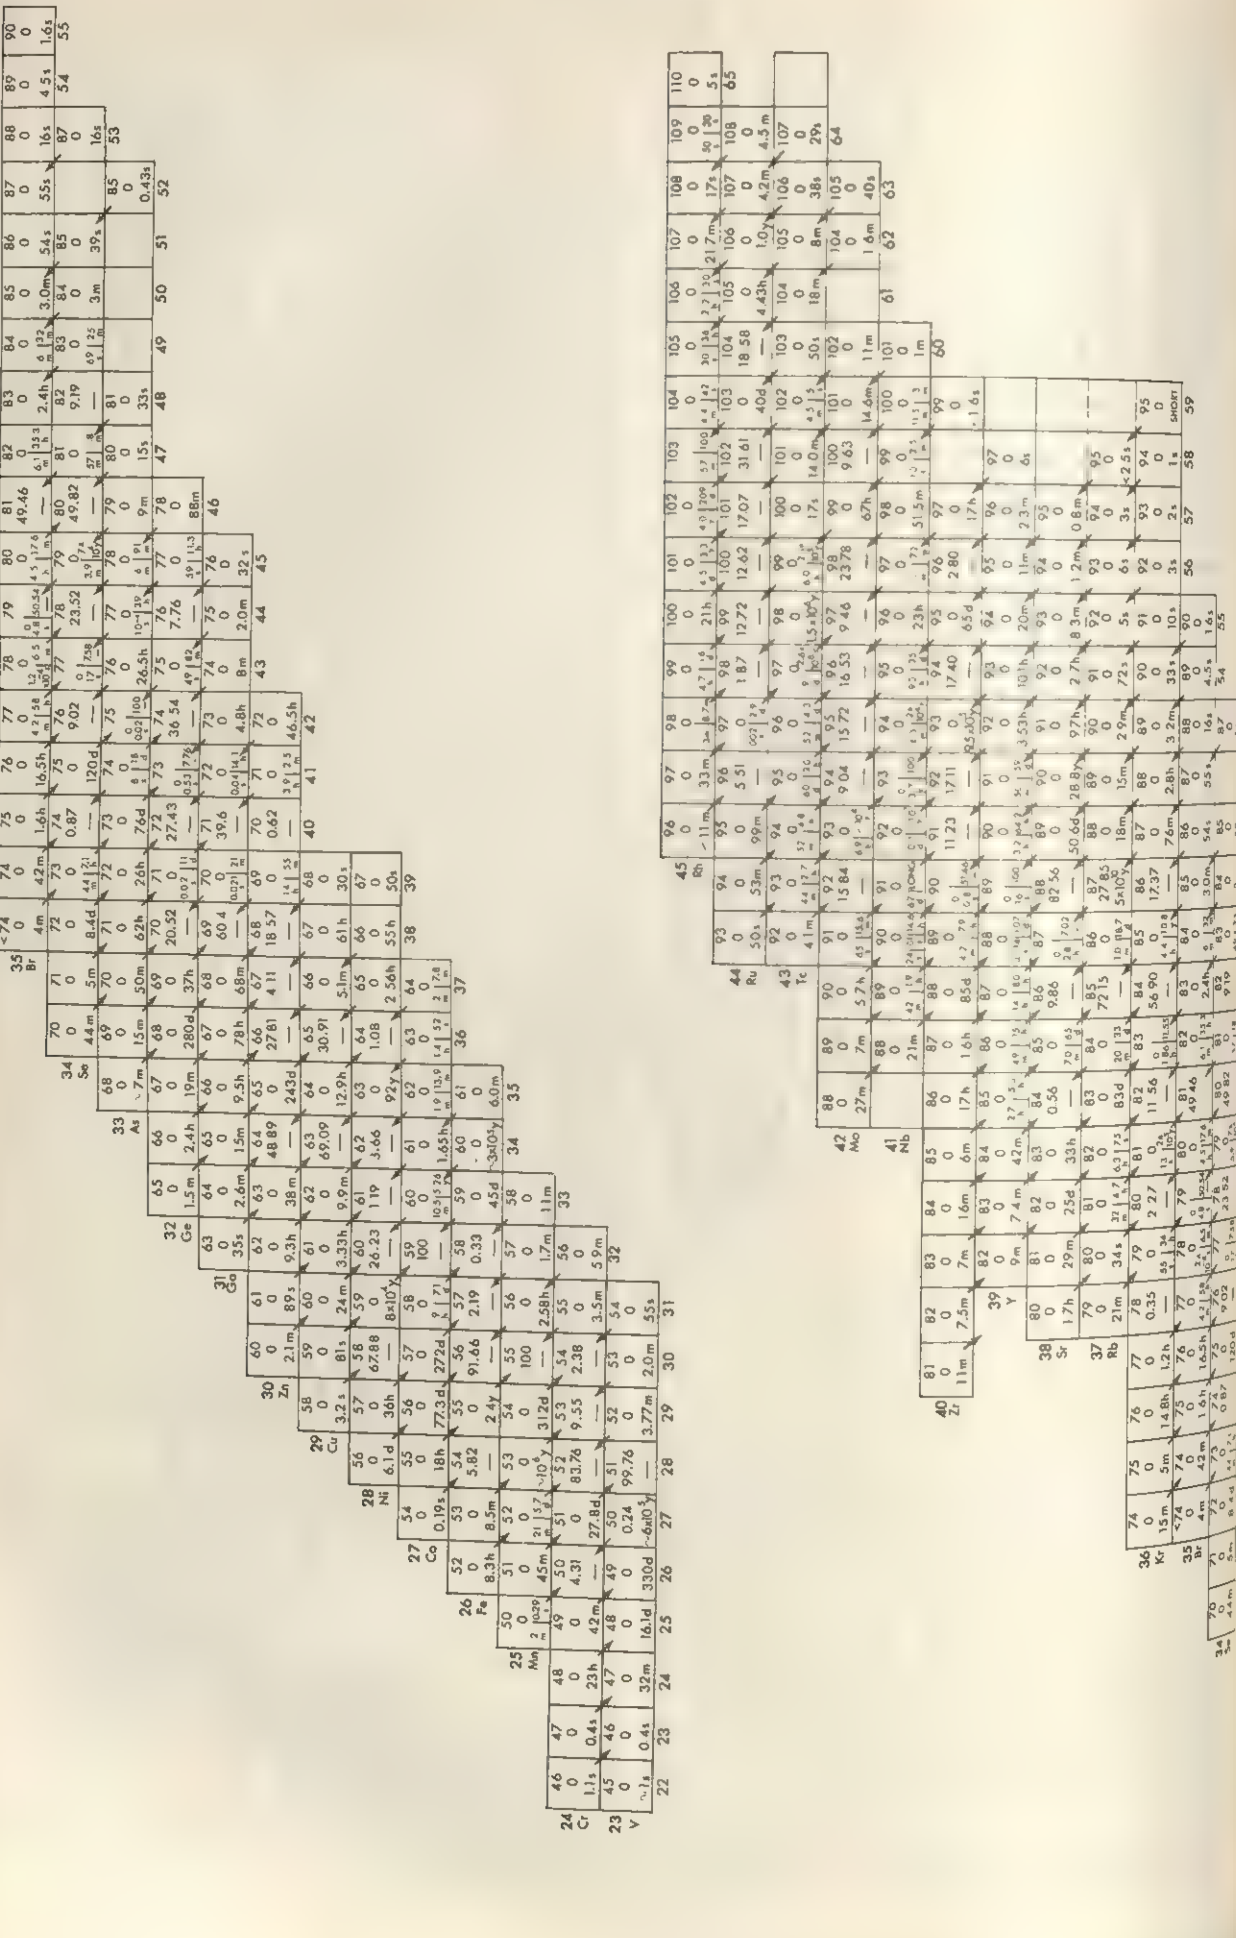

CHART OF PROPERTIES OF THE NUCLIDES—Continued

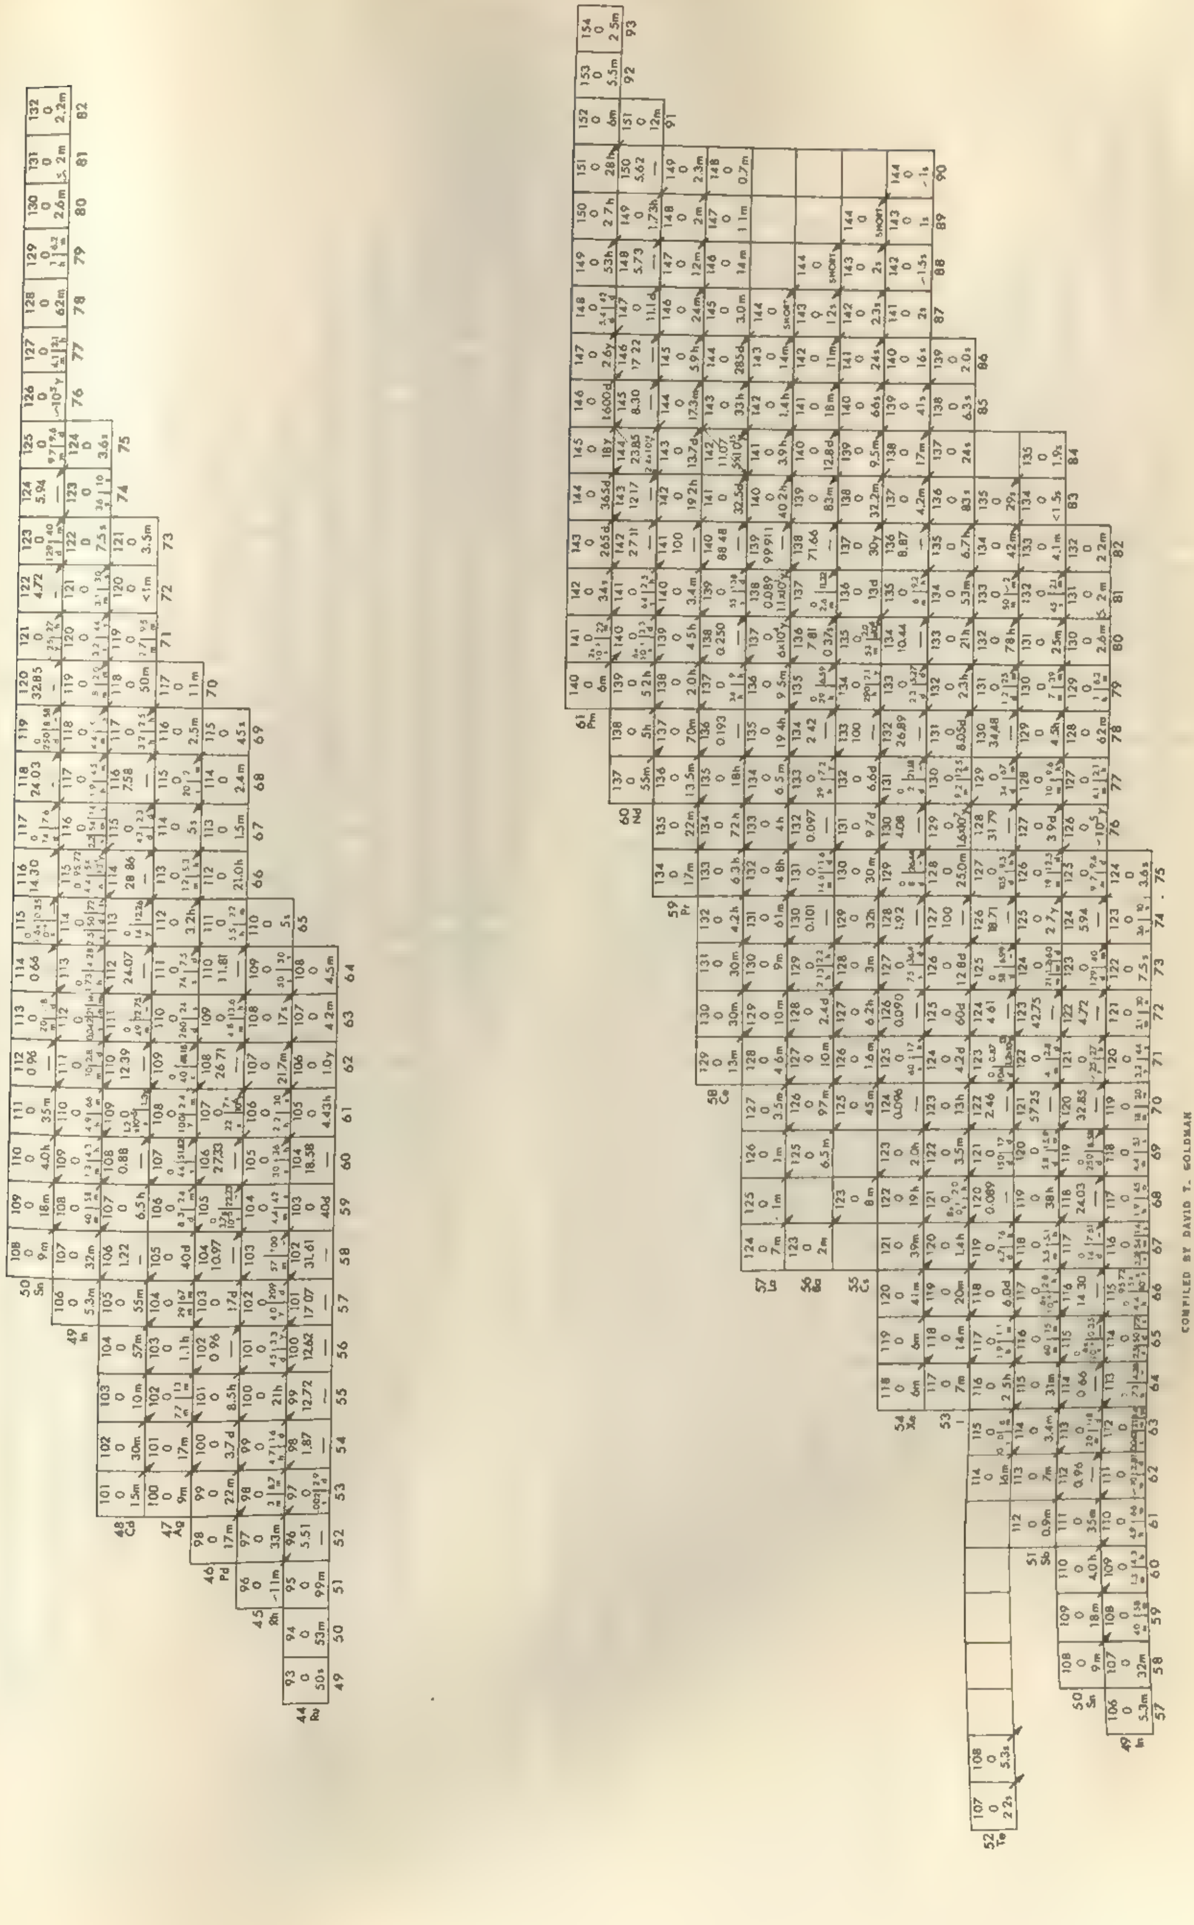
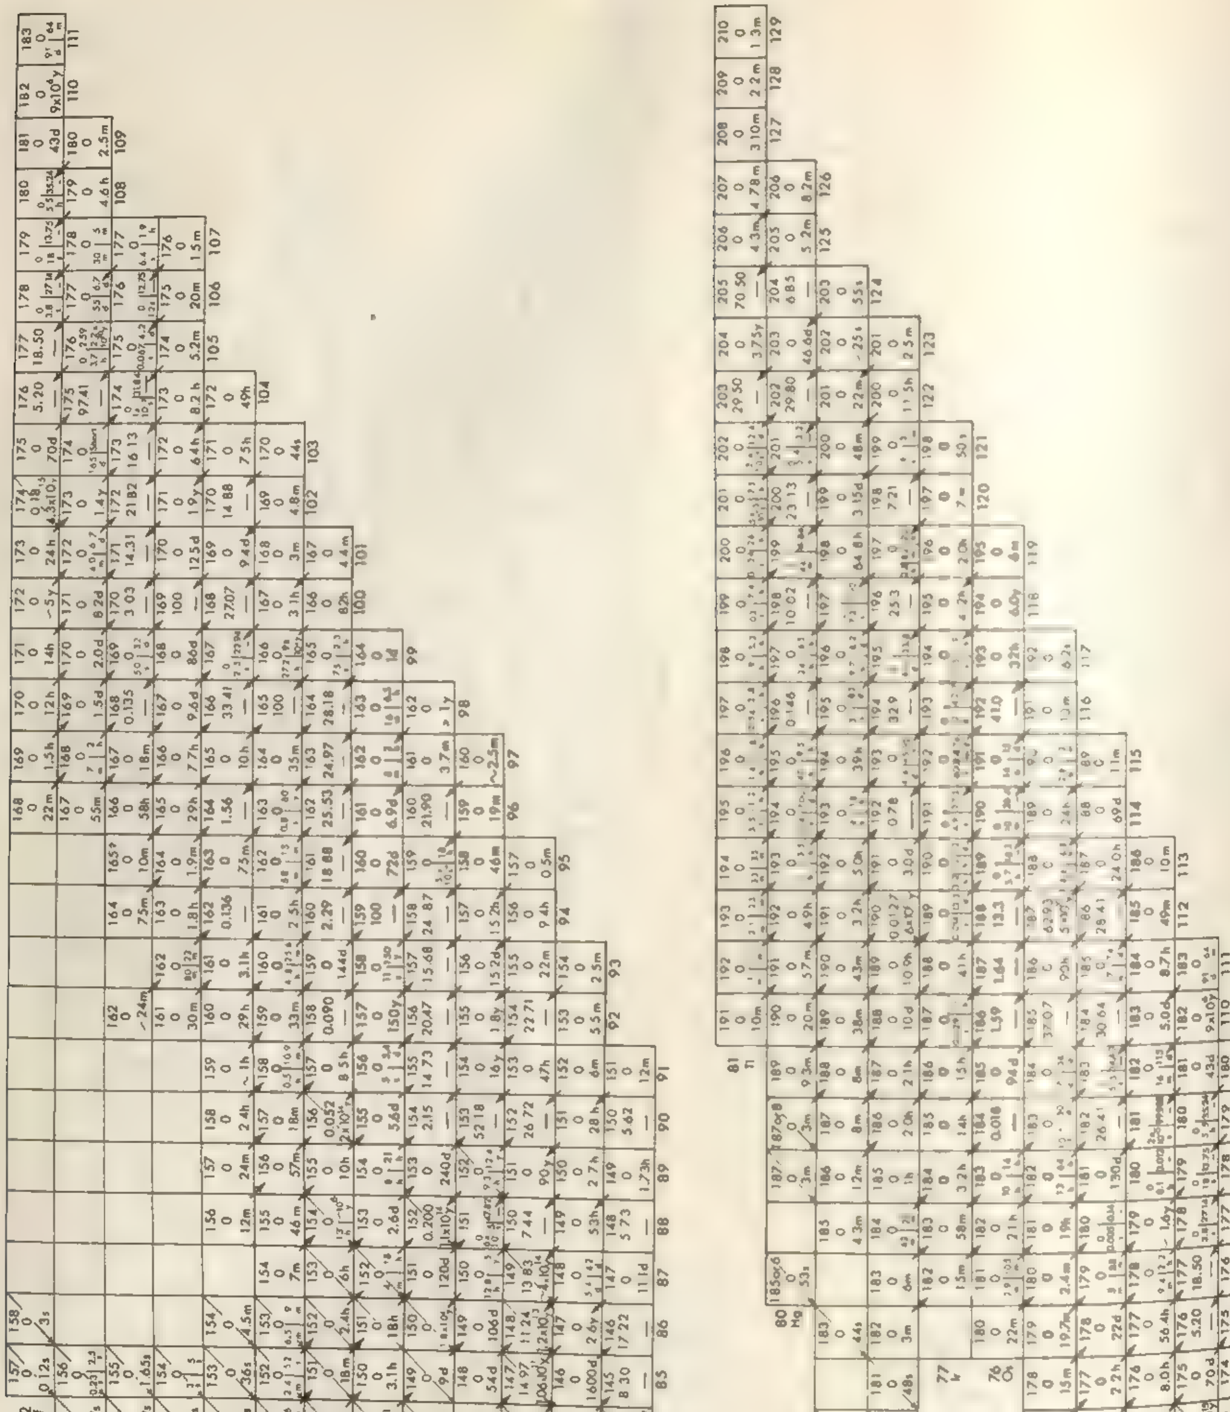
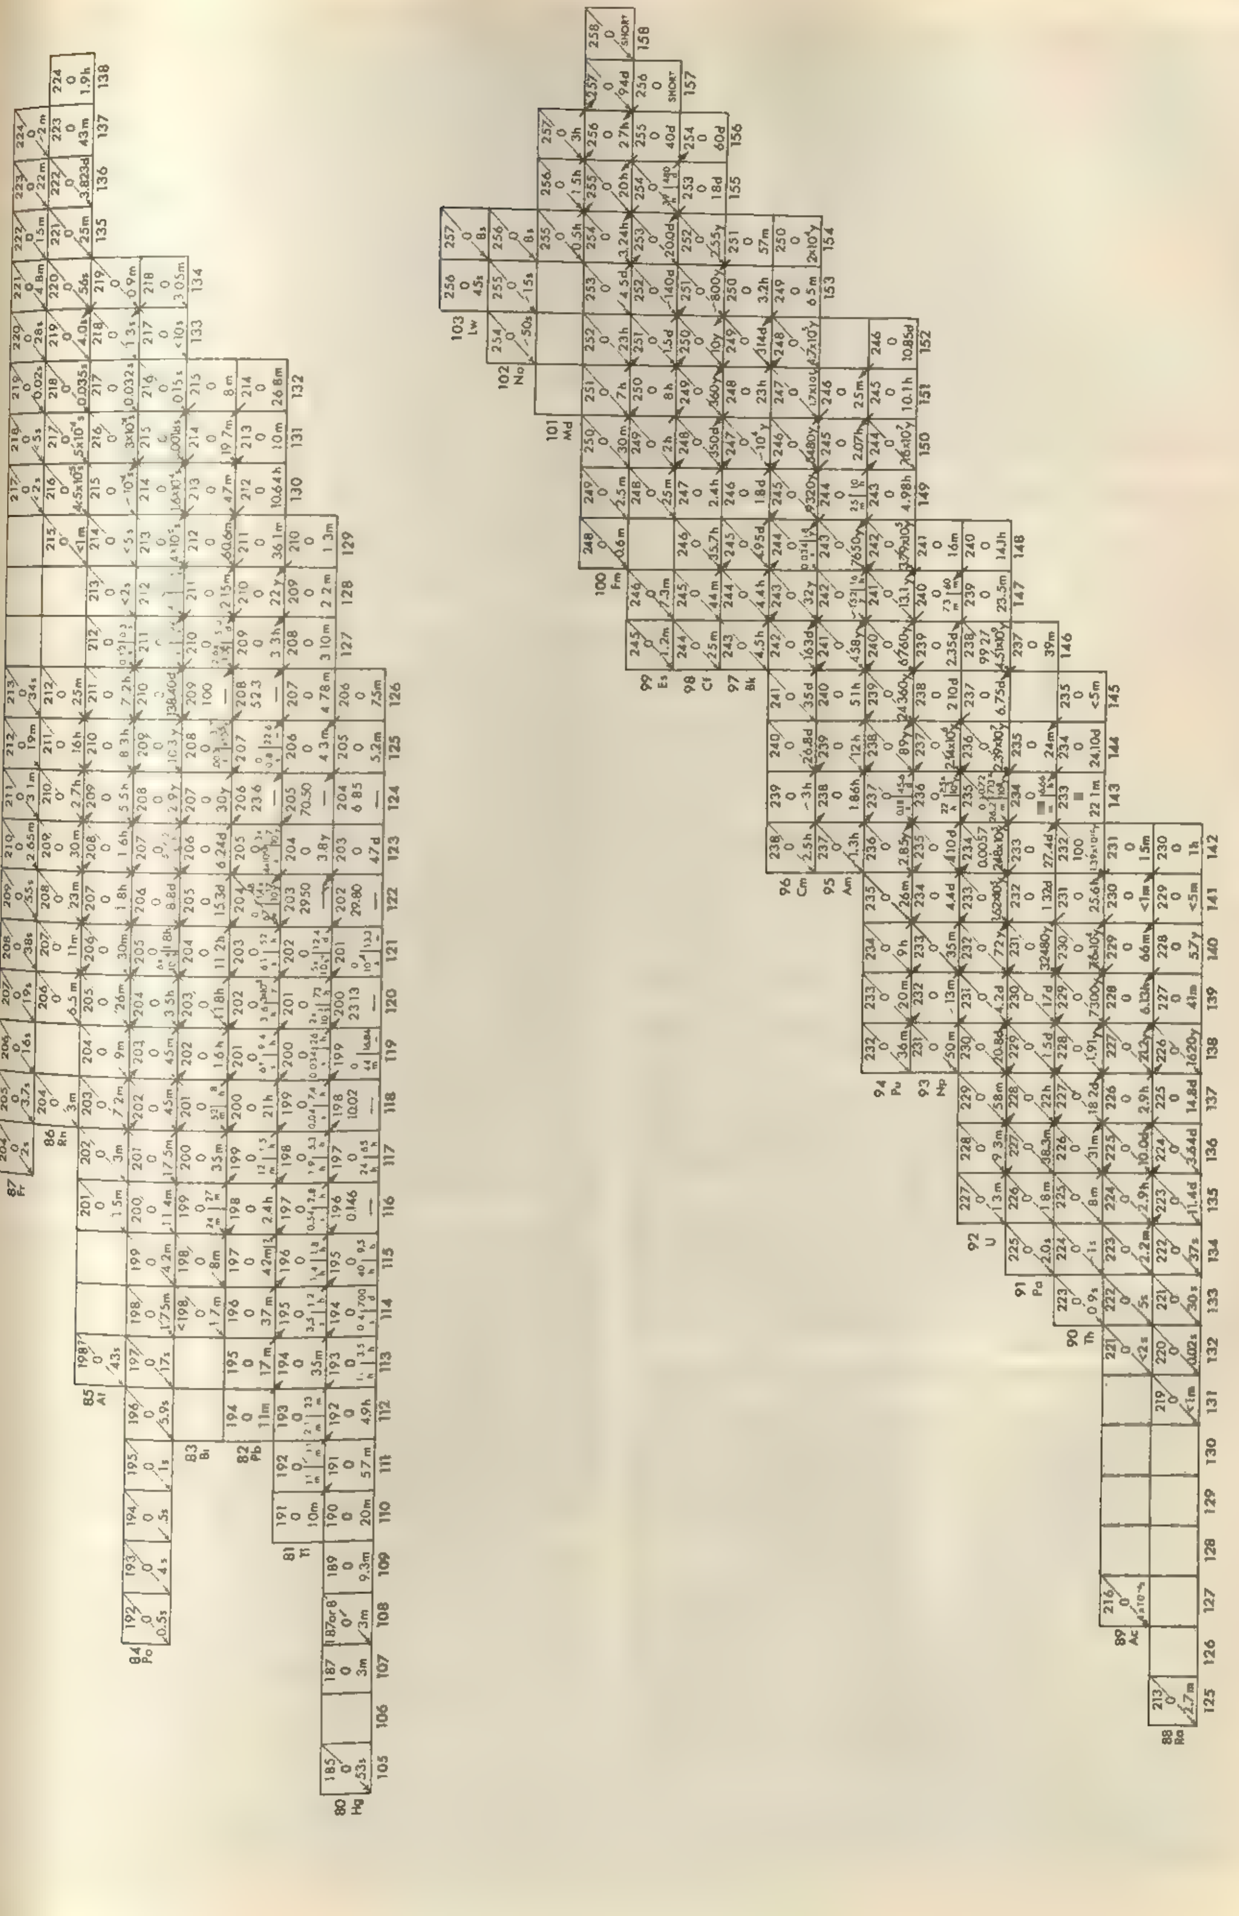


COMPILED BY DAVID T. GOLDMAN





COMPILED BY DAVID T. GOLDMAN

present in small abundance. Among the heavier elements the situation is reversed. It seems impossible to explain this fact on the basis of the stability of nuclei alone and it is likely that a hint is encountered here which may throw some light on the origin of the elements (*see* COSMOGONY: *Origin of Chemical Elements*).

In this connection it is also of great interest to compare the abundance of various elements. The determination of the abundance of elements is much more difficult than the measurement of the ratio of isotopic abundances. The reason for this is that while isotopic composition is remarkably constant, at least in terrestrial materials, the mixtures of various elements depend quite strongly on whence one obtains the mixture. Other elements will be found to predominate in the crust of the earth than in meteorites, which are believed to have a composition similar to the interior of the earth. A still different composition is found in the study of the sun. Even if we restrict ourselves to the earth's crust, a different result is obtained if igneous rocks are studied, sedimentary materials, the sea or the atmosphere. Fig. 4 gives the best available guess as to the abundance of various nuclear species through-

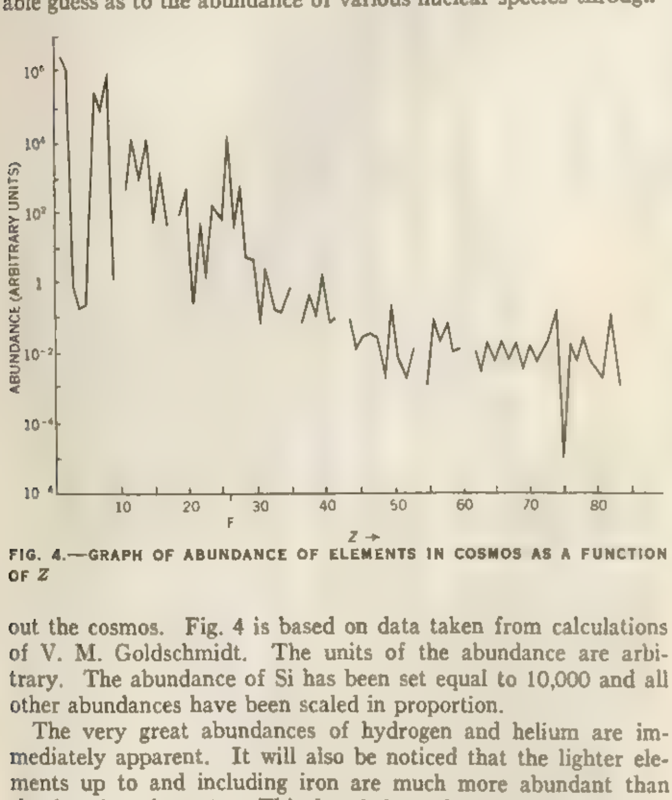


FIG. 4.—GRAPH OF ABUNDANCE OF ELEMENTS IN COSMOS AS A FUNCTION OF Z

out the cosmos. Fig. 4 is based on data taken from calculations of V. M. Goldschmidt. The units of the abundance are arbitrary. The abundance of Si has been set equal to 10,000 and all other abundances have been scaled in proportion.

The very great abundances of hydrogen and helium are immediately apparent. It will also be noticed that the lighter elements up to and including iron are much more abundant than the heavier elements. This has led to the suspicion that the lighter and heavier groups of elements have been formed by two basically different processes.

XI. NUCLEAR STRUCTURE AND NUCLEAR FORCES

The origin and nature of the nuclear forces are poorly understood. There is not even certainty that it is permissible to talk about forces within a nucleus in the customary sense of the word. Something is known, however, about the magnitude that forces between nuclear particles should have if these forces are to give rise to the effects that are observed (*see* FORCE).

A detailed theory of the interaction of slow neutrons with nuclei leads to the idea that there is very little interaction between the neutron and the nucleus until the neutron approaches to the distance of approximately one nuclear radius. At that distance the neutron is attracted to the nucleus with a strong force. The last statement is based on the fact that the union of a neutron with almost any nucleus releases a binding energy of several Mev. The facts so far described are summarized in the statement that the interaction between the neutron and other nuclear particles is a strong, short-range attraction.

If a proton approaches a nucleus the interaction at long distances is an electrostatic repulsion. By nuclear forces, of course, is meant the forces acting in addition to these electrostatic forces. As long as the proton is not in contact with the nucleus the effects of nuclear forces are considerably smaller than this electrostatic interaction. Attaching a proton to a nucleus releases a similar energy as when a neutron is attached. Thus, the interaction of the protons with other nuclear particles is again a strong, short-range attraction to which, of course, must be added the electrostatic repulsion, which acts over a greater distance.

Comparison of the binding energies of certain pairs of light nuclei leads to an important conclusion concerning nuclear forces. The first of these pairs is H^3 and He^3. The former consists of two neutrons and a proton, the latter of one neutron and two protons. The second known pair in the series is Li^7 and Be^7. The first is composed of three protons and four neutrons, the second contains four protons and three neutrons. The next pair is B^{11} and C^{11}, in which the numbers of protons and neutrons are five-six and six-five, respectively. In each of these pairs one member is obtained from the other if all neutrons are replaced by protons and all protons by neutrons. A large number of additional pairs of this type are known. For quite a few of these accurate determinations of the energy content of the nuclei are available. These energy contents differ because of the greater electrostatic repulsion prevailing in the nucleus which is more heavily charged than its partner. The remarkable fact is that the electrostatic repulsion is sufficient to explain the observed energy difference of the two nuclei in any of these pairs. We conclude that nuclear forces remain unchanged upon replacing all neutrons by protons and all protons by neutrons.

More detailed investigation of the behaviour of nuclei and also scattering experiments of protons on protons and neutrons on neutrons at various energies have led to a simple general rule. This is that neutrons and protons interact with each other in the same way as they interact with their own kind and that neutrons and protons are bound by the same forces within nuclei.

A detailed study of the proton-proton and neutron-neutron scattering at various energies has led to the conclusion that during such a scattering process the two interacting particles may exchange their charges. This exchange process gives rise to forces between the particles. It is likely, however, that these exchange forces account for only a portion of the total forces acting within nuclei. In spite of the similarity of the behaviour of neutrons and protons, the charge does therefore influence nuclear binding, but it does so in a similar way as the spin. Particles with different charge or different spin may occupy the same orbit, whereas particles with the same charge and spin may not. Furthermore, the exchange of charge and spin exerts an influence upon the nuclear forces.

It is instructive to consider what happens if the lightest nuclei are built up by adding one neutron or one proton at a time. The first combination, that of a neutron and a proton, has a relatively low binding energy of 2.2 Mev. A somewhat greater binding energy is released if a neutron or proton is added (the values are 6.2 Mev and 5.4 Mev, respectively). If a fourth particle is attached in such a way as to build a helium nucleus a very great amount of binding energy is released. The total binding energy of the two neutrons and two protons in the helium nucleus is 28 Mev. The great stability arising from this large binding energy accounts for the appearance of α-particles in radioactive decay. If we now try to attach an additional neutron or proton to the α-particle we find that the fifth particle will be bound very loosely. This will seem all the more remarkable if one considers that the α-particle is the only nucleus which fails to combine with a proton or a neutron. A glance at the chart of the previous section will show that the mass number 5 is associated with nuclei of extremely short life (about 10^{-21} sec. for He^5 and Li^5).

This situation is undoubtedly connected with the fact that according to the exclusion principle four and only four particles can be placed in the same orbit. Two particles in the same orbit must differ either in spin or charge or both. Now a nuclear particle can take two spin directions and two charge values (0 for neutrons and +1 for a proton). Thus the maximum number of particles in the same orbit is four and we must consider the He⁴

nucleus to consist of two neutrons with opposite spins and two protons with opposite spins. Since a fifth particle cannot differ by charge or spin from the four previous particles, the application of the exclusion principle indicates that the fifth particle must be accommodated in a new orbit. As a consequence, this particle will be more loosely bound and might, in fact, have a binding energy approaching zero. Properties of matter inside nuclei heavier than the helium nucleus have certain simple common characteristics. In particular, nuclear densities for these nuclei seem to be fairly constant so that the cube of the radius is proportional to the mass number A, that is to the number within the nucleus. The total binding energy of the nucleus is also proportional to this number so that the binding energy per nucleon is constant. This latter statement does not apply very well to the heaviest nuclei for which the binding energy per nucleon shows a marked decrease. This, however, is caused by the coulomb repulsions between the protons within the nucleus rather than by any intrinsic change in the characteristic behaviour of nuclear matter itself. The fact that the volume and binding energy per nucleon is roughly a constant for all nuclei beyond helium has been ascribed to a "saturation" of nuclear forces. Apparently in the helium nucleus the nucleons have achieved a nearly optimal density and binding energy.

Many of the detailed properties of the nuclei were explained by the nuclear shell model (M. G. Mayer, J. H. D. Jensen *et al.*, 1949). According to this model, individual nucleons are found in well-defined orbits within each nucleus. Each of these orbits is characterized by an orbital angular momentum, *i.e.*, a momentum around the centre of the nucleus; by a radial momentum, *i.e.*, a momentum away from and toward the centre of the nucleus; and a total angular momentum which is composed of the orbital angular momentum and the one-half unit spin momentum of the nucleon. Increasing angular momenta and radial momenta correspond to increasing energies. According to the Pauli exclusion principle, each orbit characterized by the appropriate momenta and by the spin may contain not more than one neutron and one proton. The orbits are filled in successively, those with lowest energy being filled first. The energies of these orbits can be calculated and one can therefore predict in which order the orbits of various characteristics will be filled up. One finds that a surprisingly low energy is encountered whenever an orbit has practically no radial momentum, that is, whenever the path of the nucleon can be considered as circular, provided that the angular momentum of the orbit and the angular momentum corresponding to the spin are lined up parallel to each other. There are several orbits of the kind just described which differ from each other by their orientation in the spherical field of the nucleus. When all these relatively low-lying orbits are filled up, one obtains a closed shell configuration and one arrives at a particularly stable nucleus.

The procedure mentioned above agrees with experiments particularly well for heavier nuclei. Application of these ideas shows that nuclei with unusual stability will result if the neutron number or the proton number happens to be either 50, 82 or 126. Stability of such nuclei was noticed before the explanation was given. The peculiar properties of the corresponding nuclei led to the designation of "magic numbers" for the numbers 50, 82 and 126. It is of interest particularly to mention the nucleus Pb^{208}, which is "doubly magic" since it contains 82 protons and 126 neutrons.

The nuclear shell model has been most useful in predicting angular momentum values for a great number of nuclear isotopes both in their lower state and in their excited state. The possibilities of β-decay and also the possibilities of emission of γ-rays are closely connected with these angular momenta. Therefore the shell model made it possible to obtain a consistent connection between β-decays, γ-ray emissions and detailed nuclear structure.

The explanation of nuclear structure by the shell model is similar to the explanation of the periodic system with the help of the shell model of the electrons within atoms. A quantitative difference exists, however, in that in atomic physics the difference between incomplete shells and closed shells is more marked than it is in nuclear physics.

The nuclear shell model suggests that nucleons can move across nuclei in a relatively undisturbed manner. Indeed, if that were not so, it would be hard to understand why well-defined orbits may be ascribed to individual nucleons. This conclusion is somewhat surprising since all nucleons undergo strong forces when entering or leaving a nucleus. We are therefore led to the following model of nuclear forces. When a nucleon approaches a nucleus, it is attracted into the interior of the nucleus and is therefore strongly accelerated. Inside the nucleus, the nucleon does not encounter any strong systematic change of the potential and is not exposed to any appreciable average force. It moves in this region almost as though the inside of the nucleus were free space. When leaving the nucleus, the nucleon will experience a strong retarding force, and will lose the kinetic energy which it acquired upon entering. The above discussion ignores the possibility of an energy loss the nucleon may suffer while traversing the nucleus but it gives a qualitative idea of the forces found inside a nucleus.

Further development of the nuclear shell model took place in the 1950s. It received a strong impetus from the discovery that nuclei with particles that are far from forming a closed shell configuration are strongly deformed, being ellipsoidal rather than spherical. These ellipsoidal nuclei have a number of properties that are quite analogous to those of diatomic molecules. In particular, they have energy levels, arising from their rotational motion, that are spaced proportionally to the numbers 1, 2, 3, 4, ... It is found that these rotational states can easily be excited by permitting charged particles to collide with the nucleus, a process called Coulomb excitation. Attempts to improve the shell model to include a description of these phenomena (unified model of A. Bohr and B. R. Mottelson) had a considerable success and the resulting predictions inspired a number of fruitful experiments.

The nature of nuclear forces cannot be understood unless one considers both the field in a quiescent nucleus and that in a nuclear structure whose components undergo violent motion and acceleration. The situation may be clarified by a comparison with the electric forces that confine the electrons to their orbits within the atoms. These forces actually have two manifestations. On the one hand, they influence the orbits of the electrons. On the other hand, they give rise to electromagnetic radiation. The latter phenomenon occurs when the electric configuration within an atom suffers a sudden change and part of the electric field in the neighbourhood of the atom is shaken loose.

The situation is similar in the case of nuclear forces. On the one hand, they confine nucleons to their orbits. On the other hand, one has to expect that if a nucleus is subject to sudden and violent change, a peculiar nuclear radiation will be emitted. This nuclear radiation has been identified with at least some of the mesons which have been described above.

The nuclear radiations (that is, the mesons) differ in two basic respects from electromagnetic radiation. The first difference is that electromagnetic radiation may carry an arbitrarily small amount of energy. A meson, on the other hand, cannot carry an energy less than a certain given minimum amount. A mass corresponds to this minimum energy according to Einstein's relation of equivalence of mass and energy. For the π mesons, which have been most closely identified with nuclear radiation, this mass is approximately 270 times greater than the mass of the electron and is roughly one-seventh of the mass of a nucleon. The fact that the nuclear radiation has a minimum energy is connected with the short range of nuclear forces. As a result of this short range the time of vibration of nuclear radiation will necessarily be shorter than a certain minimum time. According to the mechanics of atomic systems, short times are necessarily connected with high energies. The existence of the mesons as a form of nuclear radiation was first postulated by H. Yukawa. These mesons were then found in cosmic radiation (*see* COSMIC RAYS) and later in nuclear reactions; they possessed the qualitative features that had been predicted.

The second important difference between electromagnetic radiation and nuclear radiation as represented by mesons is connected with the electric charge carried by the radiation. Electric radi-

ation does not carry a charge; many mesons do. The π mesons which are known to be connected with nuclear forces appear in three forms: the neutral π mesons, the positive π mesons which carry one positive unit of electricity and the negative π mesons which carry a negative unit. In their interaction with nuclear matter these three kinds of π mesons behave quite similarly. This fact is connected with the rule mentioned above that nuclear forces act similarly on protons and neutrons. The spin of the π mesons is known to be zero, that is, they do not carry an intrinsic angular momentum. Their mathematical description, however, exhibits a peculiar behaviour with respect to mirror reflections. It is a consequence of this peculiar property that emission of a π meson does not in itself cause a change in the angular momentum of the emitting nucleon but it is likely to cause an exchange of angular momentum between the spin and the orbit of the nucleon.

Many other kinds of mesons have been observed and some of these may well be connected with nuclear forces in a manner similar to the connection existing in the case of the π mesons. It will be, however, clear even to the most superficial observer that present hypotheses concerning nuclear forces have been introduced piecemeal, seem to consist of several independent statements and do not proceed by a cogent reasoning from a number of simple hypotheses. These are the marks of an unfinished theory. A more nearly complete explanation will probably contain unexpected elements and will probably form a more closed and simple pattern than the present disconnected set of assumptions.

XII. ENERGY PRODUCTION IN STARS

The energy source responsible for the radiation of the sun and stars was the subject of speculation for many years. It was recognized long ago that no known chemical reaction could keep the sun supplied with energy for more than approximately 100,000 years. Yet there is geological evidence that the sun must have been radiating at its present rate for 500,000,000 years; *i.e.*, during the period in which living beings seem certain to have inhabited the earth. More recent detailed theories of the interior of the stars did not lead to any suggestions as to some novel kind of chemical reaction (some kind of rearrangement of atoms or extranuclear electrons) which could account for the extremely great amounts of energy that the sun has emitted during its long history.

Somewhat more energy could be obtained from a slow gravitational contraction of the sun. It is not easy to construct a model of the sun (or stars), however, which would permit the sun to radiate at its present rate for more than a few million years without considerable change if gravitational energy were the main source of the energy radiated. Actually, a great concentration of mass near the centre of the sun could give rise to sufficiently high gravitational energies and a slow growth of this very dense core could account for the energy emission of the sun. In order to obtain the necessary energies one would have to assume near the centre of the sun densities of matter which are approximately 10^{12} times greater than the densities of water. Such high densities had been encountered only in the interior of nuclei.

It seems, therefore, most likely that the energy of the sun and stars results from nuclear transformations. The theory of the structure of the sun and stars has led to the conclusions that the central regions of these bodies are at temperatures approximately 20,000,000° to 50,000,000° F. At these exceedingly high temperatures atomic nuclei move with sufficiently high velocities so that occasionally they come in close contact and give rise to a nuclear reaction. Actually the average energy of atomic nuclei inside the sun is only 2,000 or 3,000 ev. This energy is rather low compared with the energies usually encountered in nuclear reactions. If the kinetic energy in the sun were as high as the kinetic energy of protons or α-particles which are used in the laboratory to produce reactions, then nuclear reactions on the sun would probably go to completion in a very short time and the sun would explode, rather than produce energy at a steady rate. The small kinetic energy of nuclei in the sun has the consequence that nuclear reactions take many times 1,000,000,000 years to go to completion (*see* SUN).

It is, of course, of interest to find out which specific nuclear reactions supply the energy of the sun. While there are numerous reactions which might, in principle, be considered, practically all of them were eliminated as the actual source. Some reactions would proceed too rapidly and result in burning up the nuclear fuel too quickly. Other reactions, in which heavily charged nuclei participate, proceed so slowly that they could not produce sufficient energy. In 1937 H. Bethe and others discussed this question and arrived at the conclusion that there are two series of reactions which jointly or separately may explain the behaviour of the sun and the stars. One of these series is the following: a proton collides with a C^{12} nucleus and is captured; the capture process is accompanied by the emission of γ-rays; the resulting N^{13} nucleus is β-active and transforms into C^{13}; a second proton collides with the C^{13} nucleus and is captured, again emitting γ-rays; by this process a stable N^{14} nucleus is formed; the latter captures a proton, emitting the capture energy as γ-rays; an O^{15} nucleus results; this nucleus is β-active and transforms to N^{15}; finally a collision of a proton and N^{15} gives rise to C^{12} and an α-particle. This series of reactions can be summarized in the following formulas:

$$C^{12}+H^1 \rightarrow N^{13}+\gamma$$
$$N^{13} \rightarrow C^{13}+e^+$$
$$C^{13}+H^1 \rightarrow N^{14}+\gamma$$
$$N^{14}+H^1 \rightarrow O^{15}+\gamma$$
$$O^{15} \rightarrow N^{15}+e^+$$
$$N^{15}+H^1 \rightarrow C^{12}+\alpha$$

It will be noted that as a result of the series four hydrogen nuclei have disappeared and one helium nucleus (α) has been formed. The original C^{12} nucleus has been reproduced at the end of the reactions. Apart from the energy released in γ-rays and kinetic energy, the net reaction can be written:

$$4H^1 \rightarrow He^4+2e^+$$

Indeed, hydrogen and helium seem to be the most abundant constituents of the sun. We have seen in earlier discussions that the building up of the helium nucleus releases more energy per unit mass than any other type of nuclear reaction. Thus the proposed mechanism employs the most abundant materials in the sun in the most effective manner.

The other series of reactions is the following:

$$H^1+H^1 \rightarrow H^2+e^+$$
$$H^2+H^1 \rightarrow He^3+\gamma$$
$$He^3+He^3 \rightarrow He^4+H^1+H^1$$

The net result is the same as in the previous series, namely the transformation of four protons and two electrons into a helium nucleus.

XIII. UTILIZATION OF NUCLEAR ENERGY

The release of nuclear energy for practical purposes may be classified as controlled or explosive. Both historically and technically the two aspects are closely connected. Nuclear explosives were a key factor in the great armaments race among the major powers which began at the end of World War II. Consequently, a full account of all important developments was often available to the general public only a considerable time after they occurred. Quantitative information was in general withheld if it had any bearing on the design of weapons. However, by the time of the Geneva Conference on the Peaceful Uses of Atomic Energy in 1955, the essential information then available on the nonexplosive release of energy by fission had been published. The processes involved may be described as follows.

If a uranium or thorium nucleus is hit by a neutron of appropriate energy nuclear fission results with considerable probability (*see* section on nuclear reactions). The two approximately equal fragments into which the nucleus separates carry a total energy of almost 200 Mev in the form of kinetic energy. Some of the energy released is present as internal energy of the fragments and a part of this internal energy splits neutrons off these fragments.

As a result of each fission process a few neutrons are obtained in addition to the fission fragments. These neutrons can enter other heavy nuclei; they cause fission and give rise to more neutrons. In each one of the steps the neutrons are multiplied. This results in a rapid increase in the total number of fissions and leads

within a short time, to a number of neutrons and a number of fissions comparable with the number of nuclei in the available material.

The multiplication of neutrons and the corresponding multiplication of fission processes is called a chain reaction. This repeatedly branching chain of reactions makes it possible that starting with a few neutrons one may end with so great a number that a substantial fraction of the myriads of nuclei is eventually involved in the process.

The simple type of chain reaction described here explains the functioning of the atomic bomb. When this reaction is initiated in an appropriate piece of material, energy is released so rapidly that a violent explosion results. In explosions carried out so far the energy released is equivalent to that produced by many thousands of tons of T.N.T. Fortunately none of the materials occurring in nature is capable of supporting a simple chain reaction that would give rise to an "atom bomb" type of explosion. In both thorium and ordinary uranium an additional reaction exists which competes with the fission process and renders the process harmless. This competing process is the absorption of a neutron in thorium or U^{238} according to the reactions:

$$Th^{232}+n \rightarrow Th^{233}+\gamma$$
$$U^{238}+n \rightarrow U^{239}+\gamma$$

In order to produce atomic bombs materials are needed in which competing processes do not occur. Such a material is U^{235}, an isotope which occurs in the natural mixture of uranium with an abundance of 0.7%. Separation of this isotope from naturally occurring uranium was carried out on a large scale in the United States during World War II.

Another material which can support a simple chain reaction and which can be used in atomic bombs is Pu^{239}. Plutonium is an element which carries two more charges than uranium and is the first element that has been artificially made and handled in considerable quantity. Plutonium is obtained from the abundant isotope of uranium, U^{238}. As mentioned above, neutron bombardment transforms this element to U^{239}. This material by two successive β-decay processes becomes Pu^{239}. The latter material was also produced in the United States during World War II.

Energy of the fissionable materials may also be released in a steady manner without any explosion. In order to accomplish this, the energy released in the fission processes must be removed by heat conduction. The energy which has been conducted can then be utilized as a source of power. The excess neutrons created in the fission process must also be absorbed so that instead of a multiplying chain reaction there is a chain reaction in a steady, self-sustaining state. In the process of neutron absorption artificial radioactive products frequently are generated which can be used in research and for medical purposes.

Up to the mid-1960s the use of nuclear reactors in producing materials for research had been perhaps of greatest importance. This usefulness is due to the fact that a radioactive atom has precisely the same chemical behaviour as its known radioactive counterparts or isotopes. Thus a radioactive carbon or sulfur atom will behave precisely in the same way as a normal carbon or sulfur atom. Because of its activity, however, it can be easily discovered in the most minute quantities. Thus, one can trace the path of substances introduced into a living system or into a piece of machinery throughout its passage and incorporation in the system.

There is no difficulty in constructing a reactor in which the neutron population remains steady. In order to accomplish this, the neutrons produced in fission must be disposed of either by absorbing them in other nuclei or by allowing them to escape through the surface of the system. In every case one will construct the chain-reacting system in such a way that the ratio between neutron loss and neutron gain can be regulated. The regulation can be achieved by lowering into the reactor a neutron-absorbing substance such as a rod containing boron. Neutrons are then consumed in the reaction

$$B^{10}+n \rightarrow Li^{7}+He^{4}$$

When the system starts to operate there are only a few neutrons around, produced by the cosmic rays or other sources. The neutron-absorbing substance is then withdrawn so that the neutron loss becomes less than the gain of neutrons caused by fissions. The neutrons start to multiply and soon the neutron density and the rate of fission reaches the level at which the system is to be operated. At this time the neutron-absorbing rod is reinserted to an extent that neutron absorption and neutron production are just equal. When the operation of the system is to be shut off, the neutron-absorbing substance is pushed in farther so that the neutron loss exceeds neutron production. The number of neutrons then decreases to the small value that it had originally.

The rate at which such a system releases energy is proportional to the neutron density. The density, in turn, may be regulated at will by choosing the instant at which the neutron-absorbing material is reinserted into the pile and the increase in neutron density is stopped. From a practical point of view the rate of energy release is limited, however, because it is possible to carry out of the system a limited amount of energy in the form of heat. If more energy is produced than can be carried away, this results in an increased temperature of the entire system. As a consequence the system may shut itself off or, failing to do this, may blow up. The main problem to be solved is, therefore, not the production of energy but its control and utilization.

The regulation of the level at which the neutron density is to be kept is greatly facilitated by the fact that some of the neutrons are produced in the fission process with some delay. The delay results from the fact that some fragments of fission undergo a β-decay before they emit a neutron. The lifetime of such a β-decay process ranges from a second to a minute and neutrons are emitted with delays of corresponding duration. These delayed neutrons are utilized in operating the chain-reacting system. The system is operated under such conditions that the neutrons produced instantaneously in the process are slightly fewer than the neutrons absorbed or otherwise lost in the system. Under the circumstances the reacting system always has to wait for these delayed neutrons for effective neutron multiplication to take place. The multiplication of neutrons is thus slowed down and there is plenty of time to adjust the neutron-absorbing material when the neutron density and energy production approach the desired values, or when there is an excessive increase in power production.

It is possible to construct chain-reacting systems of rather small extension and small weight. Nevertheless, there are serious problems in the practical use of such energy sources, although their lightness and power are highly desirable in aircraft. The reason is that the fission process and also later nuclear processes accompanying it emit considerable amounts of radiation in the form of neutrons, β-rays and γ-rays. If these were allowed to escape everyone who approached the chain-reacting machine would be killed. The system must be surrounded with an absorbing shield that is thick enough to reduce these dangerous radiations to an exceedingly small fraction of their original intensity. To achieve this purpose the shield must be heavy. This sets a severe limitation on the use of nuclear energy in machines that are small and easily moved. Despite these problems, nuclear aircraft were under development in the U.S. during the 1960s. While the apparatus that produces energy is of necessity both heavy and bulky, once it is set up it can function for a long time without being supplied with additional nuclear fuel. In the long run added fuel is needed but the weight of the raw material is completely negligible compared with the weight of coal or fuel oil needed for the same energy production. Thus nuclear power plants are independent of heavy fossil fuels. At the same time they can be more easily constructed than hydroelectric plants. Thus by the mid-1960s useful electric power was being produced by stationary nuclear reactors in the U.K., U.S.S.R. and U.S.; the latter two countries were operating nuclear-powered ships, including submarines and other vessels for commercial use.

The nuclear materials that can be most easily used in constructing nuclear power plants are the same as those needed for the atomic bomb. They are the materials in which nuclear fission occurs with greatest ease without too many competing processes that absorb neutrons. It is also possible to build a nuclear power plant using only common uranium, a substance which cannot be

used in atomic bombs. The reason is that ordinary metallic uranium cannot sustain a nuclear chain reaction because more neutrons are absorbed in the isotope U^{238} than are produced by fissions in both isotopes. Neutron multiplication can be obtained if some appropriate material, such as carbon, is added to the system. The neutrons produced in fission are slowed down by repeated collisions with carbon nuclei. Finally the neutrons are transformed into thermal neutrons and the slowing-down process ends. The U^{235} reacts preferentially with these slowed-down neutrons. In spite of the fact that U^{235} is present in the normal isotopic mixture to an extent of 0.7%, successful collisions between slow neutrons and U^{235} become frequent enough to give rise to a sufficient number of fissions and an excess of neutron production. The processes described need only common materials like uranium and carbon, but the neutron excess obtained in this way is small and losses must be carefully avoided. Such neutron losses always occur at the surface of the chain-reacting system. These surface losses can be reduced by making the machine bulky (*see* NUCLEAR ENGINEERING).

If a chain-reacting system is built up from ordinary uranium many of the neutrons produced are absorbed in the abundant U^{238}. The resulting U^{239} decays into Pu^{239}, a material which is usable in more convenient plants and also in atomic bombs. It should be noticed that every process of useful atomic energy production is closely connected with the destructive use which can be made of this great energy source.

In contrast with the situation for the release of energy by fission, information on the energy release by fusion was not fully available in the 1960s. The very existence of systematic attempts to make hydrogen bombs in the U.S. was not public knowledge until late 1949. In early 1950, Pres. Harry S. Truman ordered a full-scale attack on the problem. The exceedingly high temperatures necessary for the thermonuclear reactions made laboratory experiments difficult. The most readily available method for producing such temperatures was to explode an ordinary fission bomb. This was done in the tests in the spring of 1951. The resulting measurement of the rates of reaction together with intensive theoretical work and some imaginative innovations of design made possible actual tests of weapons in 1952 and later. A test of an apparently similar type of weapon was reported in the U.S.S.R. in 1953, and a British hydrogen bomb test was performed in 1957. There are two features of these weapons which have received considerable public attention. The first is their great energy release: they are rated as megaton weapons; *i.e.*, equivalent to several millions of tons of TNT on a scale such that the first atomic bombs exploded over Japan were 20,000-ton weapons. The second is the very large quantity of fission-product radioactivity they release.

The existence of systematic attempts by the U.S. and Great Britain to produce controlled thermonuclear reactions on earth was first announced at the Geneva conference in 1955. The problem is difficult because the extraordinarily high temperatures required make it hard to confine the reaction to a region of space. Efforts were being made in the 1960s to confine such fusion reactions in magnetic fields (*see* MAGNETOHYDRODYNAMICS).

XIV. HIGH-ENERGY EXPERIMENTS ON NUCLEI

The construction of a variety of high-energy particle accelerators and improvement in particle detection techniques in the decade after 1945 made possible a number of important experiments.

The primary purpose of many of the experiments was the search for new elementary particles and the systematic study of their properties. Once the characteristics of the new particles had been established, the experiments often could give information on nuclear structure. The study of π and μ mesons illustrates this situation. When a negative π or μ meson is slowed down in solid matter, it usually will form a mesic atom. Such atoms have nuclei like those of ordinary atoms, but a negative meson moves on a Bohr orbit around the nucleus. The orbits of the meson are smaller in size than the corresponding electron orbits by the ratio of the electron to meson mass and their binding energy is larger by the inverse of that ratio. Just as in ordinary atoms, a transition from one Bohr orbit to another results in the emission of a photon. (In heavy elements and for the larger Bohr orbits photon emission by the meson is less probable than the Auger effect, in which the energy released by the transition is transferred not to a photon but to one of the electrons of the mesic atom.) Because of the higher binding energy of mesons, the most energetic photons emitted by π and μ mesons in light atoms such as carbon and beryllium are X-rays rather than visible light. In the case of the π meson, these mesic X-rays can be measured accurately by comparing them with X-rays emitted in electron transition in medium heavy elements. Such measurements led to a precise determination of the π meson energy level separations, and indirectly to a very accurate measurement of the π meson mass. In fact, the measurements were so precise that it was possible to detect small deviations from Coulomb's law for the electric force between nucleus and the π meson. These deviations had been predicted as early as 1934 on the basis of the quantum theory of radiation, but had previously not been supported by such direct and clear-cut evidence. In the case of μ mesons, it was the heavier μ mesic atoms which were studied mostly at first, and the results, together with those from electron scattering by nuclei, led to a much more accurate picture of the distribution of charge in the nucleus (V. Fitch and J. Rainwater, 1953). It turned out that for heavy elements the radius (actually square root of the average value of the square of the radius) of the charge distribution was given by $r = r_0 A^{1/3}$ where $r_0 = 1.2 \times 10^{-13}$ cm. This result was in contrast with earlier estimates of the radius which had given r_0 between 1.3 and 1.5×10^{-13} cm.

The "small" value of r_0 was confirmed by the study of electron scattering by nuclei (R. Hofstadter and coworkers, 1953), in experiments which eventually led to a quantitative determination of the shape of the charge distribution. The difference in the values of r_0 just mentioned is not a discrepancy; the nucleus has a different apparent radius depending on what method is used to look at it. The larger values are obtained from such methods as fast neutron scattering in which the finite range of interaction of nuclear forces makes the nucleus appear larger.

Another discovery in elementary particle physics which made possible an entirely new kind of insight into nuclear structure was that of the so-called Λ hyperfragments or Λ hyperons (M. Danysz and J. Pniewski, 1953). These are nuclei in which a neutron or proton is replaced by a Λ^0 particle. The resulting system lasts about 10^{-10} sec., which is the time it takes a free Λ^0 to decay into proton and π meson. The great virtue of the Λ^0 from the point of view of the study of nuclear structure is that the Pauli principle does not restrict the states a single Λ^0 can occupy in a nucleus formed of neutrons and protons.

Another discovery came out of experiments using proton beams of 100–400 Mev energy. It was found that those protons which are scattered without loss of energy are very strongly polarized; *i.e.*, the scattered protons have spins almost all of which point to one side of the plane determined by the line of flight of the incident and scattered proton. On the other hand, for incident protons of energies of 10 Mev the polarization effect is very small. Similar effects were found for neutrons. This remarkable polarization of high-energy particles made possible a series of important investigations on the spin dependence of nuclear forces.

The importance of high-energy investigations for nuclear physics was emphasized with the discovery of the antiproton (O. Chamberlain *et al.*, 1955). The existence of this particle as well as the confirmed (1956) existence of the antineutron was indispensable for the consistency of nearly all then existing attempts at a fundamental theoretical interpretation of nuclear properties. It was comforting to the theoreticians, whose attempts at a quantitative theory of nuclear forces had been frustrated, to find that one of their basic ideas was correct. In any case, the interaction of antiprotons and antineutrons with nuclei provides an important piece of evidence about the nature of nuclear forces (*see* ANTIMATTER).

NUDISM. This article deals with the conscious, intentional movement to practise nudity without separation of the sexes which commenced at about the beginning of the 20th century in the German *Nacktkultur* ("naked culture") groups. Prior to World War I they consisted largely of middle-class persons of rather strong nationalistic tendencies. Between the two world wars, the movement expanded considerably not only in membership but in its range of opinions, extending from the most conservative to the most radical. Several books and magazines describing, and some of them advocating, nudism were published.

Mainly following the German example, nudist societies were formed in England, France, Scandinavia and a few other European countries. During the 1930s similar societies were formed in the United States and Canada. The nudist movement was hindered by World War II. It has not made much progress in most of the Roman Catholic and Latin countries.

Nudist groups have been organized as membership societies or as proprietary enterprises. They have dreamed and talked of self-sustaining agricultural and industrial colonies in a suitable environment which would adopt the simple manner of life and humanitarian democracy of nudism. Such colonies as enclaves in a predominantly clothed society are hardly feasible. For the immediate future only private terrains for leisure time and recreational use are practicable. The next step may be the setting aside of some of the public baths and parks for nudist use, as has been done in a few German cities.

Prevailing moral conventions, legalized in many jurisdictions, render it difficult, especially for women, to join nudist organizations. While census enumeration of extra-legal groups is not possible, there are probably not more than several hundred thousand such members in the whole world. There is perhaps a somewhat larger number who practise nudism in small family and private groups.

The Rationale of Nudism.—Man originated as a nude animal, perhaps covered with fur. The habit of clothing the body has varied greatly in time and place. The need for protection from cold climate and from harmful animals and plants, and decoration of the body produced various types of garments.

Cultural evolution gave rise to secondary reasons for clothing. Wealth and property rights attached a symbolic meaning to dress. The garb and ornamentation became indicative of rank and wealth. The apparel has often had a ceremonial and ritual significance. Property rights in women emphasized the concealment of the female body. These factors led to powerful dress conventions, and often to ridicule and persecution of unconventional raiment, and especially of the nude body.

There arose the belief that it is immodest and indecent to expose the human, and especially the female, body, and the sexual organs of both sexes. Shame has usually been experienced at violations of these conventions as to clothing, and penalties have been imposed upon such violations.

The nudist movement is a reaction against these dress conventions. Nudists have argued that clothing cuts off the human body from the air and sunlight, and that the practice of nudity is beneficial for health, and thereby improves human beauty. It aids the rearing and education of the young by acquainting and accustoming them to the sexual traits of both sexes, whereas concealment of the body from infancy creates many harmful mental complexes.

Under society's conventions nudity is forcibly and gratuitously associated with sex in the youthful mind. It is asserted that the practice of nudism aids sex education, is the best preparation for mating and marriage, and is a powerful eugenic factor by uniting the healthiest human beings.

Its advocates hold that nudism creates a higher standard of sincerity and frankness between the sexes, by removing the last artificial barrier. It helps to destroy the notion that sex is peculiarly, and perhaps perilously, mysterious and harmful, especially in women. It weakens sex segregation and strengthens human solidarity. It encourages comradeship between the sexes in work and play, and emphasizes the disutility of clothing in many respects.

Nudism has been criticized and attacked from somewhat different points of view. On the one hand, it is alleged that the sexual areas, such as the pubic hair, the female breasts and the masculine reflex, namely, the penile erection, arouse sexual emotions (in public) and are therefore indecent and unfit to be seen.

On the other hand, it is asserted that the art of dress conceals much ugliness, and enhances the variety and beauty of human existence. Furthermore, nudism, by complete exposure, is accused of decreasing visual sex stimulus, though tactile, olfactory, auditory and gustatory stimuli may be increased. Nudism is therefore alleged to be puritanical and ascetic.

The argument against nudism that the human body, or any part of it, is indecent in the sense that it necessarily and almost inevitably arouses passionate feelings, especially in the male sex, is refuted by nearly every observer of nudist practices. Shame, or a painful consciousness of guilt at the sight of the body, disappears almost immediately. This demonstrates that it is due to artificial modesty caused by prevailing conventions of dress, and is not inherent.

Nudists hold that the movement has psychological and sociological significance for the education of the young and the relations between the sexes, and that it may aid the spread of democracy by eliminating status symbols and artificial insignia of inequality.

NUER, a Nilotic people, some 300,000 in the 1960s, who live in the marshy and savanna country on both banks of the Nile in the southern Sudan. They are a cattle people, devoted to their herds, although milk and meat must be supplemented by the cultivation of millet and the spearing of fish, in which the many rivers, streams and lakes of their country abound. Since the land is flooded for part of the year and parched for the rest of it, the people lead a transhumant life, spending the rainy season in permanent villages built on the higher ground and the dry season in riverside camps where there are water and pasturage even at the height of the drought.

Politically, the Nuer form a group of tribes. There is little unity and much feuding within a tribe; the frequent homicides are settled, if they are settled at all, by payments of cattle effected through the mediation of a priest of the leopard skin. Such unity as they display is partly due to the fact that each tribal territory is owned by one or other patrilineal clan. The members of a clan have in their territory a slightly privileged status, although they form a minority of its population. The majority belong to other clans or are descendants of the neighbouring Dinka people, large numbers of whom have been subdued by the Nuer and incorporated into their society.

In each tribal area the men are divided into six age sets. A boy is initiated into his set at puberty with various rites, including the cutting of six deep cuts, running from ear to ear, across his forehead. All boys initiated during a period of about six years belong to the same set. Then there is a four-year interval during which no initiations take place, at the end of which a new age set is formed.

Marriage, which is polygynous, is marked by the giving of cattle by the bridegroom's people to the bride's kin, both paternal and maternal, and by betrothal and wedding ceremonies. The levirate is practised; and since it is held that every man must have at least one male heir, it is the custom for a man's kin to marry a wife to his name and to beget children by her should he die unmarried.

The Nuer clans involve segmentary lineages to which the Nuer attach great importance, and everyone knows his exact genealogical relationship to every member of his lineage and clan. Apart from these agnatic relationships, they attach importance also to kinship ties through their mothers and to affinal ties, and a Nuer can establish a kinship link of one sort or another with most of the people he meets.

The Nuer may be said to be a very religious people. They pray and sacrifice beasts of their flocks and herds to a spirit associated with the sky, but also thought to be ubiquitous, like the air. This spirit is conceived of as a single creative spirit in relation to mankind as a whole, but it is also figured in different representations in relation to different social groups, such as clans, lineages and age sets, and it may then be symbolized by material forms, often animals or plants. *See* also NILOTES.

NUEVA ECIJA, an agricultural province in central Luzon, Republic of the Philippines, drained by the Pampanga river. Area 2,120 sq.mi. Pop. (1948) 467,769; (1960) 608,362. The eastern part of the province is mountainous but the central and western portions are a part of the level central plain of Luzon. It is the leading rice producing province (in tonnage). Other crops are sugar cane, tobacco, corn (maize), onions and other vegetables. Cabanatuán, pop. (1960) 26,397, on the left bank of Pampanga river, is a chartered city, the provincial capital, and the centre of commercial activity. The western part of the city is primarily commercial (theatres, shops, rice mills, etc.); the eastern part is the site of the government buildings, provincial hospital and schools, but has some commercial activity.

The principal towns are San José, Gapán, Cuyapo and San Antonio. After World War II, Nueva Ecija became the principal centre of dissident activities by the Hukbalahaps until the rebellion ended in the mid-1950s. (AN. C.)

NUEVA ESPARTA, a state in Venezuela, consists of about 70 islands and cays extending for a distance of some 320 mi. along the Caribbean coast. Area 444 sq.mi. Pop. (1961) 89,492, most of which live on Margarita Island (*q.v.*), the largest and most important of the group.

The capital of the state is La Asunción. The state has important fisheries; 75% of Venezuela's commercial catch takes place in the northeastern area, of which Nueva Esparta forms a major segment. Pearl fishing is important but less so than in the past. There is a small amount of agriculture and a few handicrafts—hammocks, straw hats, pottery and roof tiles. (L. WE.)

NUEVA SAN SALVADOR: *see* SANTA TECLA.

NUEVA SEGOVIA, a small department of Nicaragua, in the central highlands adjacent to Honduras. Area 1,593 sq.mi. Pop. (1959 est.) 36,351, primarily rural. The largest town and departmental capital is Ocotal, pop. (1959 est.) 3,723. Most of the population is in highland basins and valleys in the central part of the department; the remainder of the department is very sparsely settled, owing to rugged relief, poor soils and lack of transportation facilities.

The settled basins and valleys, some with fertile volcanic soils, produce coffee, livestock, corn, wheat, vegetables and subtropical fruits. A second-class road, 15 mi. long, connects Ocotal with the Inter-American highway. (C. F. J.)

NUEVA VIZCAYA, a province of the Republic of the Philippines, in north central Luzon. Area 2,627 sq.mi. Pop. (1948) 82,718; (1960) 138,090. At the junction of the Sierra Madres and the Central Cordillera, it is principally mountainous terrain and is drained by the headwaters of the Cagayán river and its longest tributary, the Magat.

Agricultural products are rice, corn, tobacco, coconuts and livestock. The capital is Bayombong, pop. (1960) 17,499. Solano, Bambang and Bagabag are other principal towns; all four are in the Magat valley. (AN. C.)

NUEVO LAREDO, a border city in the Mexican state of Tamaulipas, across the Rio Grande from Laredo, Tex. Pop. (1960) 92,627. The town has a bullring and some night life for the visiting tourist. Irrigation of the contiguous area by waters from the Rio Grande brought some growth and wealth to the city in the 1950s. At Nuevo Laredo begins the highway leading to Mexico City (757 mi.) via Monterrey, northern Mexico's industrial centre, Ciudad Victoria, and Ciudad de Valles.

The railway from San Antonio to Mexico City also passes through Nuevo Laredo. The city is a cattle and oil centre of growing importance. (J. A. CW.)

NUEVO LEÓN, a northern state of Mexico. Pop. (1960) 1,078,848. Area, 24,925 sq.mi., with its capital at Monterrey (*q.v.*). Crossed by paved trunk highways and railways between Laredo, Tex., the gulf port of Tampico, and Mexico City, the state is a major industrial section and an important agricultural region lying just north of the Tropic of Cancer. With an average altitude of about 5,500 ft., the Sierra Madre Oriental runs southeasterly through the state.

The climate is arid and semiarid in the north, where sandy wastes are covered with cactus and scrub. The eastern slopes are endowed with vegetation, and the mountainous sections are covered with forests; subtropical valleys in the east permit sugarcane cultivation.

There is considerable irrigation. Though there are a number of rivers and streams, none is navigable. Water for irrigation is in part drawn from the international Falcón dam, jointly constructed by Mexico and the United States for hydroelectric power, flood control and agricultural purposes.

Nuevo León produces few minerals, but quantities of cotton, citrus, sugar, cereals (especially maize and wheat) and vegetables. Its fibres have importance, notably *ixtle* from agaves (cactus), which also furnish distilled liquor, mescal. The main importance of Nuevo León lies in its industries. Its iron- and steelworks and smelting plants were the first heavy industry in Latin America, and in addition it supports numerous textile enterprises, a large beer factory and other industrial activities.

Nuevo León became a state in 1824. It was occupied by U.S. forces in the Mexican War. The state has no Indian population and its standard of living is near the highest in Mexico. It has well-developed air connections and good schools, colleges and hospitals. (J. A. CW.)

NUFFIELD, WILLIAM RICHARD MORRIS, 1st VISCOUNT (1877–1963), British automobile manufacturer and philanthropist. As William Richard Morris, he was born at Worcester on Oct. 10, 1877, the son of a farm labourer. The family moved to Oxford in 1880. When William was 15 years of age, his father's illness obliged him to give up his ambition of studying medicine and go out to work. The bicycle era was just beginning among undergraduates, and William set up a repair shop behind his home in James street, Cowley. He also built machines to order and raced his models with success. Later he sold and maintained motorcycles, building as many as his limited finances allowed, and naturally extended his interest to cars. In 1903 he took in a partner, but the garage went bankrupt. In 1904, with only his own tools left and a £50 debt, he started again. That same year he married Elizabeth Maud Anstey (d. 1959), whose parents lived in Oxford and who also was a keen bicyclist. There were no children.

By dint of hard work and constant application, Morris' business began to prosper again. He set up works in Cowley, and the first Morris-Oxford, an 8.9-h.p. two-seater, appeared in 1913, to be followed by the equally famous Morris-Cowley (11.9 h.p. after he had visited the United States with a designer and had contracted to buy an engine to fit into his English chassis. Then, as later, Morris aimed to produce small, reliable vehicles at the low prices made possible by standardization and mass production, and in doing so he revolutionized the British automobile industry much as Henry Ford had done in the U.S. Morris Motors Ltd., founded in 1919, survived the 1920–21 motor slump because Morris boldly slashed his prices (during 1921 the price of the Cowley four-seater dropped from £525 to £341). From then on his business expanded, and in 1923 the flourishing Morris Garages built the first MG. In the same year Morris founded Morris Commercial Cars Ltd., and in 1927 he acquired Wolseley Motors Ltd. Morris Motors Ltd. was reorganized in 1935–36 to include these three companies, and it also absorbed Riley (Coventry) Ltd. in 1938. When the firm merged with the Austin Motor company in 1952, the resulting company, the British Motor corporation, was the third largest automobile company in the world.

Morris was made a baronet in 1929 and a baron in 1934. In 1938 he became Viscount Nuffield. From about 1933 onward he began to relegate administrative control of his businesses to his senior executives—he never had any close colleagues—and to devote himself to charitable works, each of which he planned with great care and to which his donations exceeded £30,000,000 in all. Among the principal beneficiaries are hospitals; war charities; Morris employees; the Nuffield Institute for Medical Research, Oxford (founded 1935); the Nuffield trust (1936); Nuffield college, Oxford (1937); and the Nuffield foundation (1943), which aims to further "health . . . social wellbeing . . . care of the poor . . . and education."

A man of determination and an enlightened employer, Lord Nuffield was admired as an outstanding figure of British industry and revered as a great philanthropist. He died at his home near Huntercombe, Henley-on-Thames, on Aug. 22, 1963.

See P. W. S. Andrews and E. Brunner, *Life of Lord Nuffield* (1955). (M. Th.)

NUISANCE, a legal term used to denote a human activity or a physical condition on land that is harmful or offensive to others. A distinction must be drawn between a public nuisance and a private nuisance. A public nuisance is an offense against the state, either (1) because the activity occurred or the condition was created in a public place or on public land, or (2) because the activity or condition affects the morals, safety or health of the community. Illustrations of the former are obstructions of a public road and the pollution of streams, while the running of houses of prostitution and the keeping of explosives are examples of the latter. A private nuisance is an activity or condition that causes an interference with the use and enjoyment of the neighbouring privately owned lands, without, however, constituting an actual invasion of the possession of the neighbours. Thus, excessive noise, noxious vapours, disagreeable odours and vibrations may constitute a private nuisance to the neighbouring landowners, although there has been no physical invasion of their lands either above or below the surface.

A public nuisance, as such, is only actionable by the state, either by way of criminal proceedings, injunction or physical abatement. However, the same activity or conduct that constitutes a public nuisance to the community may also create a private nuisance to the neighbouring landowners. Thus, the conduct of a business in violation of a zoning ordinance creates a public nuisance, but it may also be actionable as a private nuisance by neighbouring residential landowners upon proof of decrease in market value of their homes as a result of this business activity.

Since a private nuisance is based upon interference with the use and enjoyment of land, it is only actionable by persons who have a property interest in such land. Where the interference inflicts no physical damage to the land but merely makes its use and enjoyment less comfortable, the courts look at the character of the neighbourhood to determine whether the activity or condition is an unreasonable interference with the use and enjoyment of the neighbouring landowners. Thus, a factory in a predominantly residential area may be a private nuisance while the same business in a commercial area would not be. On the contrary, an activity or condition that causes physical damage to the neighbouring land will be held to be an actionable nuisance irrespective of the character of the neighbourhood. These are usually cases involving vibrations that cause walls to crack or noxious vapours that destroy vegetation. The judicial remedies available in case of a private nuisance are an action at law for money damages or a suit in equity to enjoin the operation or continuance of the activity or condition. Where the abatement of a nuisance by injunction will impose an excessive hardship on the community, the usual practice of the courts is to deny an injunction and award money damages for the injury suffered by the neighbouring landowners. Illustrations of this are cases involving factories employing many workers in the community, who would be deprived of their livelihood if the factory were closed or forced to move.

NUKUS, capital of the Kara-Kalpak Autonomous Soviet Socialist Republic (part of the Uzbek S.S.R.) in the U.S.S.R., is situated on the right bank of the Amu-Darya river at the head of its delta 18 km. (11 mi.) from the railway station of Khodzheili. Pop. (1959) 39,000. Founded in 1933 as a town, Nukus has a large alfalfa-processing plant and a number of small light industries mostly producing food and clothing. There are a teachers' training college, a medical training school, a museum and a theatre. (G. E. Wr.)

NULLIFICATION (State Interposition) was a doctrine that asserted the right of a state in the American federal union to prevent within its borders the enforcement of an act of the federal government not authorized by the U.S. constitution as interpreted by the highest legislative authority of the state. The doctrine reached its most advanced point of theoretical development and application in 1832 in South Carolina. The best explanations of nullification are to be found in the writings of John C. Calhoun (*q.v.*), who may have promulgated the doctrine in order to forestall a secession movement in his state. Calhoun and his precursors, who had produced in South Carolina an incipient form of the doctrine, disclaimed originality for their basic ideas, arguing that they were derived from Jefferson's Kentucky resolutions of 1798, Madison's Virginia resolutions of 1798 and report of 1799, and the Kentucky resolutions of 1799.

The resolutions that Jefferson drafted for the Kentucky legislature in 1798 asserted that the constitution of the United States was a compact subscribed to by the states, which had delegated specific powers to the federal government and retained all others; "that the government created by the compact was not made the exclusive or final judge of the extent of the powers delegated to itself"; and that the states could declare null and void within their boundaries those acts that they deemed not authorized by the U.S. constitution.

Although the Kentucky resolutions of 1799 used the word nullification and referred to the states as sovereign and independent, they were not incompatible with the view of Madison and others among his contemporaries that sovereignty in the United States was divided between the federal and state governments. Neither Jefferson nor Madison repudiated the view generally held by the framers of the constitution that the federal judiciary possessed an implied power to pass upon the constitutionality of federal and state legislation, but they denied that the states must accept its decisions as final in all cases.

Calhoun's view of the judiciary was the same as Madison's, but he rejected unequivocally and explicitly the theory of divided sovereignty. He based his interpretation of nullification on the premise that each of the states was completely sovereign, and as such, when acting through a special convention capable of ratifying the U.S. constitution or revising the state constitution, could either nullify an unconstitutional federal act or withdraw from the union.

Calhoun's most distinctive contribution to the theory of nullification was his rationale of it as an integral part of the American system of government, with aims that were positive, conservative, peaceful and national. For Calhoun, nullification was the means by which a minority in the nation, if it happened to be in the majority in a single state, could utilize a state government to force the national majority either to compromise with the minority by consenting to a revision of federal legislation or to obtain a constitutional amendment that would grant an undisputed authority to the federal government to overrule the constitutional opinion of the nullifying state. He expressed confidence that the practical outcome of nullification would be compromise or constitutional amendment, for, he argued, the national majority would surely prefer peaceful and orderly procedures to the alternatives of anarchy or civil war.

What happened in South Carolina and the national capital in 1832 and 1833, he could reasonably interpret as a vindication of his expectations. In Nov. 1832 a special state convention in South Carolina, taking the position that the delegated power of congress to levy imports was intended solely for the purpose of raising revenue and for no such purpose as encouraging manufactures, declared the tariff laws of 1828 and 1832 unconstitutional, announced that they would become null and void in the state after

Feb. 1, 1833, and warned that secession would be the consequence of federal coercion.

On Dec. 10, 1832, Andrew Jackson issued a presidential proclamation denouncing and refuting the doctrine of nullification, and in Jan. 1833 a bill was introduced in congress authorizing the president to use force to collect import duties. However, the same congress that had passed the tariff bill of 1832 in June and that was to approve the Force bill adopted the compromise tariff of 1833 on March 1. From Calhoun's standpoint, South Carolina's action had forced representatives of the national majority in congress to reconsider and to compromise with the minority.

Never in U.S. history has nullification, as it was expounded by Calhoun, been tested in all of its ramifications, although, before 1865, one of its strands or another was present in numerous federal-state disputes.

In South Carolina, the one state where an ordinance of nullification was approved by a special state convention, the controversy was settled before attempts were actually made to stop collection of import duties.

Following the supreme court decision in the case of *Brown* v. *Board of Education* (1954), declaring racial segregation in the public schools to be unconstitutional, nullification was once again discussed in the south by defenders of segregation, but no state government chose to imitate what South Carolina did in 1832. Instead, the course generally followed was to adopt state-interposition resolutions similar to the Virginia resolutions of 1798 and to avoid compliance wherever and whenever litigation, evasive legislation or an absence of federal-court decrees would permit.

NUMANTIA, a Celtiberian town near modern Soria on the upper Douro (Duero) river in Spain, lay on a hill at the junction of two rivers. It was founded on the site of earlier settlements (from 2000 B.C.?) by Iberians who penetrated the Celtic highlands about 300 B.C. Later it formed the centre of Celtiberian resistance to Rome, withstanding attacks by Cato (195), Q. Fulvius Nobilior (153), M. Claudius Marcellus (152), Q. Pompeius (141–140) and Popillius Laenas (139–138). Finally Scipio Aemilianus, with 60,000 troops against 4,000 Numantines, blockaded it by establishing six miles of continuous lines of circumvallation, with two main and five subsidiary camps at intervals. After a siege of eight months Numantia was reduced by hunger and the survivors capitulated (133). Its destruction ended all serious resistance in Celtiberia to Rome. Numantia was rebuilt by Augustus, but it had little importance, except as a stage on the road between Caesaraugusta (Saragossa) and Asturica (Astorga). In the 11th century A.D. a village named Garray was built at the foot of the hill. The site of Numantia was excavated by Adolf Schulten (1905–12), who revealed the Celtiberian town and Scipio's siegeworks as well as other Roman camps in the neighbourhood.

NUMA POMPILIUS, successor to Romulus as king of Rome (traditionally 715–672 B.C.). He can be accepted as a historical personage, but many of the details of his reign must be regarded with skepticism. His name indicates a Sabine origin and indeed he is said to have come from the town of Cures in the Sabine district and to have been the son-in-law of Titus Tatius. In legend he is the peaceful counterpart of the more bellicose Romulus, whom he followed after an interregnum of a year during which the sovereignty had been exercised by the members of the senate in rotation. He is credited with the founding of nearly all the early religious institutions, the formulation of the religious calendar and the organization of the priestly colleges at Rome. These reforms were, however, undoubtedly the result of centuries of religious development going back to prehistoric times and continuing down into the republican era and thus are not to be assigned to any single man.

Numa's calendar reform involved the addition of two months to an original ten and the assignment of regular dates for the annual religious festivals, thus fixing the days of business and holiday. According to tradition he built the temple of Janus, whose doors were open in times of war and closed in times of peace, appointed the first flamens (priests) of Jupiter, Mars and Quirinus; organized the Vestal Virgins along the lines of the cult at Alba; appointed the 12 Salii to supervise the worship of Mars Gradivus; established the Regia; and appointed the first *pontifex maximus*.

Several corruptions in the legend are obvious: a supposed relationship with Pythagoras, which is chronologically impossible, and the clear forgery of 14 books in Latin and Greek relating to philosophy and pontifical law supposedly written by Numa and uncovered at the foot of the Janiculum in 181 B.C. They were ordered to be burned as tending to undermine the established religion. The story of his connection with the nymph Egeria who purportedly inspired him in much of his religious reform, is likewise a comparatively late interpolation.

NUMBER means a positive integer such as 17, a real quantity such as π or -2, or an element of any of various abstract mathematical generalizations of the system of positive integers and the system of real numbers. These generalizations include complex numbers, quaternions and other hypercomplex numbers, modular numbers and transfinite cardinal and ordinal numbers; all these types of numbers will be defined below.

POSITIVE INTEGERS

Definition of Cardinal Numbers.—The concept of a positive integer arose in prehistoric times from recognition of the fact that the number of elements in any class (say the number of sheep in a herd) can be represented in various ways (say by a pile of stones). The essential idea is that there must be a one-one correspondence between the sheep in the herd and the stones in the pile. By this we mean that it must be possible to pair off one sheep with each stone, in such a way that no sheep is counted twice, and no sheep and no stones are left over.

In the same spirit, modern mathematicians define a cardinal number as a mark associated with a class, and with all other classes in one-one correspondence with this particular class. Thus the integer 5 is the mark associated with the class of fingers on a hand and with all other classes whose elements can be paired off with the fingers on a hand.

A large variety of marks to represent the different positive integers have been developed by different civilizations. These are discussed elsewhere (*see* NUMERALS AND NUMERAL SYSTEMS). The positional notation developed by the Hindus and Arabs, in which the position of a digit to the left of the decimal point indicates the power of the radix or base ten involved, is incomparably superior to earlier systems. However, it is not to be supposed that the base ten has any unique qualifications. Our interest here is not in systems of notation or effective computation (*see* ARITHMETIC; COMPUTER; OFFICE MACHINES AND APPLIANCES) but in the fundamental ideas which underlie the use of number. Two of these are addition and multiplication.

Addition and Multiplication.—If a and b are the integers (cardinal numbers) for two classes A and B having no elements in common, and if these classes be combined to form a new class S, then the integer s representing the class S is called the sum of a and b, and we write $s = a + b$.

From this definition we easily prove the commutative and associative laws of addition,

$$a + b = b + a \quad (1)$$
$$a + (b + c) = (a + b) + c$$

Here and below, the equality sign means that the classes represented by the two sides of the equation can be placed in one-one correspondence. Thus, both $a + (b + c)$ and $(a + b) + c$ represent the combination of three classes A, B, C without common elements, having a, b, c elements, respectively.

Similarly, there may be a classes, each of which contains the same number b of elements, while no two of these classes have an element in common. If all these classes are combined to form a new class P, the integer p representing P is called the product of a and b, written $p = a \times b$.

From this definition, one can also prove the commutative and associative laws of multiplication,

$$a \times b = b \times a \tag{3}$$

$$a \times (b \times c) = (a \times b) \times c \tag{4}$$

as well as the distributive law, which asserts that

$$a \times (b + c) = (a \times b) + (a \times c) \tag{5}$$

Brief further discussions of laws (1)–(5) may be found elsewhere (*see* ASSOCIATIVE LAWS; COMMUTATIVE LAWS; DISTRIBUTIVE LAW); formal proofs may be found in textbooks on mathematics (*see* G. Birkhoff and S. MacLane, *A Survey of Modern Algebra*, ch. xii [1953]). Informal graphical proofs follow.

For example, $a \times b$ is the number of elements in a rectangular array of a rows and b columns: rotation through 90° converts this into a rectangular array of b rows and a columns. Again, $a \times (b + c)$ is the number of elements in a rectangular array of a rows and $b + c$ columns. This array is the sum of two rectangular arrays without common elements, having respectively a rows and b columns, and a rows and c columns. This is $(a \times b) + (a \times c)$.

The laws (1)–(5) are often called the five fundamental laws of arithmetic; in addition, the special unit law

$$a \times 1 = a \tag{6}$$

is evident. Other laws also follow from a detailed logical analysis of the situation. For example, equality satisfies the reflexive law, that $a = a$; the symmetric law, that $a = b$ implies $b = a$; and the transitive law, that $a = b$ and $b = c$ imply $a = c$. Moreover, addition and multiplication are single-valued operations, so that if $a = b$, then $a + c = b + c$ and $a \times c = b \times c$. To explain the relation of such laws to our definitions, consider the statement that $a = b$ implies $a + c = b + c$. This means that if there is a one-one correspondence between two classes A and B, and if C is any class having no elements in common with A or B, then there is a one-one correspondence between the combination (sum) of A and C and that of B and C.

However, a good understanding of the laws of arithmetic is possible on the basis of (1)–(6) alone.

Ordinal or Inductive Definition.—In the last two sections the concept of a positive integer was based on the concept of a class and general principles of the logic of classes. But it is also possible to take a more formalistic view and to base arithmetic on laws (1)–(6) without referring to the idea that integers represent classes.

We must first know the order of the integers (*i.e.*, which positive integer follows which). Then if we start with the principle that $a + 1$ is the successor of a (number following a), and apply repeatedly the special case

$$a + (b + 1) = (a + b) + 1 \tag{2'}$$

$c = 1$ of the associative law, we readily get the addition table. Thus, we get $5 + 1 = 6$, $5 + 2 = 5 + (1 + 1) = (5 + 1) + 1 = 6 + 1 = 7$, etc.

Similarly, the multiplication table can be constructed ordinally from the unit law (6) and the following special consequence

$$a \times (b + 1) = (a \times b) + (a \times 1) = (a \times b) + a \tag{5'}$$

of the distributive laws (5) and (6). Thus, we get $5 \times 1 = 5$, $5 \times 2 = 5 \times (1 + 1) = (5 \times 1) + 5 = 10$, etc.

Hence, we can say that the identities (2), (5), (6) imply all the arithmetic of positive integers, since they tell us how to add and multiply any two positive integers.

G. Peano put this principle in an even more striking form about 1900. He first characterized formally the sequence of positive integers by the following postulates: (i) each positive integer n has a successor, written n^+; (ii) $m^+ = n^+$ implies $m = n$; (iii) there is just one positive integer, called 1, which is not the successor of any number; (iv) any set C of positive integers which includes 1, and which includes n^+ if it includes n, must include every positive integer. Condition (iv) is called the principle of finite induction; it is intuitively evident since C includes 1, includes $2 = 1^+$ since it includes 1, includes $3 = 2^+$ since it includes 2 and so on indefinitely. It is really used above when we state that (6) and (5′) define $a \times m$ for all m.

Peano then developed the entire arithmetic of positive integers from postulates (i)–(iv), without making any other assumptions. He first constructed the addition and multiplication tables as we did above, but introducing $m + 1 = m^+$, (2′), $m \times 1 = m$ and (5′) as definitions. He then proved laws (1)–(5). The chain of reasoning involved is long (*see* C. C. MacDuffee, *An Introduction to Abstract Algebra* [1940]). We give here the special case $m + 1 = 1 + m$ of the commutative law as a sample. The law $1 + 1 = 1 + 1$ is evident. Assuming $1 + n = n + 1$, we have $1 + n^+ = (1 + n)^+$ by definition, $(1 + n)^+ = (n + 1)^+$ by assumption and $(n + 1)^+ = (n^+)^+ = n^+ + 1$ by definition. Hence the set of positive integers m for which $m + 1 = 1 + m$ is true includes 1, and includes n^+ if it includes n; hence, by postulate (iv), it includes every positive integer.

The other proofs make similar use of postulate (iv). Using it, we can further prove the cancellation laws

$$a + m = a + n \text{ implies } m = n \tag{7}$$

$$a \times m = a \times n \text{ implies } m = n \qquad (a \neq 0) \tag{8}$$

The proof of the laws of cancellation in terms of the concepts of class and one-one correspondence alone, and without the use of finite induction, is difficult for reasons which will appear later in the discussion of transfinite cardinal numbers.

Order Properties.—We can easily define the relation $a \leqq b$ in terms of classes, to mean that there is a one-one correspondence between a class A containing a elements and a subset of a class B containing b elements. In this definition, we include B as a subset of itself.

From this definition, it is easy to prove that one can add and multiply inequalities. Thus,

$$a \leqq b \text{ implies } a + c \leqq b + c \tag{9}$$

$$a \leqq b \text{ implies } a \times c \leqq b \times c \qquad (\text{if } c \geqq 0) \tag{10}$$

The restriction $c \geqq 0$ in (10), like the restriction $a \neq 0$ in (8), is added to provide for later generalizations; it is automatically fulfilled in the case of positive integers. Again, $a \leqq b$ and $b \leqq c$ imply $a \leqq c$. In addition,

for any a, b, either $a \leqq b$ or $b \leqq a$; if both hold, then $a = b$ (11)

However, the proof of this, like the proof of (7)–(8), is not easy without the use of finite induction; *i.e.*, no simple proof based on the concepts of class and correspondence is known.

Peano's definitions show that we can define addition and multiplication of positive integers in terms of the order relation. This is because m^+ is defined by the properties that $m^+ > m$, and that $n > m$ implies $n \geqq m^+$. It is curious that we can conversely define order in terms of the operation of addition. In fact,

$$a + x = b \text{ has a solution in positive integers if and only if } a < b \tag{12}$$

Subtraction and Division.—We have not introduced subtraction and division as fundamental operations for the simple reason that they can be defined as the inverses of addition and multiplication, respectively. Thus, the difference $a - b$ of two numbers a and b is defined as a solution x of the equation

$$b + x = a \tag{13}$$

and the quotient $\frac{a}{b}$ of a by b as a solution y of the equation

$$b \times y = a \tag{14}$$

If we restrict ourselves to positive integers, differences and quotients need not always exist (*cf.* $3 + x = 2$, $3 \times y = 2$), but if they do, laws (7)–(8) guarantee that they are unique.

Furthermore, the usual laws of operation, such as

$(a - b) = (c - d)$ means $a + d = b + c$

$(a - b) + (c - d) = (a + c) - (b + d)$

$(a - b) \times (c - d) = (a \times c + b \times d) - (a \times d + b \times c)$ (15)

and (*see* FRACTION)

$$\left(\frac{a}{b}\right) = \left(\frac{c}{d}\right) \quad \text{means } ad = bc$$

$$\left(\frac{a}{b}\right) + \left(\frac{c}{d}\right) = \frac{(a \times d) + (b \times c)}{bd}$$

$$\left(\frac{a}{b}\right) \times \left(\frac{c}{d}\right) = \frac{a \times c}{b \times d} \qquad (16)$$

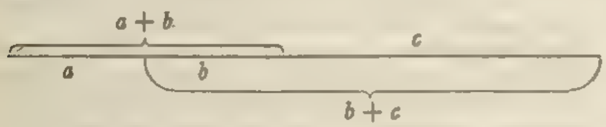
can be proved from laws (1)–(5). This is one reason why laws (1)–(5) are called the fundamental laws of arithmetic.

THE REAL NUMBER SYSTEM

Number as Quantity.—Mankind was early led to the concept of a real number by the need for symbols to represent such geometric quantities as lengths, areas and volumes and such physical quantities as weight and (more recently) electric charge.

The characteristic features of such quantities are that (1) two quantities of the same kind can be added by some obvious geometrical or physical operation (such as laying two segments next to each other on a straight line), and (2) any quantity can be divided into parts. The second feature, of infinite divisibility, is the crudest way of expressing the principle that the real number system is continuous, and not discrete like the system of positive integers.

The commutative and associative laws (1)–(2) of addition are frequently intuitively obvious from the physical definition of addition. Thus, in the case of lengths, it is obvious that $a + (b + c) = (a + b) + c$ since both represent the sum of three segments of lengths a, b, c in order on a line:



It is also obvious that $a + b = b + a$ since the segment $a + b$ can be transformed into the segment $b + a$ by rotation through 180°.

In representing geometrical or physical quantities by numbers, it is usually necessary to choose first an arbitrary unit, such as a foot, a square inch or a pound.

This unit of quantity is assigned arbitrarily the numerical value 1, and exact multiples of this quantity (*i.e.*, sums of an integral number of unit quantities) are assigned corresponding integral values. Since the entire addition table for positive integers can be constructed from the associative law for positive integers (2′), it is clear that the sum of two such quantities must be represented by the sum of the corresponding positive integers.

Multiplication; Number as Ratio.—A simple definition of the product of two quantities is not always possible. For example, if we define the product of two lengths a and b as the area of the rectangle with sides a and b, it may logically be objected that this is a quantity of a different kind.

In order to get around this logical difficulty, the Greeks suggested that a number a should be considered as representing the ratio between a certain quantity and the unit quantity, and never as representing the quantity itself. Thus, 160 lb. is a weight; the number 160 is the ratio of this weight to the weight of a pound.

This idea that numbers are dimensionless ratios has wide applicability. Thus, it leads to plausible "proofs" of the laws of multiplication. For example, the hypothesis that $a \times (b \times c) = (a \times b) \times c$ for all real numbers is given substantial support by the fact that both quantities may be regarded as representing the volume of a box of sides a, b, c. The laws $a \times b = b \times a$ and $a \times (b + c) = (a \times b) + (a \times c)$ can be given similar plausible geometric interpretations in terms of areas.

But these plausible arguments are not proofs in any rigorous sense. They depend not only on postulates for geometry, but also on definitions of area and volume.

The only known way of getting rid of these embarrassing difficulties is to define real numbers abstractly in terms of the system of positive integers, deducing all properties of real numbers by pure logic from these definitions and properties of the positive integers, and using geometrical and physical concepts only to suggest possible postulates and definitions. In this way the properties of real numbers may be made to depend on pure logic and the concept of a class alone (*see* MATHEMATICS, FOUNDATIONS OF).

We shall follow this abstract procedure henceforth.

Rational Numbers.—If we assume that division (except by zero) and subtraction are always possible, we are led inevitably from the system of positive integers to the system of rational numbers (*i.e.*, of positive and negative fractions and integers, and zero).

Thus, let us assume that every equation $by = a$ with positive integral coefficients a, b has a solution y. This corresponds to the idea that a quantity a can be divided into any positive whole number b of equal parts. Let us try also to preserve the five fundamental laws (1)–(5) of arithmetic and the cancellation law (8).

By (8), $by = a$ can have only one solution, which we write $\frac{a}{b}$

It may be shown that the usual rules (16) for adding and multiplying fractions must hold. For example, if $by = a$ and $ds = c$, then $bdy = ad$, $bds = bc$; and so $bd(y + s) = bdy + bds = ad + bc$,

which proves that $\frac{a}{b} + \frac{c}{d} = \frac{(ad + bc)}{bd}$. We can also prove

$$\frac{\left(\frac{a}{b}\right)}{\left(\frac{c}{d}\right)} = \frac{ad}{bc} \qquad (17)$$

whence division by fractions as well as by integers is positive in our new system.

Conversely, we can prove that the rules (16) do give a system in which laws (1)–(12) are valid (we let $\frac{a}{b} > \frac{c}{d}$ mean that $ad > bc$ for positive fractions); in most cases, the proof may be reduced to the corresponding law for the positive integers, by substitution in (16) and cancellation.

Similarly, suppose we assume that every equation $\frac{c}{d} + y = \frac{a}{b}$ has a solution. This hypothesis is suggested by the properties of positive and negative electric charges in physics, by the fact that distance on a straight line can be measured in two directions (right = positive and left = negative), etc.

However, it is not necessary to denote the solution of $\frac{c}{d} + y = \frac{a}{b}$ by such a complicated symbol as $\frac{a}{b} - \frac{c}{d}$. In fact, by (11), either $\frac{a}{b} = \frac{c}{d}$, $\frac{a}{b} > \frac{c}{d}$ or $\frac{a}{b} < \frac{c}{d}$. Hence, by (12), which amounts to saying that $\frac{a}{b} + \frac{x}{y} = \frac{c}{d}$ has a solution if and only if $\frac{a}{b} < \frac{c}{d}$, either $\frac{a}{b} = \frac{c}{d}$ or $\frac{c}{d} + y = \frac{a}{b}$ has a positive solution $\frac{f}{e}$, or $\frac{b}{a} + s = \frac{c}{d}$ has a positive solution $\frac{h}{g}$. Corresponding to these three cases, we write

$$\frac{a}{b} - \frac{c}{d} = 0, \; \frac{a}{b} - \frac{c}{d} = \frac{f}{e} \text{ and } \frac{a}{b} - \frac{c}{d} = -\left(\frac{h}{g}\right)$$

Moreover, instead of proving (15), we can derive the rules for operating and negative fractions and zero from

$$0 + a = a \qquad a \times 0 = 0 \qquad (18)$$

and the mysterious law

$$(-1) \times (-1) = 1 \qquad (19)$$

These in turn are necessary consequences of our laws (1)–(5). Thus, if we define 0 as $1 - 1$, by adding $a - 1$ to both sides of $0 + 1 = 1$, we get $0 + a = a$. Multiplying through $0 + 1 = 1$ by a, we get $a \times 0 + a = a = 0 + a$, whence (canceling) $a \times 0 = 0$. Finally, multiplying the equation $1 + (-1) = 0$, which defines (-1), through by -1, we get $(-1) + (-1) \times (-1) = 0$ by

(5), (6) and (18). Adding 1 to both sides, we get (19) after reduction.

A more thorough study would reveal that a considerable reduction in the number of postulates (fundamental laws needed to imply the others) is possible. Thus, all the laws for the positive fractions can be deduced from the associative law for addition, the distributive laws $a \times (b + c) = (a \times b) + (a \times c)$ and $(a + b) \times c = (a \times c) + (b \times c)$, the unit laws $a \times 1 = 1 \times a = a$, and $1 + 1 \neq 1$.

Irrational Numbers.—Fractions were employed as early as 1700 B.C. by the ancient Egyptians, but it was not until Pythagoras (530 B.C.) that the need for other numbers, like $\sqrt{2}$, was discovered. The need for such irrational numbers is amply corroborated in modern mathematical analysis, where they play a fundamental role in the integral calculus, trigonometry, etc. Pythagoras showed that the ratio x of the diagonal of an isosceles right triangle to the length of a side must satisfy the equation $x^2 = 2$ (Pythagorean theorem). However, no fraction $\frac{m}{n}$ can satisfy $\left(\frac{m}{n}\right)^2 = 2$; that is, $m^2 = 2n^2$ has no solution in integers. For 2 divides m^2, an even, and it divides $2n^2$, an odd, number of times.

Eudoxus pointed out (375 B.C.) that although $\sqrt{2}$ could not be represented exactly by any one fraction, it could be represented as a limit of a sequence of fractions (*see* NUMBER SEQUENCES). Thus, we can represent $\sqrt{2}$ in the form of an infinite decimal: $\sqrt{2} = 1.4142 \cdots$; this amounts to specifying $\sqrt{2}$ as the limit of the sequence of decimal fractions

$$1, \frac{14}{10}, \frac{141}{100}, \frac{1414}{1000}, \frac{14142}{10000}, \cdots$$

These ideas are discussed from the Greek point of view in the tenth book of Euclid's *Elements* (300[?]B.C.).

Their clear exposition from the modern point of view is due to G. Cantor (1871). Real numbers, including both rational and irrational numbers, are defined by Cantor as infinite sequences $x = (x_1, x_2, x_3, \cdots)$, $y = (y_1, y_2, y_3, \cdots)$, $\cdots$, of fractions $x_n, y_n, \cdots$, which converge in the sense that $(x_m - x_n)$, $(y_m - y_n)$, $\cdots$, approach zero as m, n increase indefinitely. We regard x as the limit of the sequence $(x_1, x_2, x_3, \cdots)$.

Equality is defined by making $x = y$ mean that $x_n - y_n$ approaches zero as n increases indefinitely. Addition and multiplication are defined by

$$\begin{aligned} x + y &= (x_1 + y_1, x_2 + y_2, x_3 + y_3, \cdots) \\ x \times y &= (x_1 \times y_1, x_2 \times y_2, x_3 \times y_3, \cdots) \end{aligned} \qquad (20)$$

Laws such as (1)–(17), valid for rational numbers, can be extended to all real numbers by the principle of continuity. For example, each approximating term $(x + y)_n = x_n + y_n$ of $x + y$ is equal to the corresponding approximation $(y + x)_n = y_n + x_n$ of $y + x$; hence, $(x + y)_n - (y + x)_n = 0$ for all n, and $x + y = y + x$ by definition of equality. In general, the principle of continuity states that laws involving continuously varying functions like $x + y$ and $x \times y$ which are valid for arbitrarily good approximations $x_n, y_n, \cdots$ of $x, y, \cdots$ must be also valid for the limit values $x, y, \cdots$.

Another interesting definition of real numbers is due to J. Dedekind (1872). By a section in the class R of fractions, we mean a division of all fractions into two classes L and U, such that $x \leqq y$ for every x in L and y in U. Each fraction (rational number) r determines a section: L consists of the $x \leqq a$ and U of the $y \geqq a$. The other sections define the irrational numbers; thus, the section dividing the fractions into the $x < \sqrt{2}$ and the $y > \sqrt{2}$ (more precisely, the positive y with $y^2 > 2$) may be regarded as defining $\sqrt{2}$. Dedekind's definition can be proved to be equivalent to Cantor's.

The real numbers defined by this process have so far been found adequate for the mathematical treatment of most geometrical and physical quantities such as length, area, weight, electric charge, etc. Not only are the fundamental laws (1)–(6) of arithmetic, the cancellation laws (7)–(8) and the order properties (9)–(11) true, but division (except by zero) and subtraction are always possible. Finally, we have the property that any increasing sequence $x_1 < x_2 < x_3 \cdots$ whose terms are all bounded above by a fixed constant c must tend to a limit.

We shall now discuss other types of numbers; in every case, we shall have to lose some of the properties of real numbers.

GENERALIZATIONS

Complex Number System.—It is clear that the equation $x^2 = -1$ can have no real solution since the square of any real quantity is positive or zero. But we can introduce $i = \sqrt{-1}$ as an imaginary number and preserve those laws (1)–(8) and (15)–(19) of addition and multiplication which do not involve the relation $a \geqq b$. To do this, we must clearly introduce all combinations $a + bi = a + b \times \sqrt{-1}$; these are the so-called complex numbers. Moreover, we must put

$$\begin{gathered} (a + bi) + (c + di) = a + c + bi + di = (a + c) + (b + d)i, \\ (a + bi) \times (c + di) = ac + (ad + bc)i + bdi^2 = \\ (ac - bd) + (ad + bc)i \end{gathered}$$

If we define addition and multiplication of complex numbers by these formulas, laws (1)–(8) and (15)–(19) will be satisfied. For example, it can be verified by substitution that the equation $(c + di)z = (a + bi)$ has the solution

$$z = \frac{a + bi}{c + di} = \frac{ac + bd}{c^2 + d^2} + \frac{bc - ad}{c^2 + d^2}i$$

Furthermore, any quadratic equation $Ax^2 + Bx + C = 0$ with real coefficients has complex roots

$$\frac{(-B \pm \sqrt{B^2 - 4AC})}{2A}$$

since even if $B^2 - 4AC = -D$ is negative, the numbers

$$\frac{(-B \pm i\sqrt{D})}{2A}$$

can be found as complex numbers.

This is a special case of the fundamental theorem of algebra, which asserts that any polynomial equation $x^n + a_1x^{n-1} + \cdots + a_n = 0$ with real or complex coefficients has a complex root (*see* COMPLEX NUMBERS; EQUATIONS, THEORY OF). Thus from a strictly algebraic standpoint, no further generalization is called for.

Although the theory of algebraic equations is greatly simplified by the use of complex numbers, it is necessary to sacrifice the properties of order. If, as by (11), either $a \geqq 0$ or $a \leqq 0$, then by (9) either $a \geqq 0$ or $-a \geqq 0$; in either case, by (10), $a^2 = (-a)^2 \geqq 0$. That is, there is no way in which we could define order so as to satisfy (9)–(11), and make negative numbers have square roots.

Complex numbers are useful not only in pure mathematics (theory of equations and function theory); they are used in discussing alternating electric currents and simplify the solution of many problems in mechanics.

Quaternions and Hypercomplex Numbers.—If we are willing to sacrifice the properties of order, and the commutative law of multiplication as well, we can obtain an interesting further extension of the complex number system, the so-called quaternions (*q.v.*).

Quaternions are numbers of the form $a + bi + cj + dk$, where a, b, c, d are real.

The sum $(a + bi + cj + dk) + (a' + b'i + c'j + d'k)$ is defined as $(a + a') + (b + b')i + (c + c')j + (d + d')k$. Multiplication is defined from the equations (generalizing $i^2 = -1$), $i^2 = j^2 = k^2 = -1$, $ij = jk = ki = -ji = -kj = -ik = -1$. Laws (1), (2), (4)–(8) are satisfied, and subtraction and division (except by zero) are possible. Further, any polynomial equation with quaternion coefficients has a quaternion root.

For many years quaternions were widely used in solving physical problems, but since about 1900 their use in physics has been replaced by that of the vector calculus.

The construction of quaternions can be further generalized. For any set of n^3 real coefficients C_k^{ij}, we can define a linear algebra, or system H of hypercomplex numbers, as follows. The elements of H are the expressions $a_1\epsilon_1 + \cdots + a_n\epsilon_n$, where the "units" $\epsilon_1, \cdots, \epsilon_n$ take the place of the special quaternions l, i, j, k, and are the same for all elements; $a_1, \cdots, a_n$ are arbitrary

real numbers. The sum of $a_1\epsilon_1 + \cdots + a_n\epsilon_n$ and $b_1\epsilon_1 + \cdots + b_n\epsilon_n$ is defined as $(a_1 + b_1)\epsilon_1 + \cdots + (a_n + b_n)\epsilon_n$. Their product is defined as the sum $a_1b_1\epsilon_1^2 + a_1b_2\epsilon_1\epsilon_2 + \cdots + a_nb_n\epsilon_n^2$, where the $\epsilon_i\epsilon_j$ are given by $\epsilon_i\epsilon_j = C_1^{ij}\epsilon_1 + C_2^{ij}\epsilon_2 + \cdots + C_n^{ij}\epsilon_n$.

Although the study of hypercomplex numbers forms an interesting branch of algebra (*see* ALGEBRAS [LINEAR]), the complex numbers and quaternions are the only systems of hypercomplex numbers with real coefficients in which multiplication is associative and division is possible.

Algebraic and Transcendental Numbers.—Numbers which, like $\sqrt[3]{5}$ and $\sqrt{-1}$, represent roots of polynomial equations $a_0x^n + a_1x^{n-1} + \cdots + a_n = 0$ with integral coefficients, are called algebraic numbers. It can be shown that any sum, difference, product or quotient of algebraic numbers is again algebraic, and that so is any root of a polynomial equation whose coefficients a_i are all algebraic numbers. For this reason, algebraic numbers form a closed subsystem of the system of complex numbers, which can be studied without using limits or other infinite processes.

Algebraic numbers have many fascinating properties (*see* NUMBERS, THEORY OF).

Real or complex numbers which are not algebraic are called transcendental. In 1851 Joseph Liouville first provided the existence of transcendental numbers; in 1873 Charles Hermite proved that the base e of natural logarithms was transcendental and in 1882 Ferdinand Lindemann proved that π was transcendental. We now know that the vast majority of real numbers are transcendental (see *Infinite Cardinal Numbers*, below).

Modular Numbers: Fields.—Another interesting class of modular number systems, each containing a finite number of elements, can easily be constructed from the positive integers. For each prime number $p = 2, 3, 5, 7, \cdots$, consider the integers $0, 1, 2, \cdots, p - 1$. The sum $a + b$ and product $a \times b$ of any two of these integers are defined as the remainders of the ordinary sum $a + b$ and product $a \times b$, when divided by p. Thus, if $p = 3$, then $2 + 1 = 0$ and $2 \times 2 = 1 = 4 - 3$; the complete addition and multiplication tables are

+	0	1	2
0	0	1	2
1	1	2	0
2	2	0	1

×	0	1	2
0	0	0	0
1	0	1	2
2	0	2	1

These number systems satisfy conditions (1)–(6), and subtraction and division (except by zero) in them is always possible. They were first studied by C. F. Gauss (*Disquisitiones arithmeticae* [1801]).

Number systems satisfying laws (1)–(6), in which subtraction and division (except by zero) are always possible, are called fields. All the fields having a finite number of elements are known—they are called Galois fields; for each prime power p^n, there is exactly one having p^n elements. An interesting theorem, proved by J. H. M. Wedderburn in 1910, asserts that for systems containing only a finite number of elements, the commutative law of multiplication is a consequence of the other laws (*see* FIELDS).

Hypercomplex number systems with coefficients in a modular field or any other field can be constructed just as easily as if the coefficients were in the field of real numbers.

Infinite Cardinal Numbers.—In the definition of a cardinal number given at the beginning of this article, there is nothing stated which requires the class to be finite. Thus, it is perfectly legitimate to ascribe the mark d (denumerable infinity) to the class J of all positive integers and every other class which can be put in one-one correspondence with J.

Similarly, it is perfectly legitimate to ascribe the mark c (power of the continuum) to the class $R\#$ of all real numbers and every other class which can be put in one-one correspondence with $R\#$.

The definitions of addition and multiplication are still valid, as are the proofs of the basic laws (1)–(6) of arithmetic. The definition of the relation $a \leqq b$ is also valid, and laws (9)–(11) can be proved for infinite numbers as well as for finite numbers; only (11) offers any difficulty.

In fact, we can even define exponentiation for infinite as well as finite cardinal numbers. But we must avoid the usual elementary definition $a^n = a \times \cdots \times a$ (n factors) and define a^b as the cardinal number of the class of all single-valued functions (*see* CALCULUS, DIFFERENTIAL AND INTEGRAL) or rules f assigning to each element x in a class of b elements a single value $y = f(x)$ in a class of a elements. One can then prove easily the usual laws of exponents

$$(a \times b)^s = a^s \times b^s,\ a^{s+t} = a^s \times a^t,\ (a^s)^t = a^{s \times t} \tag{21}$$

One can also connect the infinite cardinal numbers c and d by the interesting formula

$$c = 2^d \tag{22}$$

The main loss in dealing with infinite cardinal numbers is that the laws (7)–(8) of cancellation are no longer valid. In fact, for every infinite cardinal number γ, it can be proved that

$$\gamma = \gamma + 1,\ \gamma + \gamma = \gamma,\ \gamma \times \gamma = \gamma \tag{23}$$

These equations imply that every infinite class can be placed in one-one correspondence with a proper subclass of itself. For example, there is an obvious one-one correspondence between the class J of positive integers $1, 2, 3, \cdots$, and the class E of even integers $2, 4, 6, \cdots$; another between J and the class O of odd integers $1, 3, 5, \cdots$; it follows from the definition of addition that $d + d = d$.

From $\gamma = \gamma + 1$ we easily get $\gamma + 1 = \gamma + 2$, while $\gamma + \gamma = \gamma$ implies $2 \times \gamma = 1 \times \gamma$; hence, neither law of cancellation holds. For this reason it is impossible to extend the system of finite and infinite cardinal numbers to larger systems in which subtraction or division are possible.

From $\gamma + \gamma = \gamma$ it can easily be shown that the class of all integers $\pm n$, 0 has the same cardinal number d as the class of positive integers; from $\gamma \times \gamma = \gamma$, it follows that the class of all rational numbers $\pm \frac{m}{n}$ also has the cardinal number d; this is even true of the class of all algebraic numbers.

This suggests the conjecture that perhaps the class $R\#$ of all real numbers also has the cardinal number d. We shall now disprove this. It would mean that all real numbers could be written in a sequence, S, just as the integers $1, 2, 3, \cdots$, can be so written.

First let us imagine the numbers of this sequence to be written in decimal form. Now certain rational numbers admit of double representation, as is evident from the fact that $0.879999 \cdots = 0.880000 \cdots$. Let us agree, in all such cases, to use the mode of representations by 9s, so that every number shall have a unique decimal representation. We may now construct another number $0 \cdot x_1x_2x_3 \cdots$ as follows. Let the first digit x_1 after the decimal point be chosen apart from 0 and the first digit (after the decimal point) of the first number of S, let x_2 be chosen apart from 0 and the second digit of the second number of S; and so on. There will then be defined a number in decimal form which is obviously distinct from all the numbers of S, which disproves our conjecture.

This disproof by the diagonal process of G. Cantor can be generalized so as to apply to any cardinal number. Thus, there is an infinite sequence of distinct infinite cardinal numbers $d < 2^d = c < 2^c < 2^{2^c} < \cdots$. It is not known whether or not there are others in between the ones listed.

Since the cardinal number of the class of algebraic numbers is d, the preceding argument proves that there exist real transcendental numbers and, in fact, that there are infinitely more transcendental numbers than algebraic numbers.

Infinite Ordinal Numbers.—Consider the infinite sequence of non-negative integers $0, 1, 2, 3, \cdots$. It has the property that every nonempty subset has a first member (so-called well-ordering property). It was observed by Cantor that one can extend this sequence in exactly one way without losing the well-ordering property. Indeed, there must be a first infinite ordinal ω after all the integers, a first ordinal $\omega + 1$ after ω, a first ordinal $\omega + 2$ after $\omega + 1$ and so on. Immediately after the sequence $\omega, \omega + 1,$

$\omega+2, \cdots$, there must be a first ordinal 2ω, followed by $2\omega+1$, $2\omega+2, \cdots$; then 3ω, $3\omega+1$, $\cdots$. Evidently this process of ordinal numeration can be continued, giving numbers of the form (*see* NUMBER SEQUENCES)

$$\begin{array}{l} 0, 1, 2, \cdots \\ \omega, \omega+1, \omega+2, \cdots \\ 2\omega, 2\omega+1, 2\omega+2 \\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot \\ \omega^2, \omega^2+1, \omega^2+2, \cdots \\ \omega^2+\omega, \omega^2+\omega+1, \omega^2+\omega+2, \cdots \\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot \end{array}$$

We can identify each ordinal number α in this sequence with the set of κ preceding α, in order. Thus, 3 corresponds to the ordered set (0, 1, 2), ω with the ordered sequence of all non-negative integers and so on.

If we do this, we can define $\alpha+\beta$ as the result of laying the sequence β after the sequence α, $\alpha\beta$ as the result of substituting the sequence β for each term of the sequence α and α^2 as $\alpha\alpha$. These definitions are consistent with the notations we have introduced; however, $1+\omega=\omega\neq\omega+1$ and $\omega 2=\omega\neq 2\omega$, so that neither addition nor multiplication is commutative. On the other hand, both operations are associative, $(\alpha+\beta)\gamma=\alpha\gamma+\beta\gamma$, and we rescue the one-sided cancellation laws, $\alpha+\beta=\alpha+\gamma$ implies $\beta=\gamma$, $\beta\alpha=\gamma\alpha$ implies $\beta=\gamma$.

There seems to be no reason why the process of ordinal enumeration of the elements of a class C cannot be continued indefinitely until all the elements of the class have been counted. That is, it seems plausible to assume that every class can be well ordered.

Using this assumption, one can prove that $\alpha+\alpha=\alpha$ and $\alpha^2=\alpha$ for all infinite cardinal numbers. However, inasmuch as no infinite class not equivalent to (*i.e.*, in one-one correspondence with) the class of integers has ever been constructively well ordered, this assumption must still be accepted with reservations (*see* MATHEMATICS, FOUNDATIONS OF).

Ordered Fields.—In each of the preceding generalizations of the real number system, we have lost either the order properties (9)–(11), as in the cases of complex, quaternion and modular numbers, or the possibility of subtraction and division, as in the cases of infinite cardinal and ordinal numbers. We shall now show that there exist ordered fields, not contained in the real number system which have both the order properties and the arithmetic properties of the rational and real numbers.

Consider the class of infinite formal power series

$$a(x)=a_{-m}x^{-m}+a_{-m+1}x^{-m+1}+\cdots+a_0+a_1x+a_2x^2+\cdots \qquad (24)$$

which begin with an arbitrary positive or negative integral power $a_{-m}x^{-m}$ of the symbol x with real nonzero coefficient a_{-m}. To add two such series, add corresponding coefficients; thus, $c(x)=a(x)+b(x)$ means $c_n=a_n+b_n$ for all n. To multiply, let the coefficient c_n of x^n in the product $c(x)=a(x)b(x)$ be the sum of all products a_ib_j such that $i+j=n$; thus

$$(x+x^2-x^3+\cdots)(2x^{-2}+3x^{-1}-4+\cdots)= (2x^{-1}+5-3x+\cdots).$$

Define $a(x)\geqq 0$ to mean that $a_{-m}\geqq 0$ in (24). Finally, add 0 to the system, using (18) to define addition and multiplication by zero.

With these definitions, the fundamental laws (1)–(6) can easily be proved. It is also easy to show that subtraction is always possible. Further, division (except by zero) is always possible; thus,

$$\frac{1}{(1-x)}=1+x+x^2+\cdots$$

as in the familiar high-school formula. Hence, the formal power series (24) and 0 form a field (*see* above). Finally, if we define $a(x)\geqq b(x)$ to mean $a(x)-b(x)\geqq 0$, the order properties (9)–(11) hold.

In fact, the only property of real numbers which is not shared by our new system is the completeness property: that any increasing sequence of real numbers, whose terms are all bounded above by a fixed quantity, must tend to a limit. In fact, the increasing sequence $-1<-\frac{1}{2}<-\frac{1}{3}<\cdots$, whose terms are all bounded above by 0, does not tend to a limit in our new system. For example, it does not approach 0, since $-x$ separates 0 from every term of the sequence. Since it can be proved that any ordered field with the completeness property is equivalent to the real number system, we cannot hope to obtain any closer analogue of the real number system.

NUMBERS (in the Hebrew Bible, BEMIDBAR), the fourth book of the Old Testament and also the fourth of the five Books of the Law or Books of Moses or the Pentateuch. It is the only one of these five not known in English by its Greek title (Arithmoi). Tertullian calls it Arithmi, a title similar to that in the Mishna. In the Hebrew Bible it is always named Bemidbar —"In the Wilderness" (Num. i, 1).

Place in the Pentateuch.—In modern times the Pentateuch has been subjected to considerable critical analysis. By the end of the 19th century the "Graf-Wellhausen" hypothesis had gained a general consensus of scholarly favour, its main conclusions being that four major documents, J, E, D and P, lay behind the Pentateuch and that they arose historically in that order. Later criticism has shown the need for some modification of this position, either by more precise literary analysis—the recognition of new sources, such as H (Holiness) or L (Lay), or the identification of strata or recensions of sources already recognized—or by the use of form-critical methods to study the history of a preliterary oral tradition. Two results seem to be firmly established: first, documentary analysis is in general not an instrument for precise and minute separation of verses and even half-verses; and second, whether the sources of the Pentateuch be literary or oral, each one of them contains both very ancient and much more recent material, so that the generally earlier sources (J and E) contain some quite late elements, while the generally later sources (D and P) incorporate some quite early material. This must be kept in mind in studying Numbers, which is composed of the earliest and the latest of the four chief sources. (For a more detailed analysis of the sources of the Pentateuch, *see* PENTATEUCH.)

Yet the place of the Book of Numbers in the Pentateuch cannot be adequately conceived without recalling the unifying and positive purpose which brought and held together the various sources, literary and oral. The Pentateuch is the book of the people of God: it explains to a later age how God once called, gathered and delivered his people out of Egypt, how he made a holy covenant with them at Sinai, how he disciplined them in the wilderness and prepared them to be his people, his servant, among all the peoples of the world. The centre of that story is the Exodus, in which, by the agency of Moses, God gathered, delivered and constituted the tribes of Israel to be his covenant people. Before that central story is told the Pentateuch relates, in the form of myth, how the God who so created his people also created the universe, and, in the form of tribal history, how all the histories of the tribes constituting the Old Testament people of God lead up to the story of the Exodus and find their meaning and significance in it. And after the central story of the Exodus has been told in the narratives of the deliverance at the Red sea and of the covenant at Sinai, the Pentateuch goes on to relate how, in ideal and exemplary fashion, God disciplined his people in the desert, to fashion them into a faithful, loving and obedient people to himself. It is in this setting of the discipline or fashioning of God's covenant people that the Book of Numbers is to be understood.

Contents.—The first part of the book (i, 1–x, 10) is substantially a continuation of the material from Ex. xix to the end of Leviticus. Ex. xix, 1 reports the arrival of the Israelites in the wilderness of Sinai; Num. x, 11 begins the account of the removal of the people from Sinai. The latter part of Exodus tells of the construction of the tabernacle for God's presence. Leviticus is devoted to the establishment of the sacrificial system and of the

priesthood. Numbers i–x, 10 reports the institutions of the Levites and of the symbolic arrangement of the people to symbolize the presence of God in their midst. The second section of Numbers (x, 11–xxi, 9) recounts the journey northward from Sinai and west of Arabah, while the third (xxi, 10–xxxvi, 13) tells of the progress east of the Arabah and the Jordan. Each section contains various laws, the last collection of which (xxxiii, 50–xxxvi, 13) anticipate Deuteronomy in legislating for the conditions that could obtain only after the conquest and settlement of Canaan. In the following table of contents the conventional source symbols (described in PENTATEUCH) are used, without prejudice to the question how far each or any of the sources were, at the time of their assimilation, written or oral (R = Redactor).

i, 1–x, 10 (P):	in the wilderness of Sinai
i:	the numbering of the secular tribes, and the place and function of the Levites
ii:	the arrangement of the secular tribes in the camp and their numbers
iii–iv:	the numbers and duties of the Levites, and their relation to the secular tribes
v–vi:	various laws
v, 1–4:	isolation of the unclean
v, 5–10:	restitution of stolen property
v, 11–31:	ordeal for jealousy
vi, 1–21:	Nazirites
vi, 22–27:	priests' blessing
vii:	princely offerings
viii, 1–x, 10:	various laws
viii, 1–4:	lamps
viii, 5–22:	consecration of Levites
viii, 23–26:	age and service of Levites
ix, 1–14:	supplementary Passover
ix, 15–23:	the fiery cloud
x, 1–10:	silver trumpets
x, 11–xxi, 9:	northward from Sinai
x, 11–36 (JEP):	leaving Sinai
x, 11–28 (P):	time and order of march
x, 29–32 (JE):	Hobab
x, 33–36 (JE):	the ark of the covenant
xi, 1–xii, 16 (JE):	incidents en route
xi, 1–3:	complaints at Taberah
xi, 4–10:	manna
xi, 11–24a:	Moses and Yahweh
xi, 24b–30:	elders and prophets
xi, 31–35:	quails and plague
xii, 1–16:	Miriam, Aaron and Moses
xiii–xv:	in the wilderness of Paran
xiii, 1–17a (P):	12 spies appointed
xiii, 17b–20 (JE):	their instructions
xiii, 21 (P), 22–24 (JE):	their journey
xiii, 25–26a (P):	their return
xiii, 26b–31 (JE), 32 (P), 33 (JE):	their report
xiv, 1–2 (P), 3–4 (JE):	popular despair
xiv, 5–7 (P):	Joshua and Caleb report
xiv, 8–9 (JE):	Caleb's encouragement
xiv, 10 (P):	Yahweh appears
xiv, 11–24 (RJE):	God and Moses
xiv, 25 (RJEP):	a new plan
xiv, 26–38 (P):	divine judgment
xiv, 39–45 (JE):	disobedient advance defeated
xv, 1–16 (P):	meat offerings by Israelites and strangers
xv, 17–21 (P):	meal offerings
xv, 22–31 (P):	offerings for sins of ignorance
xv, 32–36 (P):	sabbath breakers
xv, 37–41 (H):	wearing tassels
xvi–xvii (JEP):	rebellion of Korah, Dathan and Abiram
xvi, 1–2 (JEP):	the rebels' names
xvi, 3–11:	Korah's rebellion
xvi, 12–15 (JE):	rebellion of Dathan and Abiram
xvi, 16–24 (P):	Korah's ordeal
xvi, 25–34:	ordeal of Dathan and Abiram
xvi, 35–50:	Korah's story continued
xvii (P):	sprouting of Aaron's rod
xviii (P):	the duties and dues of priests and Levites
xix (P):	purification from contact with the dead
xx, 1–xxi, 9 (JEP):	the march to the north continued
xx, 1 (JEP):	death of Miriam
xx, 2–13:	miracle at Meribah
xx, 14–21 (JE):	Edomite hostility
xx, 22–29 (P):	death of Aaron
xxi, 1–3 (JE):	varying fortune at Hormah
xxi, 4–9 (JE):	the bronze serpent
xxi, 10–xxxvi, 13:	journey east
xxi, 10–xxii, 1 (JEDP):	toward Jericho
xxi, 10–20 (JEP):	on the march
xxi, 21–32 (JE):	victory over the Amorites
xxi, 33–35 (D):	defeat of Og
xxii, 1 (P):	before Jericho
xxii, 2–xxiv, 25 (JE):	Balaam
xxii, 2–4:	Moab and Israel
xxii, 5–14:	Balak's first invitation
xxii, 15–21:	Balak's second invitation
xxii, 22–35:	Balaam and his ass
xxii, 36–40:	Balaam and Balak
xxii, 41–xxiii, 12:	Balaam's first oracle
xxiii, 13–26:	Balaam's second oracle
xxiii, 27–xxiv, 13:	Balaam's third oracle
xxiv, 14–25:	Balaam's final oracle
xxv, 1–5 (JE):	infidelity with Moab
xxv, 6–18 (P):	infidelity with Midian
xxvi (P):	the Second Census
1–4:	directions
5–51:	the secular tribes
52–55:	allocation of land
57–62:	the Levites
63–65.	Israel reconstituted
xxvii, 1–11 (P):	female inheritance
xxvii, 12–23 (P):	the appointment of Joshua
xxviii–xxx (P):	a miscellany of laws
xxviii, 1–2:	introduction
xxviii, 3–8:	daily offerings
xxviii, 9–10:	sabbath offerings
xxviii, 11–15:	monthly offerings
xxviii, 16–25:	Passover offerings
xxviii, 26–31:	harvest offerings
xxix, 1–6:	trumpet offerings
xxix, 7–11:	atonement offerings
xxix, 12–40:	offerings for the Feast of Tabernacles
xxx:	vows made by women
xxxi (P):	destruction of Midian
xxxii, 1–42 (JEP):	the settlements east of Jordan
xxxiii–xxxvi:	summary and appendices
xxxiii, 1–49 (P):	Israel's route from Egypt to Canaan
xxxiii, 50–56 (PHD):	rule of "no compromise"
xxxiv (P):	boundaries and boundary officers in Canaan
xxxv (P):	levitical cities, refuge, etc.
xxxvi (P):	marriage of heiresses

This analysis reveals the diversity of material out of which, like other books of the Pentateuch, Numbers is made. It has in it some very early fragments of narrative poetry, as in the short quotation from the Book of the Wars of Yahweh in xxi, 14, 15; the song to the well cited in xxi, 17, 18; and the primitive apostrophe of the ark attributed to Moses in x, 35, 36. The so-called Lay document (L), which is older than J or E, is thought to be incorporated into x–xiv, 20 and xiv, 25.

Themes.—But though diverse in origin these different elements are brought together for one purpose. The various themes of the book are made to serve one dominant theme. Numbers is a predominantly priestly document; it stems from and belongs to the postexilic period of Israel's history, when an attempt was made at a theocratic form of government. Numbers is the wilderness tradition of the Hebrew people as it was articulated in such a society. The compilers did not try to give what readers in the 20th century A.D. might think to be a strictly historical record setting out the whole story as it actually happened; rather they used the concepts of a theocratic society to exhibit the meaning of the wilderness tradition as they understood it, and thereby at the same time to enable the members of the theocratic states to understand their own society more profoundly. The past, that is to say, is looked at in the light of the present, and that in turn leads to a deeper understanding of the present in terms of the past and its continuity with the present.

The mutual enrichment of meaning for both past and present can be illustrated in respect of all the major themes of the Book of Numbers. Postexilic Israel reckoned itself to be a people separated from all the nations of the world for God. This is indicated in Numbers by the fact of the census: God's people has a definite number and is distinct from all other nations and tribes.

In the days after the exile Israel placed great emphasis upon the Temple as the place in which Yahweh had chosen to dwell with his people. In the desert, so the tradition of Numbers has it, God dwelt in the midst of his people in the tent of meeting, surrounded by the 12 tribes, as he was in the centre of them as they went on the march.

Later Jewry worshiped Yahweh as an utterly transcendent God, who could not be approached by the ordinary man but had to be sought through the appointed intermediaries of priest and Levite. Similarly, in the desert, Numbers records, God was also known to be transcendent as well as present, and in the same way could be approached by the ordinary worshiper only through the agency of priest and Levite. The tent of meeting was fenced off by the levitical and priestly dwellings, and danger attended the unauthorized intruder into the tent (xvii, 12).

In Palestine after the exile it was taught that God was the one source of the Law, for church and state alike. Numbers also makes it plain that the true ordering of both social and religious life flows from divine commandments to which God's people owe unswerving allegiance.

Later Judaism looked back upon the golden age of prophecy, and so rare a phenomenon had the prophet become that he had to authenticate himself in terms of acknowledged tests (*cf.* Deut. xiii, 1–5; Num. xvi, 28–30). The same situation is shown to have been true of the days in the wilderness, where Moses was the great prophet who received his communication from Yahweh directly and not, like other prophets, in dream or vision (Num. xxi, 8), and where also tests were applied to those who claimed to prophesy for Yahweh, with striking results in certain cases (Num. xvi, 31–33). So it was underlined that in the days of the wilderness as in the time after the exile the gift of prophecy was entirely at the disposal of Yahweh. In another fashion, this is also stated in the story of Balaam, the non-Israelite who was nevertheless called to be a prophet of Yahweh.

In such ways as these the compilers of Numbers looked at and handed on the tradition of what happened "in the wilderness." They achieved two things by their skill: first, by using theological insights common and accepted among themselves, they showed the fundamental meaning of the history of the wilderness wanderings; and second, by indicating a substantial unity between the wilderness and the postexile, they reinforced and deepened the theological principles of their own theocracy. The whole hieratic structure of the postexilic community was able to act with a great deal more self-conscious competence because of this historical review.

Historicity of Numbers.—It will be apparent how alien to the whole spirit of the book and its authors it is to ask how far the book is historically accurate. Did the Israelites camp in the exact formation which Numbers describes in its opening verses? The answer is almost certainly "no." But the description of the camp's ordering was made not in order to convey precise historical information in the modern sense but rather to bring to the surface the basic meaning of the journey, however the camps may have been pitched. Modern men may well seek to press their questions about historical accuracy upon the biblical scholar; such questions can be answered. But in return the biblical scholar must point out that the admittedly "unhistorical" record is not rendered useless either to the historian or the theologian; rather does it then for the first time have a chance to repeat to modern man the meaning and the message its compilers intended it to convey.

There is almost a complete absence of any Deuteronomic influence in Numbers (*see* DEUTERONOMY); the same can be said of the Holiness code (*see* LEVITICUS). The book remains as a bringing together by editors of the late postexilic priestly school of quite old traditions and very recent recensions, and a fusing of these two elements into one book which would enable the postexilic community to understand itself more clearly as the contemporary separated people of God.

Numbers and the New Testament.—Though Numbers is very infrequently, if at all, quoted in the New Testament, it—like other books of the Pentateuch—forms the background in thought and language for many New Testament formulations. There are allusions to Numbers in all but four of the New Testament Books (Philippians, Philemon, II and III John), though actual quotation may in fact be limited to but one occasion. This appears to be in II Tim. ii, 19, where Paul follows the Septuagint text, substituting "Lord" for "God." Paul is making a point typical of Numbers: "The Lord knows those who are his," with the implication that the Lord's people are separate and have their own way of life. The account of the Nazirites in Numbers helps to an understanding of the reference to John the Baptist's diet in Luke i, 15 and to Paul's purification in Acts xxi, 23 ff. Numbers also provides a fuller though puzzling background to the references to Balaam in II Pet. ii, 15, 16, Jude 11 and Rev. ii, 14, and it provides the key to the reference to Korah in Jude 11. But the chief relationship between Numbers and the New Testament is akin to its relationship with postexilic Jewish theocracy, as a means of mutual illumination and interpretation. There are abundant instances of this in almost every book of the New Testament, and perhaps the chief of such mutual interpretations is the figure of Moses, who, like the Lord of the New Testament, did not receive the word of God secondhand, but directly (*cf.* Num. xii, 6–8).

At one point the New Testament exhibits a further development of a Numbers tradition. The story of Balaam in xxii–xxiv is not homogenous, and some scholars have discerned a difference of character in Balaam as between J's description and E's. In J, Balaam is of complete integrity, whereas it is argued that in E he is much more ready to be tempted from his integrity by the prospect of reward. Such a tendency, which is claimed to have begun to show itself in the comparatively short period between the writings of J and E, has become much more marked in P's contribution to the account in Numbers, for here Balaam is a sorcerer who instigates the seduction of Israelite women into idolatry at Peor. He is later reported as dying in battle between the Israelites and the Midianites. In the New Testament as in Josephus and rabbinic writings, Balaam is the type of all false and avaricious teachers.

Influence of Numbers.—It was the "publication" of the Pentateuch that first made the Jewish people the people of a book. Numbers inevitably shared in that vital transformation, and, as shown above, enabled postexilic Judaism to understand itself and its mission more clearly. But the book that is the basis of a people's life must be subjected to constantly developing interpretation, or else both people and book die. Both Judaism and Christianity have developed their own traditions of interpretation, in which Numbers, with the rest of the Pentateuch and indeed the rest of the Old Testament, becomes for the Jewish people and the Christian church respectively one of the documents in the light of which contemporary Jews or Christians are able to understand the way in which God deals with them now, and in the light of that understanding continually return to the text of Numbers to find that its depths are still unfathomed. *See* also BIBLE.

NUMBERS, THEORY OF. The theory of numbers is concerned, in its elementary parts, with properties of the integers, or whole numbers, $0, \pm 1, \pm 2, \cdots$. Examples of such properties which emerged in ancient times are these: the Chinese knew in 500 B.C. that $2^p - 2$ is divisible by p, for prime numbers p; Euclid (300 B.C.) proved that there exist infinitely many primes (otherwise, if p could be the greatest prime, then as a contradiction a larger prime would divide $M + 1$, where M denotes the product $2 \cdot 3 \cdot 5 \cdots p$ of all primes up to p). While most results of this vast and beautiful subject, dealing with the universally familiar whole numbers, are easy to understand, the

proofs of many use the deepest resources of mathematics, and some of the most interesting conjectures are still unproved.

Topics in the theory of numbers will be treated under the following headings:

I. Divisibility and Primality
- 1. Elementary Definitions; Factorization Into Primes
- 2. Residue Classes: Euler's Theorem
- 3. Congruences in One Unknown
- 4. Quadratic Residues; the Quadratic Reciprocity Law
- 5. Factorization of Numbers; Mersenne Primes

II. Representation by Forms
- 1. Binary Quadratic Forms
- 2. Genera of Quadratic Forms; Formulas for Number of Representations
- 3. The Numbers Represented by a Quadratic Form; Universal Forms; Representation of Zero
- 4. Automorphs and Reduction of Indefinite Binary Quadratic Forms
- 5. Diophantine Equations

III. Topics in Analytic Number Theory
- 1. Gauss's Class-Number Conjecture
- 2. Distribution of Primes; Asymptotic Formulas

IV. Additive Theory of Numbers
- 1. Partitions
- 2. The Waring Problem, and Related Problems
- 3. The Goldbach Problem

V. Diophantine Approximation
- 1. Geometry of Numbers
- 2. Diophantine Approximation

VI. Generalizations of Arithmetic
- 1. Algebraic Numbers
- 2. Ideals
- 3. Algebras, and Their Arithmetics

I. DIVISIBILITY AND PRIMALITY

1. Elementary Definitions; Factorization Into Primes.—If a and b are integers, and $a = bc$ for some integer c, then b is called a factor or divisor of a; abbreviated $b|a$, read as b divides a; thus $1|a$ and $a|a$ for every integer a. A prime number is an integer $p > 1$ such that p has no positive factors except 1 and p; examples are 2, 3, 5, 7, 11. Other integers greater than 1 are called composite.

Every integer greater than 1 is either itself a prime or can be expressed as a product of primes in only one way (except for rearrangement of factors). This concept, called the fundamental theorem of arithmetic, is commonly proved by means of a property given by Euclid, namely, if a prime p divides ab, then p divides a or b. To establish this property Euclid showed that if d is the greatest common divisor (g.c.d.) of a and b, then there exist integers x and y satisfying $ax + by = d$ (see *Residue Classes* below). Assuming this, suppose that $p|ab$ but not a; then since p is a prime, the g.c.d. of p and a is 1, $ax + py = 1$, $abx + pby = b$, hence $p|b$.

The symbol (a,b) is frequently used for the g.c.d. of the integers a and b, assumed not both zero. If $(a,b) = 1$, a and b are called relatively prime, or coprime, and a is described as prime to b.

Several independent proofs of the fundamental theorem of arithmetic, based on mathematical induction, have appeared (H. Hasse, 1928; E. Zermelo, 1934; Ferdinand Lindemann, 1933).

See ARITHMETIC.

2. Residue Classes: Euler's Theorem.—Let m denote a given positive integer. Every integer a can be expressed in the form $a = qm + r$, where q is an integer (the quotient on division by m) and r, the remainder, has one of the m values $0, 1, \cdots, m-1$. Two integers a and b having the same remainder r are said to be congruent modulo m, abbreviated $a \equiv b \bmod m$. Clearly this is equivalent to saying that $m|a - b$. All integers congruent modulo m to a given integer are considered as forming a residue class modulo m. There are m residue classes.

If $a \equiv b \bmod m$, $(a,m) = (b,m)$. If $(a,m) = 1$ we may therefore say that the residue class of a modulo m is prime to m. Those residue classes which are prime to m are said to form a reduced system of residue classes mod m. For example, if $m = 12$, the reduced system is represented by the four residues 1, 5, 7 and 11.

L. Euler introduced the symbol $\phi(m)$ to denote the number of reduced residue classes mod m, or what is equivalent, the number of positive integers prime to m and not exceeding m. For example, $\phi(1) = 1$, $\phi(p) = p - 1$ for any prime p. One easily proves that $\phi(mn) = \phi(m)\cdot\phi(n)$ if $(m,n) = 1$, and $\phi(p^r) = p^r\left(1 - \frac{1}{p}\right)$ for any prime p and positive integer r. This facilitates the evaluation of $\phi(m)$; *e.g.*, $\phi(12) = \phi(2^2)\cdot\phi(3) = 2\cdot 2 = 4$, as noted earlier.

Let a be prime to m. If $r_1 - r_2$ is not divisible by m, the same is true of $ar_1 - ar_2$. It follows that if $r_1, r_2, \cdots, r_k$ (where $k = \phi(m)$) constitute a reduced residue system mod m, then ar_1, $ar_2, \cdots, ar_k$ comprise the same residues in a different order. Hence the difference of the products $ar_1 . ar_2 . . . ar_k$ and $r_1 r_2 . . . r_k$, which can be written $r_1 r_2 . . . r_k(a^k - 1)$, is divisible by m. Since $r_1 r_2 . . . r_k$ is prime to m, m divides $a^k - 1$.

This result, that $m|a^{\phi(m)} - 1$ if a, m are coprime, is known as Euler's theorem (1760). Fermat's theorem (1640) is the special case for a prime p, $a^{p-1} \equiv 1 \bmod p$ if $(a,p) = 1$.

By the same argument, the m residues ax ($x = 0, 1, \cdots, m-1$) are incongruent mod m, if $(a,m) = 1$; hence the congruence $ax \equiv k \bmod m$ is solvable, for any k. Hence, if $(a,b) = 1$ then for any given integer k there exist integers x, y satisfying $ax + by = k$.

Primitive Roots.—It can be shown that if $(a,m) = 1$, the least positive e such that $a^e \equiv 1 \bmod m$ must divide $\phi(m)$. If $e = \phi(m)$, a is called a primitive root of m; and the powers 1, a, $a^2, \cdots, a^{e-1}$ comprise a reduced set of residues mod m. Primitive roots have importance in various applications involving nth powers; *e.g.*, in solving binomial congruences such as $x^n \equiv k \bmod m$. C. F. Gauss proved that primitive roots exist only when $m = 2, 4, p^h$, or $2p^h$, where p is an odd prime.

3. Congruences in One Unknown.—If $a \equiv b \bmod m$ and $c \equiv d \bmod m$, it is easily seen that $a + c \equiv b + d$, $a - c \equiv b - d$, and $ac \equiv bd \bmod m$. Hence, if $f(x)$ is a sum of terms $a_0 + a_1x + \cdots + a_nx^n$ with integral coefficients, then $f(a) \equiv f(b) \bmod m$, if $a \equiv b \bmod m$. Hence, in searching for solutions (called roots) of the congruence $f(x) \equiv 0 \bmod m$, one can confine oneself to incongruent solutions mod m. The number of roots is the number of incongruent solutions mod m: *e.g.*, $x^3 \equiv 1 \bmod 7$ has precisely three roots, *viz.* $x \equiv 1, 2, 4$.

Let $m_1, m_2, \cdots, m_k$ be k positive integers, coprime in pairs, $m = m_1 \cdots m_k$. A method of solving the k congruences $x \equiv r_1 \bmod m_1, \cdots, x \equiv r_k \bmod m_k$, for an integer x, uniquely determined mod m, was known to the Chinese in the first century A.D., and is called the Chinese remainder theorem. The theorem leads to the result that the number of solutions of $f(x) \equiv 0 \bmod m$ is the product of the numbers of solutions of $f(x) \equiv 0 \bmod m_i$ ($i = 1, \cdots, k$). The search for roots of $f(x) \equiv 0 \bmod m$ can thus always be reduced to the case where m is a power of a prime. In certain cases there is a systematic way of deriving the solutions mod p^{r+1} from those mod p^r.

In the special case $m = p$ there holds an important theorem formulated by J. L. Lagrange (1768). If $(p,a_n) = 1$, the congruence $f(x) \equiv 0 \bmod p$ is said to be of degree n. Lagrange proved that the number of roots of $f(x) \equiv 0 \bmod p$ does not exceed the degree n.

As an application consider, for example, $f(x) = x(x-1)(x-2)\cdots(x-p+1) - (x^p - x)$. This is a polynomial of degree $p - 1$ at most, and $f(x) \equiv 0 \bmod p$ for each of $x = 0, 1, \cdots, p-1$ (by Fermat's theorem). This contradicts Lagrange's theorem unless every coefficient is divisible by p. Hence, the sum of the products n at a time of $1, 2, \cdots, p-1$ is divisible by p if $n \leqq p - 2$; while (by the coefficient of x),

$$1 \cdot 2 \cdot 3 \cdots (p-1) \equiv -1 \pmod p$$

a result known as Wilson's theorem.

Since $x^{p-1} - 1 = (x^{\frac{1}{2}(p-1)} - 1)(x^{\frac{1}{2}(p-1)} + 1)$, then it follows from Fermat's and Lagrange's theorems that each of the congruences $x^{\frac{1}{2}(p-1)} \equiv 1$ and $x^{\frac{1}{2}(p-1)} \equiv -1 \pmod p$ is satisfied by exactly $\frac{1}{2}(p-1)$ residues x mod p. Anticipating the following section, note that if a is any of the $\frac{1}{2}(p-1)$ quadratic residues of p, then $a \equiv x^2$, $a^{\frac{1}{2}(p-1)} \equiv x^{p-1} \equiv 1$. Accordingly, a is a quadratic residue or nonresidue of p according as $a^{\frac{1}{2}(p-1)} \equiv 1$ or $-1 \pmod p$. Putting $a = -1$ we obtain that the congruence $x^2 \equiv -1 \pmod p$ is solvable if $p \equiv 1$, but unsolvable if $p \equiv 3 \pmod 4$.

On pairing factors equidistant from the two ends, Wilson's

theorem gives $(1\cdot 2\cdot 3\cdots \tfrac{1}{2}(p-1))^2 \equiv (-1)^{\frac{1}{2}(p+1)}$ mod p. Hence if p is a prime of the form $4n+3$, $1\cdot 2\cdot 3\cdots \tfrac{1}{2}(p-1) \equiv \pm 1$ mod p. The sign + or − in the last case was investigated by P. G. L. Dirichlet *et al.* Since −1 is a quadratic nonresidue of p, and since the product of an even (odd) number of quadratic nonresidues is a quadratic residue (nonresidue), the sign is $(-1)^m$, where m is the number of quadratic nonresidues in the series $1, \ldots, \tfrac{1}{2}(p-1)$. An interesting expression found for m is $\tfrac{1}{4}(p+1) - \tfrac{1}{2}(1 + h(-p))$, where $h(-p)$ denotes the number of classes of positive, primitive binary quadratic forms of discriminant $-4p$ (see *Binary Quadratic Forms*, below). In particular, it follows that there are more quadratic residues in the first half of the interval from 1 to $p-1$, than in the second half, if p is a prime $4n+3$.

Numerous generalizations of Fermat's and Wilson's theorems have been found. One due to Gauss (1801) is as follows: if P denotes the product of the integers less than and prime to n, then $P \equiv -1$ mod n if n is 4, p^k, or $2p^k$, where p denotes an odd prime; but $P \equiv 1$ mod n otherwise.

4. Quadratic Residues: The Quadratic Reciprocity Law.—A quadratic residue of m is an integer a prime to m such that $x^2 \equiv a$ mod m is solvable for x. Other integers a prime to m are called quadratic nonresidues. Let m be an odd prime p, and consider the squares $1^2, 2^2, \cdots, (p-1)^2$. Since $p|x^2 - y^2$ implies that $p|x-y$ or $x+y$, which can hold (if x, y are distinct numbers of the set $1, 2, \cdots, p-1$) only if $y = p - x$, it is plain that there are exactly $\tfrac{1}{2}(p-1)$ incongruent quadratic residues of p. Example: every square prime to p is of the form $pn + R$, where if $p=3$, $R=1$; if $p=5$, $R=1$ or 4; if $p=11$, $R = 1, 4, 9$, $5(\equiv 4^2)$, or $3(\equiv 5^2)$.

By extensive experiment Euler had found in 1783 a theorem of great simplicity, expressing a deep property of numbers. In 1785 A. M. Legendre rediscovered the same result, which he formulated as follows. Let p and q denote distinct odd primes. Then unless $p \equiv q \equiv 3$ (mod 4) the two congruences $x^2 \equiv p$ (mod q) and $y^2 \equiv q$ (mod p) are both solvable or both unsolvable; but if $p \equiv q \equiv 3$ (mod 4), one and only one of the two congruences is solvable.

Legendre introduced the useful symbol $(a|p)$, defined to equal +1 if a is a quadratic residue of p; −1, if a is a nonresidue; 0, if $p|a$. Then the above result takes the form

$$(p|q)(q|p) = (-1)^{\frac{1}{2}(p-1)\frac{1}{2}(q-1)}$$

for any distinct odd primes p and q. He called this the reciprocity law; but his proof was incomplete. In 1795, Gauss, at the age of 18, discovered the same law, and after a year of strenuous effort found a complete proof. Later he found 6 different proofs; and more than 50 proofs have appeared since.

The result at the end of the preceding section can now be expressed by $a^{\frac{1}{2}(p-1)} \equiv (a|p)$ mod p, true also if $a \equiv 0$. Hence follow the following properties of the Legendre symbol: (1) $(a|p) = (b|p)$ if $a \equiv b$ mod p; (2) $(ab|p) = (a|p)(b|p)$; (3) $(-1|p) = (-1)^{\frac{1}{2}(p-1)}$; and by another device, $(2|p) = 1$ if $p \equiv \pm 1$ mod 8, $(2|p) = -1$ if $p \equiv \pm 3$ mod 8.

The usefulness of the Legendre symbol was increased by K. G. J. Jacobi, who, defining $(a|p_1p_2\cdots p_n) = (a|p_1)(a|p_2)\cdots(a|p_n)$, and $(a|-k) = (a|k)$ if a is positive, found that the reciprocity law still holds for any odd numbers p and q not both negative. Example: determine whether $x^2 \equiv 30$ (mod 71) is solvable; $(30|71) = (2|71)(15|71) = (+1)(-)(71|15) = -(-4|15) = -(-1|15) = +1$; the congruence is solvable (with $x = \pm 32$). Example: of what primes is 3 a quadratic residue? $(3|p) = (-1)^{\frac{1}{2}(3-1)\frac{1}{2}(p-1)}(p|3) = +1$ if $p \equiv 1$ (mod 4 and mod 3), and if $p \equiv -1$ (mod 4 and mod 3); *i.e.*, $p \equiv \pm 1$ mod 12.

Other reciprocity laws have occurred in various generalizations; *e.g.*, one involving complex integers (see *Algebraic Numbers*, below) occurred in Gauss's researches on biquadratic congruences.

5. Factorization of Numbers; Mersenne Primes.—The labour involved in factoring a large number of, say, 20 or more digits is still prohibitive. By expressing the number in special forms, it is possible to obtain limitations on the form of possible prime factors; thus, if $N = x^2 + ky^2$, where $(x, y) = 1$, then $-k$ must be a quadratic residue of each prime factor of N. Factor stencils have been developed to facilitate this process. A machine constructed by D. H. Lehmer ("A Photo Electric Number Sieve," *American Mathematical Monthly*, 40, 1933) makes it possible to test numbers of about 17 digits in a few hours.

The best table of primes is D. N. Lehmer's *List of Prime Numbers from 1 to 10,006,721* (Carnegie Institution of Washington, D.C., 165, 1914), republished in 1956.

Perfect numbers owe their beginning to the number mysticism of the Pythagoreans (500 B.C.). A perfect number is an integer equal to the sum of its divisors less than itself. The five least are: $6(=1+2+3)$; 28; 496; 8,128; 33,550,336. Euclid gave the example $2^{p-1}(2^p - 1)$, which is perfect if and only if $2^p - 1$ is a prime.

All even perfect numbers are of Euclid's type (Euler). No odd perfect number has ever been found.

Numbers of the form $2^p - 1$ are called Mersenne numbers, because in 1644 Father Marin Mersenne made a statement which implied that if $p \leq 257$, $2^p - 1$ is prime only for $p = 2, 3, 5, 7, 13, 17, 19, 31, 67, 127, 257$. Subsequent work has yielded the following results: $2^p - 1$ is known to be prime for $p = 2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127$; its factors are completely known for $p = 11, 23, 29, 37, 41, 43, 47, 53, 59, 67, 71, 73, 79, 113$, and partially known for $p = 83, 97, 131, 151, 163, 167, 173, 179, 181, 191, 197, 211, 223, 229, 233, 239, 251$; it has been proved composite for $p = 101, 103, 109, 137, 139, 149, 157, 199, 193$ and 227 (H. S. Uhler, 1948–49), 241 (R. E. Powers, 1934), 257 (M. Kraitchik and D. H. Lehmer, 1932). Several primes larger than $2^{127} - 1$ (E. Lucas, 1876) were found in 1951. The national bureau of standards Western Automatic computer gave, in 1952, the five next Mersenne primes $2^p - 1$ ($p = 521, 607, 1{,}279, 2{,}203, 2{,}281$).

The ancient Greeks knew that regular polygons of 2^hm sides, where $m = 3$ or 5, can be constructed by the Euclidean (straightedge and circle) operations. Gauss, at the age of 17, proved that these constructions are so performable if and only if m is a product of distinct Fermat primes, *i.e.*, primes that are of the form $F_n = 2^{2^n} + 1$. If $n = 0, 1, 2, 3, 4$, we get the primes 3, 5, 17, 257, 65,537. But F_n is composite for $n = 5, 6, 7, 8, 9, 11, 12, 18, 23, 36, 38, 73$.

II. REPRESENTATION BY FORMS

1. Binary Quadratic Forms.—Many special quadratic forms, such as $x^2 \pm ay^2$ or $x^2 + y^2 + z^2$, had been investigated by particular methods, before Lagrange and (especially) Gauss systematized their theory, and established general methods of attack. The guiding general principle was the linear transformation.

Consider for example a form in two variables and of the second degree (*i.e.*, a binary quadratic form) $f = ax^2 + bxy + cy^2$. A number m is said to be represented by the form f if there exists a pair of integers u, v not both zero (called a representation of m by f) satisfying $au^2 + buv + cv^2 = m$. The representation is called primitive if the g.c.d. (u, v) is 1. We shall give a version of Gauss's method of finding whether a number m is represented by f.

The basic idea is that we treat not f alone, but an entire class of forms equivalent, for this purpose, to f. If we apply to f a linear transformation

$$x = \alpha X + \beta Y, \; y = \gamma X + \delta Y \qquad (1)$$

f is transformed into $F = AX^2 + BXY + CY^2$ in new variables X and Y, while $A = a\alpha^2 + b\alpha\gamma + c\gamma^2$, etc. On solving equations (1) for X and Y, we find

$$(\alpha\delta - \beta\gamma)X = \delta x - \beta y, \; (\alpha\delta - \beta\gamma)Y = -\gamma x + \alpha y$$

Hence, in order to ensure that to each pair of integers x and y corresponds one and only one pair of integers X and Y (and conversely), we shall assume that the transformations which we apply are unimodular, that is, $\alpha, \beta, \gamma, \delta$ are integers, and $\alpha\delta - \beta\gamma = 1$. Clearly the same numbers m are then represented by both forms f and F, and any representation x, y of m in f corresponds uniquely to the representation $X = \delta x - \beta y$, $Y = -\gamma x + \alpha y$ of m in F.

The forms f and F, related by a unimodular transformation, are termed equivalent. The result of applying several unimodular transformations in succession is easily seen to be another unimodular transformation, called their product. All forms equivalent to a given one are equivalent to one another, and are said to constitute a class of forms.

If $A = a\alpha^2 + b\alpha\gamma + c\gamma^2$ where $(\alpha, \gamma) = 1$, then by section 2 we can choose integers β and δ such that $\alpha\delta - \beta\gamma = 1$. Consequently, any number A represented primitively by f is the first coefficient of some form $AX^2 + BXY + CY^2$ equivalent to f. It can be shown that if β, δ is one solution of $\alpha\delta - \beta\gamma = 1$, the most general solution is $\beta + k\alpha$, $\delta + k\gamma$, where k is any integer; and that B is then replaced by $B + 2kA$.

The determinant of the form f is defined to be the number $d = ac - \frac{1}{4}b^2$. It can be shown that the determinants of equivalent forms are equal. (*See* ALGEBRAIC GEOMETRY; TENSOR ALGEBRA.)

The last result holds also for quadratic forms in n variables. We shall later use the terms determinant, class, representation, etc., for such forms, to which these terms can be extended in an obvious way. If a quadratic form f is written in the form $\sum a_{ij}x_ix_j$ (summed for $i, j = 1, \cdots, n$), one can always suppose that $a_{ji} = a_{ij}$, and the determinant of f is the determinant $|a_{ij}|$. (*See* DETERMINANT.)

So far, a, b, c may denote any real numbers. We have $af = (ax + \frac{1}{2}by)^2 + dy^2$. Hence if $d > 0$, $a \neq 0$, and af is positive for any x and y not both zero; accordingly, f represents only numbers of one sign, that of a. But if $d < 0$, f represents both positive and negative numbers. If $d > 0$, we call f definite, specifically, positive-definite if also $a > 0$; if $d < 0$, f is called indefinite.

The treatment of definite and indefinite forms now diverges. It is easily shown that any positive-definite form is equivalent to precisely one form $Ax^2 + Bxy + Cy^2$ satisfying

$$-A < B \leqq A \leqq C, \text{ with } B \geqq 0 \text{ if } C = A \qquad (2)$$

This form is called the reduced form in the class. We illustrate the process of reduction with the form $f = 15x^2 - 44xy + 33y^2$ of determinant $495 - 22^2 = 11$. Put $x = x_1 + ky_1$, $y = y_1$. Then f becomes $15x_1^2 + (-44 + 30k)x_1y_1 + (\cdots)y_1^2$; to get $-44 + 30k$ between -15 and $+15$ take $k = 1$, $f_1 = 15x_1^2 - 14x_1y_1 + c_1y_1^2$; here $c_1 = 4$ since $15c_1 - 49 = 11$. Now treat similarly the smaller coefficient c_1, and replace x_1 by x_2, y_1 by $2x_2 + y_2$, obtaining $f_2 = 3x_2^2 + 2x_2y_2 + 4y_2^2$, which is reduced. The result of combining the transformations is $x = 3x_2 + y_2$, $y = 2x_2 + y_2$, which transforms f directly into f_2.

Hereafter we assume f integral; *i.e.*, a, b, c are integers. The g.c.d. of a, b, c is called the divisor of f. If this g.c.d. is 1, f is called primitive. To avoid fractions write $D = -4d = b^2 - 4ac$, called the discriminant of f.

We prove in the case D negative that there are only a finite number of classes of integral, positive-definite, binary quadratic forms of a given discriminant $D = -\Delta$. This number is equal to the number of reduced forms satisfying (2), with $4AC = \Delta + B^2$. By (2), $4A^2 \leqq 4AC = \Delta + B^2 \leqq \Delta + A^2$, whence

$$A^2 \leqq \frac{\Delta}{3}, \text{ and } B^2 \leqq \frac{\Delta}{3}$$

To find all reduced forms of discriminant $-\Delta$ we may proceed as follows. Give B in turn each integer value such that

$$B^2 \leqq \frac{\Delta}{3} \text{ and } 4 \mid \Delta + B^2$$

factor $\frac{1}{4}(\Delta + B^2)$ as AC in all ways satisfying $|B| \leqq A \leqq C$. Discard forms such that $B = -A$ or such that $C = A$, $B < 0$.

The number of classes of primitive, positive-definite, binary quadratic forms of discriminant D will be denoted by $h(D)$.

Example: Find the reduced forms of discriminant -44. Necessarily $B = 2b$, $b^2 \leqq \frac{11}{3}$. If $b = 0$, $\frac{1}{4}(44 + B^2) = 11 = 1 \cdot 11$; if $b = \pm 1$, $\frac{1}{4}(44 + B^2) = 12 = 2 \cdot 6 = 3 \cdot 4$. This yields four reduced forms: $x^2 + 11y^2$, $3x^2 \pm 2xy + 4y^2$, $2x^2 + 2xy + 6y^2$. The last is imprimitive, with divisor 2; hence $h(-44) = 3$.

The reader can verify that $h(D) = 1$ in the twelve cases

$$-D = 3, 4, 7, 8, 11, 12, 19, 27, 28, 43, 67, 163 \qquad (3)$$

the reduced form being $x^2 + xy + \frac{1}{4}(1 - D)y^2$ or $x^2 - \frac{1}{4}Dy^2$.

An automorph of f is a unimodular transformation carrying f into itself. Every f has the trivial automorph $x = x_1$, $y = y_1$, and its negative $x = -x_1$, $y = -y_1$. The form $a(x^2 + y^2)$ has the additional automorphs $x = y_1$, $y = -x_1$; and its negative. The form $a(x^2 + xy + y^2)$ has six automorphs, of which $x = x_1 + y_1$, $y = -x_1$, is typical. All positive-definite forms not equivalent to these two have only the two trivial automorphs. It is easily proved that all the unimodular transformations carrying f into F are obtained by applying to f any automorph of f, followed by a fixed unimodular transformation of f into F.

We can now solve the problem of finding all primitive representations of A by f in the following manner, which applies equally well to indefinite forms (see *Automorphs and Reduction of Indefinite Binary Quadratic Forms*, below). We noted above that to each primitive representation (α, γ) of A by f corresponds a form $Ax^2 + Bxy + Cy^2$ equivalent to f, where B is uniquely determined mod $2A$. Equating discriminants, $B^2 - 4AC = D$. Hence we start by finding all solutions B of

$$B^2 \equiv D(\text{mod } 4A),\ 0 \leqq B < 2|A| \qquad (4)$$

For each such B construct the form

$$Ax^2 + Bxy + \left(\frac{(B^2 - D)}{4A}\right)y^2 = F_B$$

By reducing both f and F_B to reduced forms we determine whether f is equivalent to F_B, and if so can construct all unimodular transformations carrying f into F_B. The coefficients α, γ of these transformations give all the primitive representations of A by f. Different solutions B of (4) cannot yield the same representation.

Example: Find all representations of 15 by $f = 3x^2 + 2xy + 4y^2$. The solutions of $B^2 \equiv -44 \pmod{60}$, $0 \leqq B < 30$, are $B = 4, 14, 16, 26$. If $B = 4$, $F = 15x^2 + 4xy + y^2$, which is equivalent to $x_1^2 + 11y_1^2$ under the transformation $x_1 = 2x + y$, $y_1 = -x$; the corresponding representations in $x_1^2 + 11y_1^2$ are therefore $2, -1$ and $-2, +1$. Similarly, $B = 26$ yields $2, 1$ and $-2, -1$ in $x_1^2 + 11y_1^2$. If $B = -14$, $F = 15x^2 - 14xy + 4y^2$, and we find the representations $1, -2$ and $-1, 2$ in f; $B = 16$ yields similar representations in $3x^2 - 2xy + 4y^2$. Thus there are eight representations of 15 in the system of three reduced forms, two of them in f.

By a set of representations of A in f, we mean the set obtained from a given representation by applying the automorphs of f. This has a meaning even in the indefinite case when the number of automorphs may be infinite. The preceding process proves the following important result formulated by Dirichlet which holds equally true when f is indefinite.

Theorem: The number of sets of primitive representations of an integer A by the system (one form from each class) of binary quadratic forms of a given discriminant D is equal to the number of solutions of (4).

In a large number of special cases, this theorem provides immediate information on the number of representations in single forms. This is obviously true in the 12 cases in (3). For example, taking $D = -4$, we obtain the following result: a positive integer A is represented primitively as a sum of two squares if and only if A contains no prime factor of the form $4n + 3$ and A is not divisible by 4; and then the number of representations is $4 \cdot 2^k$, where k denotes the number of distinct prime factors of A of the form $4n + 1$.

By counting the primitive representations of $\frac{A}{s^2}$, for square factors s^2 of A, various formulas are obtainable for the number of sets of all representations by the system of reduced forms of discriminant D; one such formula, in the special case

$$(A, 2D) = 1, \text{ is } \sum_{k|A} (D|k)$$

i.e., the sum of the Legendre symbols $(D|k)$ for all the positive divisors k of A. Thus, in particular, the only positive integers A not represented by $x^2 + y^2$ are those containing a prime factor

$4n + 3$ to an odd power; while, if $A = 2^s p_1^{a_1} \cdots p_r^{a_r} t^2$, where the r ($\geqq 0$) distinct primes p_i are of the form $4n + 1$, and no prime in t is of that form, then the number of all representations of A as $x^2 + y^2$ is $4(a_1 + 1) \cdots (a_r + 1)$.

2. Genera of Quadratic Forms; Formulas for Number of Representations.—The last theorem provides a general formula for the number of representations of a number by a system of several classes of forms. A smaller system of great importance, of which many general properties are known is the genus.

A natural approach to the notion of genus may be derived from the following observations. If an integral form say $f = ax^2 + bxy + cy^2$, represents a number A, say $f(u, v) = A$, then obviously the congruence $f \equiv A \bmod m$ is solvable (with $x = u$, $y = v$) whatever be the modulus m. However, $2x^2 + 7y^2 \equiv 1$ (mod p^r) is solvable for every prime p and positive r, and hence solvable for every m; *e.g.*, with $3x \equiv 1$, $3y \equiv 1$, if $p \neq 3$, with $5x \equiv 3$, $5y \equiv 1$, if $p \neq 5$. But $2x^2 + 7y^2$ does not represent 1. The situation here is that there is associated with $2x^2 + 7y^2$ another class of forms, that of $x^2 + 14y^2$, which while not equivalent to $2x^2 + 7y^2$, is "equivalent to it for all congruencial purposes." And $x^2 + 14y^2$ does represent 1. The two classes, represented by $x^2 + 14y^2$ and $2x^2 + 7y^2$, happen to constitute a genus. As yet another example, $x^2 + y^2$ happens to be in a genus of one class, and $x^2 + y^2$ represents a positive integer A if and only if the congruence $x^2 + y^2 \equiv A \bmod m$ is solvable, for all m.

We shall call two integral forms equivalent in the field of reals if each is transformable into the other by linear transformations with real coefficients; *e.g.*, if $n = 2$, both must be positive-definite, both negative-definite, or both indefinite. Two forms are defined to be in the same genus if they have the same determinant d, are equivalent in the field of reals, and if for every modulus m (the modulus $2^n d$ being in fact sufficient) each is equivalent to a form whose coefficients are congruent mod m to the corresponding coefficients of the other.

There are several other sets of properties which distinguish a genus. Two quadratic forms in n variables are in the same genus if and only if they have the same determinant d and there exists a linear transformation, whose coefficients are rational numbers with denominators prime to $2^n d$, transforming one form into the other. For example, $2x^2 + 7y^2$ is carried into $x_1^2 + 14y_1^2$ by the transformation

$$x = \frac{(x_1 + 7y_1)}{3}, y = \frac{(x_1 - 2y_1)}{3}$$

The proof of the necessity of this criterion was completed for $n > 3$ only in 1940 by C. L. Siegel.

Historically speaking, genera have usually been characterized by means of sets of (more or less) easily computable invariants; Gauss (1801, $n = 2$), F. G. Eisenstein (1847, $n = 3$), H. J. S. Smith (1867, $n \geqq 3$), H. Minkowski (1884), B. W. Jones and G. Pall (1944). The most important of these are illustrated in the following section for $n = 3$.

Equivalent forms are in the same genus. A genus consists of a finite number of classes. If $n \geqq 4$, indefinite forms are in genera of one class; this is true also if $n = 3$, save in certain exceptional cases. It is probable that there are only finitely many classes of primitive, positive-definite forms in genera of one class; there are none in more than 35 variables (W. Magnus, 1938), and probably none in more than 10 variables. As an example, the three primitive forms of discriminant -44, preceding (3) in the above section on *Binary Quadratic Forms*, constitute a genus of three classes. The form $x_1^2 + \cdots + x_n^2$ is in a genus of one class only if $1 \leqq n \leqq 8$.

Some writers prefer to define class by the use of transformations of determinant ± 1, instead of Gauss's $+1$. Perhaps the main reason for preferring $+1$ is the following theorem formulated by Gauss: every genus of primitive, binary, quadratic forms of discriminant D contains the same number of classes. The situation if $n \geqq 3$ is somewhat different.

Consider a genus of primitive forms in $n(\geqq 2)$ variables. We assume the forms to be positive-definite, while mentioning that Siegel (1936), employing a suitable meaning for sets of representations, has extended the results which follow to indefinite forms. Let h denote the number of classes in the genus, and select one form $f_i (i = 1, \cdots, h)$ from each class. Let w_i denote the number of automorphs of f_i. The quantity

$$\frac{1}{w_1} + \cdots + \frac{1}{w_h}$$

is called the weight of the genus. A remarkable formula for this was suggested for $n = 3$ by Eisenstein, and was proved and generalized to any n by H. J. S. Smith (1867) and Minkowski (1884). Further, under certain restrictions, the total number of primitive representations of an integer m by the system of forms f_i of a genus was shown to be equal to the weights of certain related genera.

These results were generalized in 1935 by Siegel, to yield a formula for the numbers of representations (suitably weighted) of forms in k variables by a genus of forms in n variables; the case $k = 1$ is that of representation of numbers stated in the following paragraph.

Let $f_i(A)$ equal the number of representations of A by f_i. Then

$$\frac{\dfrac{f_1(A)}{w_1} + \cdots + \dfrac{f_h(A)}{w_h}}{\dfrac{1}{w_1} + \cdots + \dfrac{1}{w_h}} = \frac{\pi^{\frac{1}{2}n} A^{\frac{1}{2}n-1} S(A)}{\Gamma(\frac{1}{2}n) \cdot d^{\frac{1}{2}}} \tag{1}$$

where d denotes the determinant of f, $\Gamma(\frac{1}{2}n)$ is the well-known gamma-function (for which $\Gamma(m) = 1 \cdot 2 \cdot 3 \cdots (m - 1)$ if m is a positive integer), $S(A)$ denotes the product extended over all primes p, $S(A) = \chi(2) \cdot \chi(3) \cdot \chi(5) \cdot \chi(7) \cdots$ where

$$\chi(p) = \lim_{r \to \infty} p^{-(n-1)r} f(A, p^r)$$

while $f(A, p^r)$ (which can be evaluated by various methods) denotes the number of solutions of the congruence $f \equiv A$ (mod p^r). This general expression simplifies remarkably when n is even, and provides a neat formula for the number of representations of an integer A by a genus; hence by a form if the genus consists of one class.

We select several examples. Let $r_n(A)$ denote the number of representations of A as a sum of n squares. For example, $r_4(13) = 112$, since $13 = 3^2 + 2^2 + 0^2 + 0^2 = 2^2 + 2^2 + 2^2 + 1^2$, and we can permute and change signs of 3, 2, 0, 0 in 48 ways, of 2, 2, 2, 1 in 64 ways. Set $A = 2^k m$, m odd, $k \geqq 0$. If $n = 2, 4, 6, 8$ (when the genus of $x_1^2 + \cdots + x_n^2$ consists of one class), $r_n(A)$ has the following expressions in terms of the positive divisors d of m:

$$r_2(A) = 4 \sum_{d|m} (-1)^{(d-1)/2}$$

$$r_6(A) = 4\{(-1)^{(m-1)/2} 4^{k+1} - 1\} \sum_{d|m} (-1)^{(d-1)/2} d^2$$

$$r_4(A) = 8\{2 + (-1)^A\} \sum_{d|m} d$$

$$r_8(A) = \frac{16}{7} |8^{k+1} - 15| \sum_{d|m} d^3$$

Similar expressions have been obtained for many other forms in genera of one class; and for special forms of A by forms in genera of more than one class. For example, if A is of the form $4r + 3$, $r_{10}(A) = 12 \sum (-1)^{(d+1)/2} d^4$, and if A is even there is a simple expression for $r_{12}(A)$.

The formula for $r_4(A)$ was first obtained in 1828 by K. G. J. Jacobi, by equating coefficients in the expansions of certain elliptic functions. In a series of 18 articles (1858–65), J. Liouville stated without proof several identities and derived from them expressions for the number of representations by numerous quadratic forms.

The proofs of these identities are elementary, although as shown by E. T. Bell, many can be paraphrased from elliptic function identities by replacing sine and cosine terms by more general odd and even functions.

As an example we quote one of Uspensky's identities. Let $F(x, y, z)$ denote a function odd with respect to x, and even with

respect to y, z; *i.e.*, $F(-x, y, z) = -F(x, y, z)$ and $F(x, -y, -z) = F(x, y, z)$. Then $2\sum F(\delta - 2i, d + i, 2d + 2i - \delta) = \sum F(d + \delta, i, d - \delta) + 2T - U$ where the summations extend over all integral solutions of $n = i^2 + d\delta$, with d and δ positive. Both T and U are zero unless $n = s^2 (s > 0)$, in which case

$$T = \sum_{j=1}^{2s-1} F(2s - j, s, 2s - j),\ U = \sum_{j=1}^{2s-1} F(2s, j - s, 2j - 2s)$$

By various specializations of this formula, James Victor Uspensky obtained a large number of expressions for the numbers of representations by quadratic forms in two, four, six, eight, and ten variables; and all the known and certain new relations connecting binary quadratic class numbers for various determinants.

H. D. Kloosterman and V. Tartakowsky showed, about 1924, that (1) gives an asymptotic formula for the number of representations by a single form f_i, if $n \geq 4$. (See *Distribution of Primes. Asymptotic Formulas*, below.)

3. The Numbers Represented by a Quadratic Form; Universal Forms; Representation of Zero.—We shall make certain observations about the numbers represented by an integral quadratic form. As we implied earlier, a genus has the property that if $f \equiv A$ mod m is solvable for every m, and if A has the necessary sign when f is positive- or negative-definite, then some form in the genus of f represents A. For example, the two forms $f = x^2 + y^2 + 10z^2$ and $g = 2x^2 + 2y^2 - 2yz + 3z^2$ are representative of the two classes of a certain genus of determinant 10. It is easily proved that $f \equiv A$ mod p^r is solvable for every A and p, except when $p = 2$, r is large enough, and A is of the form $4^h(16k + 6)$. Hence f and g represent between them all positive integers not of the form $4^h(16k + 6)$. It might be supposed that f and g would each represent all large numbers not of the excluded form. It is easily proved that f represents all even numbers not of the excluded form; and Hansraj Gupta (1941) stated the odd numbers up to 20,000 not represented by f: 3, 7, 21, 31, 33, 43, 67, 79, 87, 133, 217, 219, 223, 253, 307, 391, 679, 2,719. But examples exist of two ternary classes in the same genus which do not represent the same large numbers.

In any case, if the genus of f consists of one class, the numbers represented by f can be determined by investigating the solvability of the congruences $f \equiv A$ (mod p^r). In this way we find that $x^2 + y^2 + z^2$ represents all positive integers not of the form $4^h(8k + 7)$, and that $x^2 + y^2 + z^2 + t^2$ represents all positive integers.

Tartakowsky (1925) showed that each class of positive-definite forms in five or more variables represents all the large numbers represented by its genus. This is not quite always true when $n = 4$, but the exceptions are known. It is definitely false (except in the trivial case of improperly equivalent forms such as $3x^2 \pm 2xy + 4y^2$) for binaries.

A quadratic form is called universal if it is positive-definite and represents all positive integers, or indefinite and represents all nonzero integers. Every universal binary is equivalent to xy. Every universal ternary with even cross-product coefficients was shown by L. E. Dickson to be equivalent to $2xy - Hz^2$ (H odd) or $2xy + y^2 - Hz^2$ ($H \equiv 2$ mod 4); if any cross-product coefficient is odd, A. Oppenheim showed it to be equivalent to $xy - Hz^2$. Srinivasa Ramanujan (1917) examined the forms $ax^2 + by^2 + cz^2 + dt^2$, where a, b, c, d are positive integers, $a \leqq b \leqq c \leqq d$; he found at most 54 such forms which may represent all positive integers. Dickson completed the proof of their universality in 1927. A complete proof, including forms with odd cross products, that there are only finitely many classes of positive-definite, universal quaternaries, was first given by A. E. Ross. Dickson proved that every universal ternary is a zero form.

A zero form is a form which represents zero for values of its variables not all zero. The theorem that every indefinite form in five or more variables is a zero form was formulated by A. Meyer (1884). Trivially, a binary form is a zero form if and only if its discriminant is a square. We shall suppose a ternary or quaternary to have been transformed into the form $f_3 = a_1x_1^2 + a_2x_2^2 + a_3x_3^2$ or $f_4 = a_1x_1^2 + a_2x_2^2 + a_3x_3^2 + a_4x_4^2$, and shall formulate necessary and sufficient conditions for such a form to represent zero. The symbol $(a, b)_p$ may be defined (see *Quadratic Residues*, above) as follows, by writing $a = p^\alpha m$, $b = p^{\alpha'} m'$ where m and m' are prime to p, and α, α' are integers:

$$\text{if } p > 2,\ (a, b)_p = (-1|p)^{\alpha\alpha'}(m|p)^{\alpha'}(m'|p)^{\alpha}$$
$$\text{if } p = 2,\ (a, b)_2 = (-1)^{(m-1)(m'-1)/4}(2|m)^{\alpha'}(2|m')^{\alpha}$$

The conditions are expressed in terms of the characters

$$c_p(f_3) = (-a_1a_2, -a_1a_3)_p,\ c_p(f_4) = (a_1, a_2)_p(-a_3, -a_4)_p$$

The former is an invariant of f_3 under rational linear transformations. The latter is needed for our present purpose only when $a_1a_2a_3a_4$ is of the form s^2k, where k is a quadratic residue mod p^r, *i.e.*, $(k|p) = 1$ if $p > 2$, $k \equiv 1$ mod 8 if $p = 2$. Evidently, $c_p(f_3) = 1$ unless $p | 2a_1a_2a_3$. We state finally: f_3 is a zero form if and only if $c_p(f_3) = 1$ for every p; f_4 is a zero form if and only if $c_p(f_4) = 1$ for every prime p such that $a_1a_2a_3a_4$ is of the above-specified form.

The theory of quadratic forms in rational coefficients, and for rational values of the variables, is much simpler than that in the domain of integers; attention should be drawn to Hasse's elegant development of this theory in the *Journal für Mathematik* for 1923.

4. Automorphs and Reduction of Indefinite Binary Quadratic Forms.—Any real, irrational number θ can be expanded into a continued fraction

$$a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cdots}},\ \text{abbreviated } a_0 + \frac{1}{a_1 +}\ \frac{1}{a_2 +} \cdots$$

where the a_i are integers, and $a_1, a_2, \ldots$ positive. Indeed, we can write

$$\theta = a_0 + \frac{1}{b_1}$$

where a_0 is an integer and $b_1 > 1$; then write

$$b_1 = a_1 + \frac{1}{b_2}$$

where a_1 is a positive integer and $b_2 > 1$; and so on. Since θ is irrational, the process cannot terminate. The rational fraction

$$\frac{p_n}{q_n} = a_0 + \frac{1}{a_1 +}\ \frac{1}{a_2 +} \cdots \frac{1}{a_n}, (p_n, q_n) = 1, q_n > 0$$

obtained by stopping at a_n, is called the nth convergent to θ. It can be proved that

$$\left|\theta - \frac{p_n}{q_n}\right| < \frac{1}{q_n^2};\ \text{and that } \frac{p_n}{q_n}$$

is a closer approximation to θ than any other rational fraction with denominator not exceeding q_n.

Lagrange observed that the continued fraction is periodic if and only if θ is a root of a quadratic equation of the type $a - b\theta + c\theta^2 = 0$, where a, b, c are integers. Here

$$\theta = \frac{(b + r)}{(2c)}$$

where $r^2 = D = b^2 - 4ac$. As a typical example, consider $a = 40$, $b = -45$, $c = 12$, $D = 105$. Then

$$\theta = \frac{(-45 + r)}{24} = -2 + \frac{(3 + r)}{24},\ b_1 = \frac{24}{(r + 3)} = \frac{(r - 3)}{4} = 1 + \frac{(r - 7)}{4}$$
$$b_2 = \frac{4}{(r - 7)} = \frac{(r + 7)}{14} = 1 + \frac{(r - 7)}{14},\ b_3 = \frac{14}{(r - 7)} = \frac{(r + 7)}{4} = 4 + \frac{(r - 9)}{4}$$
$$b_4 = \frac{4}{(r - 9)} = \frac{(r + 9)}{6} = 3 + \frac{(r - 9)}{6},\ b_5 = \frac{6}{(r - 9)} = \frac{(r + 9)}{4} = 4 + \frac{(r - 7)}{4}$$
$$b_6 = \frac{4}{(r - 7)} = b_2$$

Hereafter, the period $b_2, \cdots, b_5$ recurs.

The preceding discussion should help to explain Gauss's method of reduction of binary quadratic forms of a positive non-square discriminant D. Instead of a single reduced form (as in the case $D < 0$), each class contains a chain of reduced forms. In the case of $f = 40x^2 - 45xy + 12y^2$ this chain consists of the

forms $\phi_1 = -2x^2 + 7xy + 7y^2$, $\phi_2 = 7x^2 + 7xy - 2y^2$, $\phi_3 = -2x^2 + 9xy + 3y^2$, $\phi_4 = 3x^2 + 9xy - 2y^2$. These correspond to the period of the recurring continued fraction above, and can be obtained from f by applying in order the following unimodular transformations:

$x \to -y$, $y \to x - 2y$, to get $12x^2 - 3xy - 2y^2$ (not yet reduced); to the latter form, $x \to -y$, $y \to x - y$ to get ϕ_1; then, $x \to -y$, $y \to x + y$, ϕ_2; $x \to -y$, $y \to x - 4y$, ϕ_3; $x \to -y$, $y \to x + 3y$, ϕ_4; $x \to -y$, $y \to x - 4y$, giving $\phi_5 = \phi_1$; etc. In general, $ax^2 + bxy + cy^2$ is reduced if and only if $ac < 0$, $b > 0$, $0 < r - b < 2|a| < r + b$, where $r = \sqrt{D}$.

To complete the theory given under *Binary Quadratic Forms*, above, we observe that all the automorphs of a primitive form $ax^2 + bxy + cy^2$ of discriminant D are given by

$$x = \tfrac{1}{2}(t - bu)X - cuY,\ y = auX + \tfrac{1}{2}(t + bu)Y$$

where t, u range over all integral solutions of Fermat's equation (usually called Pell's equation), $t^2 - Du^2 = 4$. If D is a positive nonsquare integer, Fermat's equation can be shown to have a least solution T, U in positive integers (which can be found from a single period of the continued fraction for $\sqrt{D}$), and all integral solutions t, u are given by

$$\tfrac{1}{2}(t + u\sqrt{D}) = \pm\left(\tfrac{1}{2}(T \pm U\sqrt{D})\right)^k,\ k = 0, 1, 2, \cdots$$

I. Schur (1918) showed that $\frac{1}{2}(T + U\sqrt{D}) < D^e$, with $e = D^{\frac{1}{2}}$.

5. Diophantine Equations.—Diophantus of Alexandria (250 A.D.) was the first to treat systematically the solutions of equations or systems of equations in integral (or sometimes in rational) values of the unknowns. Such problems are called after his name. Infallible methods are available only for a few special cases, such as a system of linear equations, or a single quadratic equation. For a fuller discussion, *see* DIOPHANTINE EQUATIONS; FERMAT'S LAST THEOREM.

We noticed in the preceding section that if D is any positive integer (not a square), then $x^2 - Dy^2 = 1$ has infinitely many integral solutions. An important theorem of A. Thue and C. L. Siegel shows that on the contrary, if $f(x, y)$ is of degree $\geqq 3$ (and is not a power of a linear or quadratic function), and if c is a given nonzero number, then $f(x, y) = c$ has at most a finite number of integral solutions.

III. TOPICS IN ANALYTIC NUMBER THEORY

1. Gauss's Class-number Conjecture.—*The Riemann Zeta Function Conjecture.*—We saw under *Binary Quadratic Forms* above that the number $h(D)$ of classes of primitive binary quadratic forms of discriminant D is finite, and noted 12 negative discriminants for which $h(D) = 1$. No other negative D satisfying $h(D) = 1$ has ever been found. L. E. Dickson showed in 1922 that there are no others up to $-D = 15.10^6$, and D. H. Lehmer carried this in 1933 to -5.10^9. In 1934, H. Heilbronn and E. H. Linfoot proved that at most one other negative D exists satisfying $h(D) = 1$.

On the other hand, if D is positive, the tables show numerous values of D such that $h(D) = 1$, and indeed Dirichlet showed that there are infinitely many positive integers D with this property.

In *Disquisitiones arithmeticae* (1801), art. 303, will be found Gauss's conjecture that, as D tends to infinity through negative values, $h(D)$ tends to infinity. This conjecture was first proved by Heilbronn in 1934. Some of the developments preceding and following Heilbronn's proof are of interest. The analytic tools used in proving this and later results to be described began their development in the 19th century. P. G. L. Dirichlet, who called his great memoir of 1839, "Diverse Applications of Infinitesimal Calculus to Number Theory," is generally regarded as the founder of analytic number theory. After Dirichlet, it was G. F. B. Riemann who made the most fundamental advance.

The Riemann zeta function which was his invention may be defined by means of the series

$$\zeta(s) = 1 + \frac{1}{2^s} + \frac{1}{3^s} + \frac{1}{4^s} + \cdots$$

Here s is a complex variable, taking values of type $s = \sigma + it$, where σ and t are real numbers, and $i^2 = -1$. The series is convergent only if $\sigma > 1$, but determines by a process known as analytic continuation, a function defined and "regular" for all complex values s, except that it has a pole (a kind of infinity) at the point $s = 1$. A great deal is known about this function today. Riemann, in 1859, knew that $\zeta(s) = 0$ if s is any negative even integer, and that all the remaining zeros of $\zeta(s)$ satisfy $0 < \sigma < 1$ and lie symmetrically about the straight lines $\sigma = \frac{1}{2}$ and $t = 0$. Riemann conjectured that all these "nontrivial" zeros of $\zeta(s)$ lie on the straight line $\sigma = \frac{1}{2}$. In the 1960s it was unknown whether this was true or false.

It may be mentioned that G. H. Hardy proved that there are infinitely many zeros on the line $\sigma = \frac{1}{2}$, and that E. C. Titchmarsh has located all zeros up to $t = 200$.

The Riemann zeta function conjecture poses one of the most significant unsolved problems of modern mathematics. A conjecture similar to Riemann's can be made for a somewhat more general set of functions,

$$L(s, \chi) = \sum_{n=1}^{\infty} \frac{\chi(n)}{n^s}$$

known as the Dirichlet L-functions. We will not describe the $\chi(n)$, except to say that they are called characters, and have values ± 1 or 0 or roots of unity. The conjecture that there are no zeros of the L-functions with real part $\sigma > \frac{1}{2}$ is known as the Generalized Riemann Hypothesis (G.R.H.).

These conjectures are connected with several interesting questions. It seemed to be important to deduce results by assuming the truth of the G.R.H., in the hope that they might throw some light on the subject. For example, Hardy and J. E. Littlewood proved in 1923 on the basis of the G.R.H. slightly modified, that every sufficiently large odd number is equal to the sum of three odd prime numbers (see *The Goldbach Problem*, below). Again, in 1913, E. Hecke proved that if the G.R.H. holds true for all real-valued characters χ, then Gauss's conjecture about $h(D)$ follows. These results did not prove that every large odd number is the sum of three primes, or that $h(D)$ tends to infinity, but they have an interesting aftermath. In the case of Hecke's result the climax came in 1934. M. Deuring proved in 1933 that if $\zeta(s)$ has at least one zero with real part greater than $\frac{1}{2}$, then $h(D) = 1$ for only a finite number of negative discriminants D, and this was soon followed by the theorem of Heilbronn and Linfoot mentioned earlier. Then L. J. Mordell proved in 1934 that if $\zeta(s)$ has at least one zero with real part greater than $\frac{1}{2}$ then $h(D)$ tends to infinity. Finally, Heilbronn proved in 1934 that if there exists at least one real character χ for which $L(s) = 0$ for a value s with $\sigma > \frac{1}{2}$, then $h(D)$ tends to infinity. Thus by Hecke's work, Gauss's conjecture is correct if the Riemann hypothesis is true for all real characters χ; and by Heilbronn's work, Gauss's conjecture follows if the Riemann hypothesis for real characters χ is false.

It follows that Gauss's conjecture is true, but nothing can be concluded about the truth of the Riemann hypothesis itself. In passing, it should be mentioned that S. Chowla immediately revised Heilbronn's proof to make it independent of Hecke's work. C. L. Siegel immediately followed with a brief proof that

$$\frac{\log h(D)}{\log |D|} \to \tfrac{1}{2} \text{ as } D \to -\infty$$

thus giving an actual measure of how rapidly $h(D)$ tends to infinity. Siegel's formula has made possible other developments, such as I. M. Vinogradow's startling achievement of 1937, when he proved (without any unproved hypothesis) that every large odd number is a sum of three odd primes.

2. Distribution of Primes; Asymptotic Formulas.—In 1837 Dirichlet proved that there are infinitely many primes in any arithmetic progression $my + n (y = 0, 1, 2, \cdots)$, where m and n are any given coprime integers, m positive. In his article, analytic methods using fairly deep results from the theory of functions were first introduced into the theory of numbers. A number of special cases, notably $my \pm 1$, have been proved by strictly elementary methods. It is not known whether quadratic expressions such as $x^2 + 1$ represent infinitely many primes. However,

if $f = au^2 + buv + cv^2$ is primitive and not negative-definite, if $(m, n) = 1$ and the congruence $f \equiv n \bmod m$ is solvable, then f represents infinitely many primes of the form $my + n$.

Consider two functions $f(x)$ and $g(x)$ which tend to infinity with x. Examples are $\pi(x)$ = the number of primes up to x; and the function $\frac{x}{\log_e x}$. If the ratio $\frac{f(x)}{g(x)}$ tends to 1 as a limit when x tends to infinity, we say that $f(x)$ is asymptotic to $g(x)$, abbreviated $f(x) \sim g(x)$. The difference $f(x) - g(x)$, or the error in approximating $f(x)$ by $g(x)$, may then still become large with x, but will be of smaller order of size than $g(x)$. It is frequently important to estimate the magnitude of this error. The notation used for this purpose is illustrated by the equation $(x + 1)^3 = x^3 + O(x^2)$; which means that there exists a positive constant c such that, for all sufficiently large values of x, $|(x + 1)^3 - x^3| < cx^2$; here, $|3x^2 + 3x + 1| < 7x^2$ if $x > 1$. Generally, if F is a positive function of x, $O(F)$ denotes a function of x which, for all sufficiently large x, does not exceed cF in absolute value, where c is a positive constant. Examples: $\sin x = O(1)$, $(\log x)^{10} = O(x)$.

P. L. Chebichev gave asymptotic formulas for

$$\sum \frac{1}{p} \text{ and } \Pi\left(1-\frac{1}{p}\right)$$

where p ranges over the primes less than x; and proved Bertrand's postulate on the existence of a prime between x and $2x (x \geqq 2)$. Asymptotic formulas for $\pi(x)$ had been suggested by Legendre and Gauss. The simplest formula is $\pi(x) \sim x/\log x$, proved independently by J. Hadamard and C. de la Vallée Poussin in 1896. A closer approximation is given by

$$\int_2^x \frac{dx}{\log_e x}$$

the error being proved by J. E. Littlewood (1924) as $O(xe^{-t})$, with $t^2 = k \log x \log \log x$ (k a positive constant); and improved by N. Tchudakov (1947) to $t = (\log x)^\delta$, $\delta = 0{\cdot}6 - \epsilon$. The Riemann zeta function hypothesis discussed above is equivalent to the statement that the error is $O(x^{\frac{1}{2}} \log x)$.

We state a few of the simplest examples of asymptotic formulas for number-theoretic functions. For Euler's function (see *Residue classes*, above)

$$\phi(n), \phi(1) + \phi(2) + \cdots + \phi(n) = \frac{3n^2}{\pi^2} + O(n \log n)$$

The number of pairs of integers u, v satisfying $u^2 + v^2 \leqq x$ is $\pi x + O(x^{\frac{1}{3}})$. This exponent $\frac{1}{3}$ can be lowered, though it must exceed $\frac{1}{4}$, and exceedingly delicate analysis has gone into proving that we can take the exponent as low as $\frac{13}{40}$. If x is a prime, the least primitive root of x is $O(x^{\frac{1}{4}+\epsilon})$, where ϵ is any desired positive number (see *Primitive Roots*, above). If $r(x)$ denotes the number of representations of the integer x as a sum of three squares, and x is not of the form $4n$ or $8n + 7$, then $\log r(x) \sim \log \sqrt{x}$ (Siegel, 1935).

A later development of interest is the elementary proof of the fact that $\pi(x) \sim x/\log x$, by Atle Selberg (1949). His method also was applied to prove Dirichlet's theorem on the infinitude of primes in an arithmetic progression. In the same year, an elementary proof of Dirichlet's theorem based on algebraic numbers was published by H. Zassenhaus.

An interesting, as yet unproved, conjecture states there exist infinitely many pairs of primes differing by two (*e.g.*, 3, 5; 197, 199); such pairs are called twin primes. However, if their number is infinite, they are distributed much more sparsely than the primes themselves, since, as was shown by Viggo Brun in 1921, the sum of the reciprocals of the twin primes is finite, while the sum of the reciprocals of all primes is infinite.

IV. ADDITIVE THEORY OF NUMBERS

A typical problem of the additive theory of numbers may be described as follows. Consider a set S of integers $a_1, a_2, \cdots$; *e.g.*, S might contain the primes, or the cubes of primes, or the squares. Let $r(n)$ denote the number of representations of a positive integer n as a sum of s elements a_i of S. The problem is to find out what we can about $r(n)$; *e.g.*, whether $r(n)$ is always positive; or positive for all sufficiently large n; or to obtain an exact or approximate formula for $r(n)$.

1. Partitions. In particular, if $S = (1, 2, 3, \cdots)$, consists of all positive integers, the number s of summands is unrestricted, repetitions are allowed, and order is irrelevant, we have the problem of unrestricted partitions; *i.e.*, one of expressing a positive integer n as a sum of positive integers. Thus 4 has five partitions: 4, $3 + 1$, $2 + 2$, $2 + 1 + 1$, $1 + 1 + 1 + 1$.

A number of interesting facts can be proved by elementary methods, such as representing a partition by an array of dots, and collecting these dots in different orders. Thus: the number of partitions of n into m parts is equal to the number of partitions of n into parts the largest of which is m. If $p(n)$ denotes the number of partitions of n, then

$$1 + \sum p(n)x^n = \frac{1}{\{(1-x)(1-x^2)(1-x^3)\cdots\}}$$

called a generating function for $p(n)$. Generating functions are constructible for partitions variously restricted; *e.g.*, into odd parts, unequal parts, parts of the form $5n \pm 1$, etc. By transformation of generating functions results such as the following appear (those stated being first given by Euler): the number of partitions of n into unequal parts is equal to the number of its partitions into odd parts; if $E(n)$ is the number of partitions of n into an even number of unequal parts, and $U(n)$ the number into an odd number of unequal parts, then $E(n) - U(n) = 0$ unless n is of the form $\frac{1}{2}k(3k \pm 1)$, when $E(n) - U(n) = (-1)^k$. Again, the number of partitions of n into parts which differ by at least 2 is equal to the number of partitions into parts of the form $5m \pm 1$.

Among the most important later developments, we should mention an asymptotic formula for $p(n)$, developed by Hardy and S. Ramanujan (1917); and an exact expression for $p(n)$ by an infinite series, presented by H. Rademacher (1937).

2. The Waring Problem, and Related Problems.—Interest in forms capable of representing all positive integers goes back to Diophantus, of the 3rd century, who (according to Bachet de Méziriac, 1621) assumed that every positive integer is a sum of four squares. Fermat (1636) stated that: "every number is either triangular or the sum of two or three triangular numbers; every number is either a square or a sum of two, three or four squares; either pentagonal, or the sum of two, three, four, or five pentagonal numbers; and so on ad infinitum whether it is a question of hexagonal, heptagonal, or any polygonal numbers." (If billiard balls are stacked into a triangle, the number of balls will be $1 + 2 + \cdots + x = \frac{1}{2}x(x + 1)$, called a triangular number. Generally, a polygonal number of order m is given by $x + \frac{1}{2}(m - 2)(x^2 - x)$, where $x = 0, 1, 2, \cdots$; the squares are obtained when $m = 4$.) Fermat's theorem is that every positive integer is a sum of m polygonal numbers of order m.

This theorem was proved for squares by Lagrange (1772), for triangular numbers by Legendre (1798), for the remaining cases by A. L. Cauchy (1813–15).

In 1770 E. Waring stated an extension of the four square theorem in the direction of higher powers: every positive integer is a sum of at most 9 (positive, integral) cubes, also a sum of at most 19 fourth powers, at most 37 fifth powers, and in general of a limited number (whose least value we will denote by $g(k)$) of kth powers. That at least 9 cubes are required follows from the fact that 23 and 239 cannot be represented by sums of fewer cubes. The son of the great Euler noticed an integer which requires at least $2^k - 2 + [(\frac{3}{2})^k]$ kth powers. Here the symbol $[t]$ denotes the greatest integer in t.

The function $G(k)$ giving the least number of kth powers required to represent all but a finite number of positive integers is of even greater interest. Evidently $G(k) \leqq g(k)$. By Lagrange's result, $G(2) = g(2) = 4$.

Starting about the middle of the 19th century, the finiteness

of $g(k)$ was gradually proved by means of elementary but complicated methods, first for $k = 4$, then for $k = 3, 5, 6, 7, 8, 10, 12$ and 14; and finite upper bounds to $g(k)$ (which, except for $k = 3$, were not best possible) were obtained. The problem of finding anything general about $g(k)$ or $G(k)$ seemed hopeless until D. Hilbert, in a famous paper of 1909, proved the fact that $g(k)$ is finite for every k. His proof is not exactly elementary, since it is based on the transformation of a 5-fold integral (in his first presentation, a 25-fold integral). The transcendental character of his proof was eliminated by various writers, but it is still a pure existence proof and gives no method of estimating $g(k)$.

The really great invention which opened up the whole subject was the work (1917) of Hardy and Littlewood, and Ramanujan. A very important step depended on H. Weyl's previous investigation of exponential sums. By use of A. L. Cauchy's integral formula, an expression can be constructed for the coefficient c_n in the expansion of

$$(1 + x^{1^k} + x^{2^k} + \cdots)^s = \sum_{n=0}^{\infty} c_n x^n$$

Briefly, the main contribution of Hardy and Littlewood to Waring's problem and similar problems was that they invented a way to prove that if $s \geqq (k-2)2^{k-1} + 5$, at most a finite number of coefficients in the above expansion vanish, and hence $G(k) \leqq (k-2)2^{k-1} + 5$, and that they found an asymptotic expression for c_n, that is the number of ways n can be expressed as a sum of s kth powers. Later they found smaller bounds for $G(k)$.

Although Hardy and Littlewood proved that every sufficiently large integer is a sum of 19 fourth powers, 41 fifth powers, $\cdots$, 425 eighth powers, etc., they did not compute actual limits beyond which these facts would hold true. Hence their work gave no immediate information about the size of Waring's constant $g(k)$. In the hope of being able to prove Waring's original statement with the best possible values $g(k)$, L. E. Dickson urged certain of his students about 1930 to find lower limits to the constants in the Hardy-Littlewood analysis. R. D. James succeeded in this, and proved $g(6) \leqq 183$, $g(7) \leqq 322$, $g(8) \leqq 595$, in 1934; but the limits given by the Hardy-Littlewood method soon became impracticable.

The next and most important step came from the great Russian mathematician, I. M. Vinogradow. Vinogradow's earlier researches on the Waring problem had appeared in 1924; his methods were similar to those of Hardy and Littlewood, but led more rapidly to certain results. In his later work he made very important improvements, and found results which for large k were much better than those previously obtained. In particular, he ultimately proved $G(k) \leqq k(3 \log k + 10)$.

With the appearance of Vinogradow's new results, L. E. Dickson in the U.S. and S. S. Pillai in India investigated the possibility of proving the Waring conjecture in the original sense with best possible values $g(k)$, and both arrived independently in 1936 at an "almost complete" solution. Let $q = [(\frac{3}{2})^k]$. They proved that $g(k) = 2^k + q - 2$ if $k \geqq 7$, and

$$(\tfrac{3}{2})^k - q \leqq 1 - (\tfrac{1}{2})^k (q+3) \tag{1}$$

This condition is satisfied if $k \leqq 400$, and possibly for every k. When (1) does not hold, the formula for $g(k)$ is different, but was determined except for those values k (if any) satisfying

$$(\tfrac{3}{2})^k - q = 1 - (\tfrac{1}{2})^k (q+2) \tag{2}$$

The exceptional case (2) was finally solved in 1944 by I. Niven. Further, (although his proof may require minor corrections) Pillai proved that $g(6) = 73$ in 1940. Accordingly, Waring's problem was completed (1944) as regards $g(k)$, except when $k = 4$ and 5.

The best results for these cases were those of Dickson (1933) that $19 \leqq g(4) \leqq 35$, $37 \leqq g(5) \leqq 54$; and Davenport (1942 and 1939), that $G(5) \leqq 23$ and $G(4) = 16$. The latter is a best possible result, since the infinitely many numbers $16^k \cdot 31$ require 16 fourth powers. It was, up to 1944, the only best possible result known for $G(k)$, $k \geqq 3$.

In 1909 (except for an omission supplied by A. J. Kempner in 1912) A. Wieferich proved that $g(3) = 9$. In the same year Edmund Landau showed that $G(3) \leqq 8$. In 1944 Y. V. Linnik gave a proof (a lacuna being later filled) that $G(3) \leqq 7$. Dickson proved in 1939 that every number except 23 and 239 is a sum of eight cubes. Numerous generalizations of the Waring problem have been investigated, such as sums of kth powers of primes, integral valued polynomials, etc.

3. The Goldbach Problem. In an exchange of letters (1742) between Euler and C. Goldbach, it was conjectured that every integer is a sum of three primes, and every even integer a sum of two primes. Not considering 1 as prime, and omitting the even prime 2, we may formulate these conjectures for odd integers $\geqq 9$ and even integers $\geqq 6$.

No essential progress was made in solving this problem until the result (1923) of Hardy and Littlewood based on the G.R.H. (see *Gauss's Class-number Conjecture*, above). In 1930, L. Schnirelmann proved that every positive integer can be represented by a sum of at most 800,000 primes. This number was lowered to 2,208 by N. P. Romanoff in 1935; to 71 by Heilbronn, Landau, and H. F. Scherk in 1936; to 67 by G. Ricci in 1937. Supplementing the analytic methods of Hardy and Littlewood by powerful new methods of his own, Vinogradow proved that every sufficiently large odd number is a sum of three odd primes, in 1937. In the first award of the Stalin prizes in 1941, Vinogradow received a first prize of 100,000 rubles for his work on the Goldbach problem.

V. DIOPHANTINE APPROXIMATION

1. Geometry of Numbers.—A lattice (in the plane) is the configuration formed by two systems of equidistant parallel lines. The points of intersection form a point lattice. A lattice L can be defined analytically by two linear forms with real coefficients and integer variables: if x and y take all integral values, the points with rectangular co-ordinates $(\alpha x + \beta y, \gamma x + \delta y)$, where $\alpha, \beta, \gamma, \delta$ are given real numbers, form a point lattice. The four points $O = (0, 0)$, $P = (\alpha, \gamma)$, $Q = (\beta, \delta)$, $R = (\alpha + \beta, \gamma + \delta)$ are the vertexes of a fundamental parallelogram, with area $\Delta = \alpha\delta - \beta\gamma$ (which we assume not zero). In particular, if $\alpha = \delta = 1$, $\beta = \gamma = 0$, the lattice consists of all points (x, y) with integral co-ordinates. Any linear transformation $x = ax' + by'$, $y = cx' + dy'$, where a, b, c, d are integers and $ad - bc = +1$, produces a different system of parallelograms based on the same point lattice. The lattices so derived are said to be equivalent. The area Δ of a fundamental parallelogram is the same for equivalent lattices.

Consider a parallelogram with centre at O, and with two lattice points. P_1 and Q_1 of L as midpoints of adjacent sides. Let the area of the parallelogram be $4k$. If $k = \Delta$ (which is least possible), there are at least 8 points of L on the boundary, but none (except O) in the interior of the parallelogram. This fact is a special case of a famous theorem of Minkowski, which asserts that any simple, closed, convex region R symmetrical about O, and of area greater than 4Δ, contains within it points of L other than O. One may think of R as the interior of a parallelogram or of an ellipse. This theorem can be extended to n dimensions.

Other important theorems of Minkowski (some of the proofs of which use the above theorem on convex bodies) concern sets of n linear forms $\xi_i = \alpha_{i1}x_1 + \cdots + \alpha_{in}x_n$ $(i = 1, \cdots, n)$, with real coefficients α_{ij} and n integral variables $x_1, \cdots, x_n$. Supposing, for simplicity that $n = 2$, we have $\xi = \alpha x + \beta y$, $\eta = \gamma x + \delta y$. Let D denote the absolute value of the determinant $\alpha\delta - \beta\gamma$, and assume $D \neq 0$. One theorem asserts that there exist integers x and y not both zero, such that $|\xi\eta| \leqq \frac{D}{\sqrt{5}}$. A second theorem states that if b and c are positive numbers such that $bc \geqq D$ (*e.g.*, if $b = c = \sqrt{D}$), then there exist integers x and y not both zero such that $|\xi| \leqq b$ and $|\eta| \leqq c$. Both these theorems extend to n dimensions. A third theorem asserts that if ρ and σ are given real numbers, we can find integers x and y such that

$$|(\alpha x + \beta y - \rho)(\gamma x + \delta y - \sigma)| \leqq \tfrac{1}{4}D$$

The obvious extension to n linear forms would have $\frac{D}{2^n}$ on the

right. The case $n = 3$ was proved by R. Remak in 1923, but the cases $n \geqq 4$ had up to 1945 defied attempts at proof. The case $n = 4$ was proved by F. J. Dyson in 1948. After 1938, powerful methods of investigating certain nonconvex regions were developed by L. J. Mordell, H. Davenport and K. Mahler.

2. Diophantine Approximation.—The literature on the approximation of irrational numbers by rational fractions is very extensive. We saw, by continued fractions, that if θ is any irrational number, there are infinitely many rational fractions

$$\frac{p}{q} \text{ such that } \left|\theta - \frac{p}{q}\right| < \frac{1}{q^2}$$

A different proof (which is based on Dirichlet's principle that if $n+1$ objects are in n boxes, then at least one box contains two or more objects) is worth giving, because it extends easily to n-dimensional problems. Let (x) denote $x-[x]$; *i.e.*, the fractional part of x. The $Q+1$ numbers (0), (θ), (2θ), $\cdots$, $(Q\theta)$ define $Q+1$ points distributed among the Q intervals

$$0 \text{ to } \frac{1}{Q}, \frac{1}{Q} \text{ to } \frac{2}{Q}, \cdots, \frac{(Q-1)}{Q} \text{ to } 1$$

At least one interval must contain two numbers, say $(q_1\theta) = q_1\theta - p_1$, $(q_2\theta) = q_2\theta - p_2$, where p_1, p_2, q_1, q_2 are integers, and $0 \leqq q_1 < q_2 \leqq Q$. Hence $p = p_2 - p_1$ and $q = q_2 - q_1$ satisfy

$$|q\theta - p| < \frac{1}{Q}, \left|\theta - \frac{p}{q}\right| < \frac{1}{qQ} \leqq \frac{1}{q^2}$$

If θ is irrational, there will be a larger Q_1 such that

$$|q\theta - p| > \frac{1}{Q_1}$$

new approximations can be determined by means of Q_1. An extension of this argument proves the result of Dirichlet: If $\theta_1, \theta_2, \cdots, \theta_k$ are any real numbers, then one can find integers $p_1, \cdots, p_k$, and q such that

$$\left|\frac{p_i}{q} - \theta_i\right| < \frac{1}{q^{1+1/k}}, \ (i = 1, \cdots, k)$$

if at least one θ_i is irrational there are infinitely many solutions p_i and q.

In 1884 L. Kronecker proved that if θ is any irrational number there are integers n such that $(n\theta)$ is as near as we please to any number in the interval 0 to 1; briefly, $(n\theta)$ is dense on the interval $(0, 1)$. Moreover, as proved about 1912, this distribution is uniform over the interval $(0, 1)$; *i.e.*, if I denotes a subinterval of $(0, 1)$ of length I_1, and if n_I of the points (θ), (2θ), $\cdots$, $(n\theta)$ fall in I, then $\frac{n_I}{n} \to I_1$, as $n \to \infty$. In *Mathematische Annalen*, 77 (1916), Weyl proved that a necessary and sufficient condition for uniform distribution of the numbers $(f(n))$, $n=1$, 2, 3, $\cdots$, is that $\frac{1}{n}\sum_{k=1}^{n} e^{2\pi i h f(k)} \to 0$ as $n \to \infty$ for every integer h.

Transcendental Numbers.—Any real number which is not algebraic (*see* below) is called transcendental. Interest in transcendental numbers perhaps first arose in connection with the classical problem of squaring the circle, one which could be performed by Euclidean constructions if and only if the number π were expressible by means of square roots and rational operations. The impossibility of this construction was demonstrated when F. Lindemann proved the transcendence of π in 1882.

Liouville proved a theorem which shows how to obtain as many transcendental numbers as we please (1851). It states that if ξ is a real algebraic number of degree η and K is any constant, then there exist at most a finite number of rational fractions

$$\frac{p}{q} \text{ such that } \left|\frac{p}{q} - \xi\right| < \frac{K}{q^{n+1}}$$

Hence a number with a sufficiently rapid sequence of rational approximations is transcendental (*e.g.*, this is true of .1010010-0010$\cdots$).

Among the numbers known to be transcendental we may mention e, π, $\log_e 2$, $2^{\sqrt{2}}$, e^{π}. In 1900, Hilbert proposed the problem of proving that if α and β are algebraic numbers, α not 0 or 1, and β is irrational, then α^β is transcendental. This was proved in 1934 by Alexis O. Gelfond and T. Schneider, independently.

VI. GENERALIZATIONS OF ARITHMETIC

1. Algebraic Numbers.—Gauss was the first to extend the notions of arithmetic (integrality, divisibility, primality, etc.) to systems other than the ordinary integers. He defined a complex number $a = a_0 + a_1 i$ (where a_0, a_1 are rational numbers and $i^2 = -1$) to be a complex integer if a_0 and a_1 are ordinary integers. Ordinary integers will hereafter be called rational integers. Divisibility is defined as usual: $b|a$ if $a = bc$ in complex integers. The number $a_0 - a_1 i$, called the conjugate of a, may be designated by a'. The product aa' is the rational integer $a_0^2 + a_1^2$, and is called the norm of a. If $a = bc$, then $a' = b'c'$, $aa' = (bb')(cc')$, so that the norm of b is a factor (in the ordinary sense) of the norm of a. The only complex integers which divide all complex integers are those of norm 1, the units ± 1 and $\pm i$. If $b|a$ then the associates ub of b, where u is any unit, are also factors of a. If the complex integer p (not a unit) has no factors other than its associates and units, p is called a prime. It turns out that $p = p_0 + p_1 i$ is a complex prime if the norm of p is a rational prime of the form $4n + 1$, or if $p = \pm(1 \pm i)$, or if p is the associate of an ordinary prime of the form $4n + 3$. One proves that $p \mid ab$ only if $p \mid a$ or $p \mid b$, and deduces the fundamental theorem of arithmetic in the system of complex integers. Virtually all the theorems of ordinary theory of numbers have analogues among complex integers.

E. E. Kummer, in studying Fermat's equation $x^n + y^n = z^n$ (*see* FERMAT'S LAST THEOREM), developed the theory of integral elements in the fields generated by nth roots of unity (Gauss's case is $n = 4$), and found (about 1847) that the fundamental theorem of arithmetic does not always hold true in such systems.

To illustrate this, consider the system of numbers $a = a_0 + a_1\theta$, where $\theta^2 = -5$ and the a_i are rational numbers; a is called integral if the a_i are rational integers. The conjugate a' is now $a_0 - a_1\theta$ and the norm of a is $aa' = a_0^2 + 5a_1^2$. As before, if $b|a$, then the norm of b divides the norm of a. Hence the units (of norm 1) are ± 1. The number $1 + \theta$ (of norm 6) must be a prime, because neither 2 nor 3 are norms. This prime $1 + \theta$ is a divisor of $(1 + \theta)(6 + 5\theta) = -19 + 11\theta = (-1 + 3\theta)(4 + \theta)$. But $1 + \theta$ is not a divisor of $4 + \theta$, since the norm 6 does not divide the norm 21. Hence the fundamental theorem of arithmetic (with many of its consequences) does not hold.

If θ is a real or complex solution of an algebraic equation of the type $a_0x^n + a_1x^{n-1} + \cdots + a_n = 0$, where the coefficients a_i are rational numbers, θ is called an algebraic number. It is called an algebraic integer if it satisfies such an equation with $a_0 = 1$, and $a_1, \cdots, a_n$ integers. Examples are i and $\sqrt[3]{6}$. One frequently considers the algebraic integers in a given algebraic field, which consists of all numbers of the form $b_0 + b_1\theta + b_2\theta^2 + \cdots + b_r\theta^r$ with rational coefficients b_i. The sum, difference, and product of two algebraic integers in a field are easily seen to be algebraic integers in the same field.

2. Ideals.—Suppose that S is the system of all algebraic integers, denoted by $a, b, \cdots, s, t$ in a given algebraic field. Divisibility, units, associates, etc. are defined much as in the preceding two examples. Factorization into primes may not be unique. However, by adjoining to the system S a set of ideals, presently to be defined, the fundamental theorem of arithmetic can be made to hold.

If $a = bc$, then clearly the set of all multiples sa of a (where s ranges over all the integral elements of S) is included in the set of all multiples sb of b. Thus the notion of divisibility of integers can be replaced by the notion of inclusion of one set in another. The set of all multiples sa of a given number a will be called an ideal, more specifically, a principal ideal. More generally, an ideal is a set of numbers in an algebraic field, such that if u and v are any numbers in the set then $su + tv$ are in the set, where s and t range over all the integers of the field. In the case of rational in-

tegers, if u and v are any rational integers not both zero, then the set of numbers $su + tv$ is the same as the set of numbers md, where d is the g.c.d. of u and v; hence every ideal is then principal. The same is true in Gauss's case of numbers $a_0 + a_1i$. But the field generated from $\theta^2 = -5$ contains nonprincipal ideals.

The product of two ideals is the ideal obtained by multiplying each element of one by each element of the other, and then constructing all combinations $su + tv$ (s and t integral, u and v in the ideal). The principal ideal consisting of all multiples sa of a will be denoted by (a); the ideal consisting of all combinations $su + tv$ by (u, v). It can be shown that every ideal in an algebraic field can be expressed in this way by one or two terms. The ideal (1) plays the role of the number 1; *i.e.*, for any ideal α, $(1)\,\alpha = \alpha$. An ideal whose elements are algebraic integers is called integral. A prime ideal is an integral ideal with no divisors except itself and (1).

The fundamental theorem of arithmetic can be shown to hold in an algebraic field, if each algebraic integer a is replaced by its principal ideal (a), and the system is enlarged to encompass all the integral ideals of the field: every ideal which is not a prime can be expressed as a product of prime ideals in only one way.

This may be illustrated in the above example with $\theta^2 = -5$ as follows. Let $\alpha = (1 + \theta, -1 + 3\theta)$, $\beta = (1 + \theta, 4 + \theta)$, $\gamma = (6 + 5\theta, -1 + 3\theta)$, $\delta = (6 + 5\theta, 4 + \theta)$. The ideals $\alpha, \beta, \gamma, \delta$ are easily shown to be prime ideals (with respective norms 2, 3, 23, and 7), and the factorization of $(-19 + 11\theta)$ into prime ideals is simply $\alpha\beta\gamma\delta$. The factorizations previously given were $\alpha\beta\cdot\gamma\delta = (-19 + 11\theta) = \alpha\gamma\cdot\beta\delta$, and it is not surprising that $\alpha\beta|\alpha\gamma\cdot\beta\delta$ without dividing $\alpha\gamma$ or $\beta\delta$.

3. Algebras, and Their Arithmetics. Other generalizations of number are found in the extensive theory of linear algebras, which we will illustrate only very briefly. A simple example is the algebra of quaternions (*see* QUATERNIONS). These are symbols of the form $a = a_0\cdot 1 + a_1i_1 + a_2i_2 + a_3i_3$, where we will suppose the a_i to be rational numbers, and the basal elements $1, i_1, i_2, i_3$ satisfy the multiplication table $1\cdot b = b\cdot 1 = b, i_1^2 = i_2^2 = i_3^2 = -1, i_1i_2 = i_3 = -i_2i_1, i_2i_3 = i_1 = -i_3i_2, i_3i_1 = i_2 = -i_1i_3$. Algebraic operations are performed in the usual way, except that multiplication is in general not commutative (*e.g.*, $i_1i_2 \neq i_2i_1$), and the order of multiplication must be preserved. The resulting algebra has many applications, physical and geometrical. The question here is, what shall be meant by an integral quaternion?

In 1886, R. Lipschitz defined a to be integral if the co-ordinates a_i are rational integers, and was able to prove the following result resembling the fundamental theorem of arithmetic. Define a', the conjugate of a, to be $a_0 - a_1i_1 - a_2i_2 - a_3i_3$. The product aa' will be found to be $a_0^2 + a_1^2 + a_2^2 + a_3^2$, a rational integer called the norm of a, abbreviated $N(a)$. From $a = bc$ follows $a' = c'b'$, and hence $aa' = (bc)(c'b') = b(cc')b' = (bb')(cc')$, or $N(a) = N(b)N(c)$. The units are the eight quaternions $u = \pm 1, \pm i_1, \pm i_2, \pm i_3$ of norm 1. If b is a left divisor of a (*i.e.*, $a = bc$ in integral quaternions), then the right associates bu are also left divisors of a.

A prime quaternion is an integral quaternion a (not a unit) such that if $a = bc$ in integral quaternions, then b or c is a unit. It is easily proved that a quaternion is prime if and only if its norm is a rational prime number; *e.g.* $1 + i_1$ of norm 2, $2 + i_1 - 2i_2 + 2i_3$ of norm 13. Factorization into primes is in general not unique. For example, $3 = (1 + i_1 + i_2)\ (1 - i_1 - i_2) = (1 + i_1 + i_3)(1 - i_1 - i_3)$, yet the primes $1 + i_1 + i_2$ and $1 + i_1 + i_3$ are not right associates. However, suppose now that a is primitive, *i.e.* that a_0, a_1, a_2, a_3 are relative-prime, and that $N(a)$ is not divisible by 4. Factor $N(a) = p_1p_2\cdots p_r$ into rational primes, not necessarily distinct, but in a definite order. Lipschitz's result is this: there exist prime quaternions $t_1, t_2, \cdots, t_r$ of respective norms $p_1, p_2, \cdots, p_r$ such that $a = t_1t_2\cdots t_r$; this factorization into primes is unique, for the given order of $p_1, \cdots, p_r$, except that we can introduce unit factors in the trivial way illustrated by $t_1t_2t_3 = (t_1i_1)(-i_1t_2i_3)(-i_3t_3)$. This theorem yields a large number of arithmetical applications; *e.g.*, he proved thereby the formula for the number of representations of integers as a sum of 4 squares.

However, the definition of integral quaternion was somewhat arbitrary. A. Hurwitz was led by natural considerations to define a to be integral if the a_i are either all integers, or all halves of odd integers. For example, $\frac{1}{2}(1 + i_1 - i_2 + i_3)$ is integral, of norm 1. The resulting arithmetic is better behaved with respect to the prime 2 (it being unnecessary to restrict $N(a)$ to be not divisible by 4,—but still necessary to assume a primitive).

We owe, finally, to L. E. Dickson an adequate and unique characterization of a system of integral elements in any linear algebra (*Algebras and Their Arithmetics* [1923]). This includes Hurwitz's system and the theory of algebraic integers as special cases, and has formed the basis of much subsequent work.

The first half of the 20th century saw many extensions of the theory of numbers to various algebraic systems. Not all theorems extend easily, and some lead to rather surprising results. The prospects for original research were, by the 1960s, by no means exhausted.

NUMBER SEQUENCES are sets of numbers arranged in order so that there is a first, a second and so on. The sequence may be finite or infinite, according as the number of terms is limited or unlimited. The best-known infinite sequence comprises the natural numbers listed in order of size: 1, 2, 3, 4, 5, ... A number sequence is to be distinguished from a mere set or collection of numbers. In fact there are sets of numbers which, it can be proved, cannot be arranged as sequences. An illustration of this is the set of all positive real numbers, which can be conceived as the collection of the lengths of all possible straight line segments, measured against some arbitrary unit of length such as one inch.

A few cases of number sequences as they arise in various parts of mathematics are sketched below.

Simple Sequences.—Arithmetic progressions, harmonic progressions and geometric progressions are types of simple sequences. An arithmetic progression is a sequence in which the difference between any two successive terms is the same, say the constant difference d. If the first term is denoted a, then the arithmetic progression can be written in the form

$$a, a + d, a + 2d, a + 3d, \ldots$$

It can be established that the nth term of this sequence is given by $a + (n - 1)d$, and the sum of the first n terms by

$$\tfrac{1}{2}n[2a + (n - 1)d]$$

An arithmetic progression, then, is a sequence for which the first differences are constant. Now consider the sequence of squares of the natural numbers: 1, 4, 9, 16, 25, 36, . . . , n^2, ... Here the first differences are 3, 5, 7, 9, 11, . . . , and the second differences are constant: 2, 2, 2, 2, ... Whenever a number sequence has constant second differences, it must be formed by some second-degree algebraic expression; the simplest example, n^2, has just been cited.

A more complicated example is the sequence 2, 4, 12, 26, 46, . . . formed by the algebraic expression $3n^2 - 7n + 6$ by substituting successively $n = 1$, $n = 2$, $n = 3$ and so on. It also has constant second differences; in this case each equals 6. This law generalizes: if a sequence has constant kth differences, then the sequence must be formed by an algebraic expression of degree k. Thus if a sequence derives from a third-degree algebraic expression (*e.g.*, n^3) the third differences are constant.

An interesting result (P. G. L. Dirichlet) concerning arithmetic progressions of natural numbers is that if a and d have no common divisor, as for example in case $a = 7$ and $d = 10$, then the sequence contains infinitely many prime numbers. (The prime numbers are 2, 3, 5, 7, 11, 13, 17, . . . ; *see* ARITHMETIC: *Theory of Divisors*.)

A harmonic progression is a sequence of numbers with reciprocals that form an arithmetic progression; *e.g.*, $\frac{1}{3}, \frac{1}{5}, \frac{1}{7}, \frac{1}{9}, \frac{1}{11}, \ldots$. A geometric progression is a sequence such that the ratio of any two consecutive terms is the same number, say r. If the first term is denoted a, then a geometric progression can be written in the form

$$a, ar, ar^2, ar^3, ar^4, \ldots$$

The nth term is given by ar^{n-1} and the sum of the initial n terms of this sequence is obtained from

$$\frac{a(1 - r^n)}{1 - r}$$

If r falls between -1 and $+1$, the expression for the sum of n terms approaches $a/(1 - r)$ as n increases beyond all bounds. A familiar case of this occurs in any infinite repeating decimal. For example, the number .232323 . . . can be thought of as the sum of all terms of the sequence

$$\frac{23}{100}, \frac{23}{10{,}000}, \frac{23}{1{,}000{,}000}, \ldots$$

This is the infinite geometric progression with $a = \frac{23}{100}$, $r = \frac{1}{100}$, and with sum $\frac{23}{99}$.

Geometric progressions play a considerable role in the mathematics of finance, because a sum of money that is earning compound interest grows from one interest period to the next in the form of a geometric progression.

The Role of Sequences in Calculus.—Modern formulations of calculus lean heavily on limits of infinite sequences. An infinite sequence $a_1, a_2, a_3, \ldots$ is said to have limit b if $a_n - b$ becomes arbitrarily small as n increases; technically stated, the sequence has limit b if for any given positive number ϵ all but a finite number of terms of the sequence $a_1 - b, a_2 - b, a_3 - b, \ldots$ lie between ϵ and $-\epsilon$. The sequence $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \ldots$, for example, has limit 1. Not all sequences have limits, as in the case $2, \frac{1}{2}, 3, \frac{1}{3}, 4, \frac{1}{4}, 5, \frac{1}{5}, \ldots$. The integral concept in calculus can be defined as a limit of a sequence, and one of the central problems of the theory is to show that such sequences have limits (*see* LIMIT).

Definition of Irrational Numbers.—There are alternative ways of defining the system of real numbers, comprising the rational and irrational numbers (*see* NUMBER), to put the matter on a solid logical foundation. One standard way (G. F. L. P. Cantor) is to define irrational numbers as limits of appropriate sequences of rational numbers. A sequence of rational numbers $a_1, a_2, a_3, \ldots, a_n, \ldots$ to be used in defining a number must be a regular sequence, in the sense that to every positive number ϵ there corresponds an integer n such that $a_m - a_n$ lies between ϵ and $-\epsilon$ whenever m is greater than n. Two regular sequences $a_1, a_2, a_3, \ldots$ and $b_1, b_2, b_3, \ldots$ define the same number if the sequence $b_1 - a_1, b_2 - a_2, b_3 - a_3, \ldots$ has limit zero. For example $\sqrt{2}$ may be defined by the decimal sequence 1, 1.4, 1.41, 1.414, 1.4142, . . . , the successive terms of which can be determined by any of the customary methods for computing square roots. The number $\sqrt{2}$ may be defined by other sequences; for instance, by 2, 1.5, 1.42, 1.415, 1.4143, ... By applying the preceding theoretical test to these two sequences, it is found that $b_1 - a_1, b_2 - a_2, b_3 - a_3, \ldots$ is the sequence 1, .1, .01, .001, . . . with limit zero.

Algebraic operations such as addition and multiplication are readily defined for regular sequences, simply by addition and multiplication of corresponding terms, and it can be proved that these operations again yield regular sequences. It is found that, if this process is repeated and regular sequences of real numbers are examined, such sequences always have real numbers as limits; thus no further extension of the number system in this direction is necessary.

NUMENIUS (2nd century A.D.), Greek philosopher, important as a forerunner of the Neoplatonism of Plotinus, was a native of Apamea in Syria. Though generally classed as a Neopythagorean, he is more accurately described as a Platonist. His hierarchy of three gods—the first, identical with Plato's "idea of the good," existing in self-contained transcendence; the second, the demiurge of Plato's *Timaeus*, which forms and rules the universe; and the third, the universe itself—seems to represent an attempt to get a systematic theology out of Plato's dialogues with the help of ideas borrowed from Aristotle and looks at first sight very like the hierarchy of being in Plotinus. But his first god is an Aristotelian "intellect," not the Plotinian "One"; and his second is much closer to Plotinus' higher soul than to his intellect. The works of Numenius, however, were much studied in the school of Plotinus.

NUMERALS AND NUMERAL SYSTEMS. Just as the first attempts at writing came long after the development of speech, so the first efforts at the graphical representation of numbers came long after people had learned to count. Probably the earliest way of keeping record of a count was by some tally system involving physical objects such as pebbles or sticks. Judging by the habits of primitive tribes of the present as well as by the oldest trace remaining of written or sculptured records, the earliest numerals were simple notches in a stick, scratches on a stone, marks on a piece of pottery or the like. Having no fixed units of measure, no coins, no commerce beyond the rudest barter, no system of taxation and no needs beyond those to sustain life, people had no necessity for written numerals until about the beginning of what are called historical times. Vocal sounds were probably used to designate the number of objects in a small group long before there were separate symbols for the small numbers and it seems likely that the sounds differed according to the kind of object being counted. The abstract notion of two, signified orally by a sound independent of any particular objects, probably appeared very late.

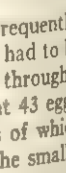
Number Bases.—When it became necessary frequently to count to numbers larger than 10 or so, the numeration had to be systematized and simplified; this was commonly done through use of a group unit or base, just as we might today count 43 eggs as three dozen and seven. In fact, the earliest numerals of which there is definite record were simple straight marks for the small numbers, with some special form for 10. These symbols appear in Egypt as early as the first dynasty (*c.* 3400 B.C.), and in Mesopotamia as early as *c.* 3000 B.C. These dates long precede the first known inscriptions containing numerals in India (*c.* 300 B.C.), in China (3rd century B.C.) and in Crete (*c.* 1200 B.C.). Some ancient symbols for 1 and 10 are as follows:

EGYPTIAN HIEROGLYPHIC, *c.* 3400 B.C. . . . .

EGYPTIAN HIERATIC, *c.* 3400 B.C. . . . .

CRETAN INSCRIPTIONS, *c.* 1200 B.C. . . . .

SUMERIAN AND LATER, *c.* 3000 B.C. . . . .



This special position occupied by 10 stems from the number of human fingers, of course, and is still evident in modern usage, not only in the logical structure of the decimal system but in the English names for the numbers. Thus eleven comes from Anglo-

Saxon *endleonfan*, literally meaning "(ten and) one left (over)," and twelve from *twe-lif*, meaning "two left"; the endings -teen and -ty both refer to 10, of course, and hundred comes originally from a pre-Greek term meaning "ten times (ten)."

It should not be inferred, however, that 10 is either the only possible base or the only one actually used. The pair system, in which the counting goes "one, two, two and one, two twos, two and two and one," etc., is found among the ethnologically oldest tribes of Australia, in many Papuan languages of Torres strait and the adjacent coast of New Guinea, among some African pygmies and in various South American tribes. Other tribes of Tierra del Fuego and the South American continent use number systems with bases three and four. The quinary scale, or number systems with base five, is very old, but in pure form seems to be used at present only in Saraveca, a South American Arawakan language; elsewhere it is combined with the decimal or the vigesimal system, where the base is 20. Similarly, the pure base six scale seems to occur only sparsely in northwest Africa, and is otherwise combined with the duodecimal, or base 12, system.

In the course of history the decimal system finally overshadowed all others, and it is now found in all nations of high culture on the entire globe, except those of Mexico and Central America, where the number 20 was used in astronomy and thus became firmly entrenched. Nevertheless, there are still many vestiges of other systems in our own culture, chiefly in commercial and domestic units, where change always meets the resistance of tradition. Thus there occurs 12 as the number of inches in a foot, pence in a shilling, months in a year, and twice 12 hours in a day; and both dozen and gross measure by twelves. In English the base 20 occurs chiefly in the word score ("Four score and seven years ago . . .") but other traces are found in pre-English Celtic, Gaelic, Danish and Welsh. The base 60 still occurs in measurement of time and angles.

NUMERAL SYSTEMS

It appears that the primitive numerals were |, ||, |||, and so on, as found in Egypt and the Grecian lands, or −, =, ≡, and so on, as found in early records in the far east, each going as far as the simple needs of people required. As life became more complicated, the need for group numbers became apparent, and it was only a small step from the simple system with names only for one and 10 to the further naming of other special numbers. Sometimes this happened in a very unsystematic fashion; very recently, for example, the Yukaghirs of Siberia counted, "one, two, three,

TABLE I.—*Comparison of Selected Systems of Numerals*

EUROPEAN	1	2	3	4	5	6	7	8	9	0

SIAMESE	๑	๒	๓	๔	๕	๖	๗	๘	๙	๐

three and one, five, two threes, two threes and one, two fours, ten with one missing, ten." Usually, however, a more regular system resulted, and most of these systems can be classified, at least roughly, according to the logical principles underlying them.

Simple Grouping Systems.—In its pure form a simple grouping system is an assignment of special names to the small numbers, the base b, and its power b^2, b^3, and so on, up to a power b^k large enough to represent all numbers actually required in use. The intermediate numbers are then formed by addition, each symbol being repeated the required number of times, just as 23 is written XXIII in Roman numerals.

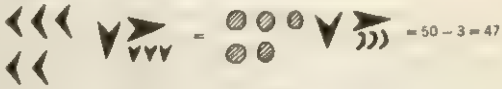
The earliest example of this kind of system is the scheme encountered in hieroglyphs which the Egyptians used for writing on stone. (Two later Egyptian systems, the hieratic and demotic, which were used for writing on clay or papyrus, will be considered below; they are not simple grouping systems.) The hieroglyphic symbols were:

Thus, since the Egyptians customarily wrote from right to left, they would have used for $243{,}688 = 2(10^5) + 4(10^4) + 3(10^3) + 6(10^2) + 8(10) + 8$ the symbol

Numbers of this size actually occur in extant records concerning royal estates and may have been commonplace in the logistics and engineering of the great pyramids.

Cuneiform Numerals.—Around Babylon, clay was abundant, and the people impressed their symbols in the damp clay tablets and then baked the tablets in the sun or in a kiln, thus forming documents which were practically as permanent as stone. Since the pressure of the stylus gave a wedge-shaped symbol, the writings are known as cuneiform (Lat. *cuneus*, a wedge, and *forma*, a shape) inscriptions. The symbols could be made either with the pointed or the circular end of the stylus, as follows:

For numbers up to 60 these symbols were used in the same way as the hieroglyphs, except that a subtractive symbol was also used:



The cuneiform and the curvilinear numerals occur together in some documents from about 3000 B.C. There seem to have been some conventions regarding their use; the cuneiform type was always used for the number of the year or the age of an animal, while wages already paid were written in curvilinear and wages due in cuneiform. For numbers larger than 60 the Babylonians used a mixed system, described below.

Greek Numerals.—The Greeks had two important systems of numerals, besides the primitive plan of repeating single strokes, as in ||| ||| for six, and one of these was again a simple grouping system. Their predecessors in culture—the Babylonians, Egyptians and Phoenicians—had generally repeated the units up to nine, with a special symbol for 10, and so on. The early Greeks also repeated the units to 9, and probably had various symbols for 10. In Crete, where the early civilization was so much influenced by those of Phoenicia and Egypt, the symbol for 10 was —, a circle was used for 100 and a rhombus for 1,000. Cyprus also used the horizontal bar for 10, but the precise forms are of less importance than the fact that the grouping by tens, with special symbols for certain powers of 10, was characteristic of the early systems of the near east.

The Greeks, entering the field much later, and influenced in their alphabet by the Phoenicians, based their first elaborate system chiefly on the initial letters of the numeral names. This was a natural thing for all early civilizations, since the custom of writing out the names for large numbers was at first quite general, and the use of an initial by way of abbreviation of a word is universal. These initial numerals, in modern characters, were

Π OR Γ, PI, FOR ΠΕΝΤΕ (PENTE), 5;
Δ, DELTA, FOR ΔΕΚΑ (DEKA), 10; OFTEN WRITTEN LIKE O;
H, AN OLD ATTIC BREATHING, LIKE OUR h, LATER REPRESENTED BY A SPECIAL SYMBOL LIKE Ͱ, FOR ΗΕΚΑΤΟΝ (HEKATON), 100,
X, CHI, FOR ΧΙΛΙΟΙ (CHILIOI), 1,000;
M, MU, FOR ΜΥΡΙΟΙ (MYRIOI, MURIOI), 10,000

These numerals were frequently combined with the symbol for 5; thus

ΓΔ OR ΓΔ, PENTE-DEKA, FOR 5 x 10, OR 50;
ΓH, PENTE-HEKATON, FOR 5 x 100, OR 500;
ΓM, PENTE-MURIOI, FOR 5 x 10,000 OR 50,000

Therefore, in this notation

36,756 = MMMΓΧΓΗΗΓΠΙ

This system appears in records of the 3rd century B.C. but was probably used much earlier. In the 2nd century of our era it was described by the grammarian Herodianus, and hence these characters are often spoken of as Herodianic numerals. They are more properly called Attic numerals, being the ones always found in the Attic inscriptions.

Roman Numerals.—The direct influence of Rome for such a long period, the superiority of its numeral system over any other simple one that had been known in Europe before about the 10th century, and the compelling force of tradition explain the strong position that the system maintained for nearly 2,000 years in commerce, in scientific and theological literature, and in belles-lettres. It had the great advantage that, for the mass of users, the memorizing of the values of only four letters was necessary—V, X, L and C. Moreover, it was easier to see three in III than in 3, and to see nine in VIIII than in 9, and correspondingly easier to add numbers—the simplest of all the operations.

As in all such matters, the origin of these numerals is obscure, although the changes in their forms since the 3rd century B.C. are well known. Of the various theories that of Theodor Mommsen (1850) has had the widest acceptance. This was that the use of V for 5 is due to the fact that it is a kind of hieroglyph representing the open hand with its five fingers. Two of these gave the X for 10. Three of the other symbols, he asserted, were modifications of Greek letters not needed in the Etruscan and early Latin alphabet. These were *chi*, which appears in inscriptions not only as X but also in such forms as ⊥, ↓, and which later became the L that was arbitrarily chosen for 50; *theta* Θ, which was selected for 100, being finally changed to C under the influence of the word *centum* (hundred); and *phi* Φ, to which was assigned the value 1,000, and which finally took the forms I and M, the last being chosen because of the word *mille* (thousand).

The oldest noteworthy inscription containing numerals representing very large numbers is on the *Columna Rostrata*, a monument erected in the Roman forum to commemorate the victory of 260 B.C. over the Carthaginians. In this a symbol for 100,000, which was an early form of (((I))), was repeated 23 times, making 2,300,000. This illustrates not only the early Roman use of repeated symbols but also a custom which extended to modern times —that of using (I) for 1,000, ((I)) for 10,000, (((I))) for 100,000 and ((((I)))) for 1,000,000. The symbol (I) for 1,000 frequently appears in various other forms, including the cursive ∞. All these symbols persisted until long after printing became common. In the middle ages a bar (*vinculum, titulus*) was placed over a number to multiply it by 1,000, but this use is not found in the Roman inscriptions. When the bar appears in early manuscripts it was merely for the purpose of distinguishing numerals from nouns, as in the case IIVIR for *duumviri*. We also find in the middle ages such forms as $|\overline{X}|$ or $|X|$ for 1,000,000 and $|\overline{M}|$ for one thousand hundred thousand.

Of the later use of the numerals, a few of the special types are as follows:

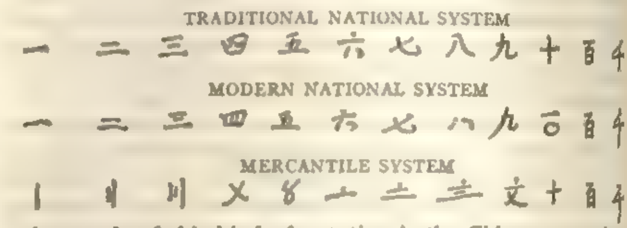
1. $\overline{c}$ · lxiiij · ccc · l · i, for 164,351, Adelard of Bath (*c.* 1120)
2. II.DCCC.XIIII, for 2,814, Jordanus Nemorarius (*c.* 1125)
3. MƆCLVI, for 1,656, in San Marco, Venice
4. cIↄ.Iↄ.Ic, for 1,599, Leiden ed. of Capella, 1599
5. IIIIxxet huit, for 88, a Paris treaty of 1388
6. four Cli.M, for 451,000, Baker's arithmetic (1568)
7. vj.C for 600 and CCC.M for 300,000, Recorde (*c.* 1542)

The first represents the use of the vinculum; (2) represents the place value as it occasionally appears in Roman numerals; (3) illustrates the not infrequent use of Ɑ (like D, originally half of (I), the symbol for 1,000); (4) illustrates the persistence of the old Roman form for 1,000 and 500, and the subtractive principle so rarely used by the Romans for a number like 99; (5) shows the use of *quatre-vingts* for 80, commonly found in French manuscripts until the 17th century, and occasionally later, the numbers often being written like iiij^{xx}, vij^{xx}, and so on; (6) represents the coefficient method, "four C" meaning 400, a method often leading to forms like ijM or IIM for 2,000, as shown in (7).

The subtractive principle is seen in Hebrew number names, as well as in the occasional use of IV for 4 and IX for 9 in Roman inscriptions. The Romans also used *unus de viginti* for 19 and *duo de viginti* for 18, occasionally writing these numbers as XIX (or IXX) and IIXX, respectively. On the whole, however, the subtractive principle was little used in the numerals of the classical period.

Multiplicative Grouping Systems.—In multiplicative systems special names are given not only to 1, b, b^2, etc., but also to the numbers 2, 3, . . . , $b-1$; the symbols of this second set are then used in place of repetitions of the first set. Thus if we designate 1, 2, 3, . . . , 9 in the usual way, but replace 10, 100 and 1,000 by X, C and M respectively, then in a multiplicative grouping system we should write 7,392 as 7M3C9X2. The principal example of this kind of notation is the Chinese numeral system, three variants of which are shown in Table II. In the traditional notation, 2,605 would appear as 二千六百五 (here written from left to right rather than vertically downward, as is customary). The modern national and the mercantile systems are positional systems, as described below, and use the circle O for zero.

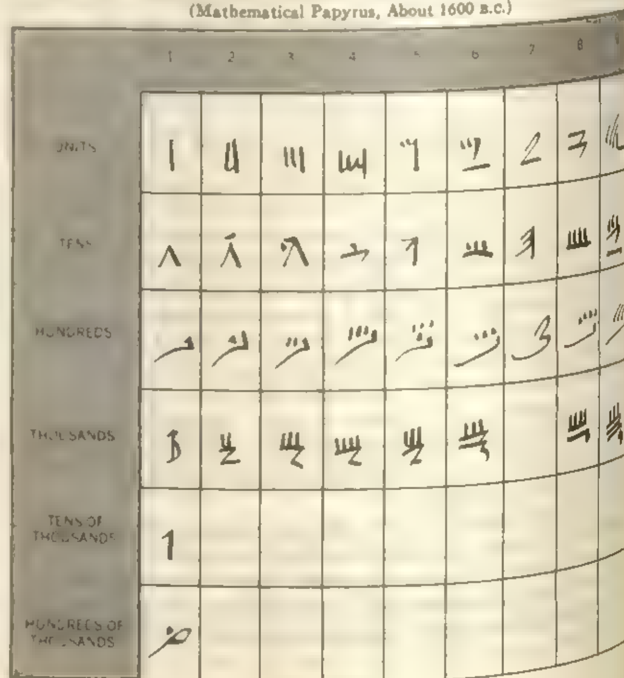
TABLE II.—*Chinese Numeral Systems*



Ciphered Numeral Systems.—In the ciphered systems, names are given not only to 1 and the powers of the base b but also to the multiples of these powers. Thus, starting from the artificial example given above for a multiplicative grouping system, we would obtain a ciphered system if we gave unrelated names to the numbers 1, 2, . . . , 9; X, 2X, . . . , 9X; C, 2C, . . . , 9C; M, 2M, . . . , 9M. This requires memorizing many different symbols, but it results in a very compact notation.

The first ciphered system seems to have been the Egyptian hieratic (literally, priestly) numerals, so called because the priests were presumably the ones who had the time and learning required to develop this shorthand outgrowth of the earlier hieroglyphic numerals. An Egyptian arithmetical work on papyrus, employ-

TABLE III.—*Egyptian Hieratic Numerals*
(Mathematical Papyrus, About 1600 B.C.)



ing hieratic numerals, was found in Egypt about 1855; known after the name of its finder as the Rhind papyrus, it provides the chief source of our information about this numeral system. With the symbols as indicated in Table III, the number 3,052 would be written (from left to right) as  (the customary way of writing was from top to bottom). There was a still later Egyptian system, the demotic, which was also a ciphered system.

As early as the 3rd century B.C. a second system came into use in Greece, paralleling the initial-letter system but better adapted to the theory of numbers and more difficult of comprehension by the trading classes. These Ionic, or alphabetical, numerals were simply a ciphered system in which nine Greek letters were assigned to the numbers 1–9, nine more to the numbers 10, . . . , 90, and nine more to 100, . . . , 900. Since, however, there were only 24 letters in the Greek alphabet, three were added, namely the Phoenician *vau* (shaped like our letter F), *koph*, *qoph* or *koppa* (shaped somewhat like our Q, and indeed derived from the same source) and a character known in modern times as *sampi* (then shaped somewhat like the Greek π, but tipped about 45° to the right, and represented here by S). The numerical values of the letters are shown in Table IV. The thousands were often indicated by placing a bar at the left of the numeral, thus:

TABLE IV.—*Ionic Greek Ciphered Numeral System*

	1	2	3	4	5	6	7	8	9
UNITS	A	B	Γ	Δ	E	[F]	Z	H	Θ
TENS	I	K	Λ	M	N	Ξ	O	Π	[Q]
HUNDREDS	P	Σ	T	Υ	Φ	X	Ψ	Ω	[S]

/A = 1,000; /B = 2,000; /I = 10,000; /T = 300,000

Such numeral forms were not particularly difficult for computing purposes once the operator was able automatically to recall the meaning of each. To be able to express 10,407 by MTZ would have seemed to a Greek considerably simpler than our system. Only the capital letters were used in this ancient numeral system, the lower-case letters being a relatively modern invention.

Other ciphered numeral systems include Coptic, Hindu Brahmi, Hebrew, Syrian and early Arabic. The last three, like the Ionic, are alphabetic ciphered numeral systems. The Hebrew system is shown in Table V.

TABLE V.—*Hebrew Ciphered Numeral System*

UNITS	א	ב	ג	ד	ה	ו	ז	ח	ט
	1	2	3	4	5	6	7	8	9
TENS	י	כ	ל	מ	נ	ס	ע	פ	צ
	10	20	30	40	50	60	70	80	90
HUNDREDS . .	ק	ר	ש	ת	ך	ם	ן	ף	ץ
	100	200	300	400	500	600	700	800	900

Positional Numeral Systems.—Our own number system is an example of the positional system, in which after the base b has been adopted, the digits $1, 2, \ldots, b-1$ are given special names, and all larger numbers are written as sequences of these digits. It is the only one of the systems that can be used for describing arbitrarily large numbers, since each of the other kinds gives special names to various numbers larger than b, and an infinite number of names would be required for all the numbers. The success of the positional system depends on the fact that, for an arbitrary base b, every number N can be written in a unique fashion in the form

$$N = a_n b^n + a_{n-1} b^{n-1} + a_1 b + a_0$$

where $a_n, a_{n-1}, \ldots, a_1, a_0$ are digits; *i.e.*, numbers from the group $0, 1, \ldots, b = 1$. We then represent N to the base b by the sequence of symbols $a_n, a_{n-1}, \ldots, a_1 a_0$. It was this principle which was used in the multiplicative grouping systems, and the relation between the two kinds of systems is immediately seen from the earlier noted equivalence between 7,392 and 7M3C9X2; the positional system derives from the multiplicative simply by omitting the names of the powers b, b^2, and so on, and by depending on the position of the digits to supply this information. It is then necessary, however, to use some symbol for zero to indicate any missing powers of the base; otherwise 792 could mean, for example, either 7M9X2 or 7C9X2.

The Babylonians developed (2000–3000 B.C.) a positional system with base 60—a sexagesimal system. With such a large base it would be awkward to have unrelated names for the digits 0, 1, . . . , 59, so a simple grouping system to base 10 was used for these numbers. For example,

$$256{,}058 = (60)^3 + 11(60)^2 + 47(60) + 38$$

In addition to being somewhat cumbersome because of the large base chosen, the Babylonian system suffered until very late from the lack of a zero symbol; the resulting ambiguities may well have bothered the Babylonians as much as later translators.

Mayan Vigesimal System.—In the course of early Spanish expeditions into Yucatan it was discovered that the Mayans, at an early but still undated time, had a well-developed positional system, complete with zero. It seems to have been used primarily for the calendar rather than for commercial or other computation; this is reflected in the fact that although the base is 20, the third digit from the end does not signify multiples of 20^2 but of 18×20, thus giving their year a simple number of days. The digits 0, 1, . . . , 19 are, as in the Babylonian, formed by a simple grouping system, in this case to base 5 (*see* Table VI); the groups were written vertically.

TABLE VI.—*Mayan Vigesimal Number System*

The Concept of Zero.—Neither the Mayan nor the Babylonian system was at all suited to arithmetical computations, because the digits—the numbers less than 20 or 60—were not represented by single symbols. The complete development of this idea must be attributed to the Hindus, who also were the first to use zero in the way it is now used in the western world. As was mentioned earlier, some symbol is required in positional number systems to mark the place of a power of the base not actually occurring. This was indicated by the Hindus by a dot or small circle, which was given the name *sūnya*, the Sanskrit word for vacant. This was translated into the Arabic *sifr* about 800 A.D., with the meaning kept intact, and the latter was transliterated into Latin about 1200, the sound being retained but the meaning ignored. Subsequent changes have given us our words cipher and zero.

A symbol for zero appeared in the Babylonian system in about the 3rd century B.C. However, it was not used consistently, and apparently was used only to hold interior places, never final places, so that it was impossible to distinguish between 77 and 7,700, except by the context.

DEVELOPMENT OF MODERN NUMERALS AND NUMERAL SYSTEMS

Several different claims, each having a certain amount of justification, have been made with respect to the origin of our present numerals, commonly spoken of as Arabic but preferably as Hindu-Arabic. These include the assertion that the origin is to be found among the Arabs, Persians, Egyptians and Hindus. It is not improbable that the intercourse among traders served to carry such symbols from country to country, so that our numerals may be a conglomeration from different sources. The country, however, which first used, as far as we know, the largest number of our numeral forms is India. The 1, 4 and 6 are found in the Aśoka (*q.v.*) inscriptions (3rd century B.C.); the 2, 4, 6, 7 and 9 appear in the Nānā Ghāt inscriptions about a century later; and the 2, 3, 4, 5, 6, 7 and 9 in the Nasik caves of the 1st or 2nd century of our era—all in forms that have considerable resemblance to our own, our 2 and 3 being well-recognized cursive derivations from the ancient = and ≡. None of these early Indian

inscriptions gives evidence of place value, or of a zero that would make our place value possible. Hindu literature gives evidence that the zero may have been known before our era, but we have no inscription with such a symbol before the 9th century.

The first definite external reference to the Hindu numerals is a note by Severus Sebokht, a bishop who lived in Mesopotamia *c.* 650. Since he speaks of "nine signs," the zero seems not to have been known to him. By the close of the 8th century, however, some astronomical tables of India are said to have been translated into Arabic at Baghdad, and in any case the numerals became known to Arabian scholars about this time. About 825 al-Khwarizmi wrote a small book on the subject, and this was translated into Latin by Adelard of Bath (*c.* 1120) under the title of *Liber Algorismi de numero Indorum*. There is some reason for believing that the numerals found their way into Europe even earlier than into Baghdad, but the earliest European manuscript known to contain them was written in Spain in 976.

The advantages enjoyed by the perfected positional system are so numerous and so manifest that the system has gradually been adopted in more and more countries, and because of the dominance of Europe in cultural and political matters, the Hindu-Arabic numerals and the base 10 are now also generally accepted. These might be said to be the nearest approach to a universal language yet devised by man; they are to be found in Chinese, Japanese and Soviet scientific journals, and in English, German and Greek.

There is one island in present-day life, however, in which the familiar decimal system is no longer supreme: the electronic computer. Here the binary positional system has been found to have great advantages over the decimal. In the binary system, in which the base is 2, there are just two digits, 0 and 1; the number two must be represented here as 10, since it plays the same role as does ten in the decimal system. The first few numbers are

$$
\begin{aligned}

To return to the example used before, 256,058 has the binary representation 111 11010 00001 11010. The reason for the greater length of the binary number is that a binary digit distinguishes between only two possibilities, 1 or 0, whereas a decimal digit distinguishes among 10 possibilities; in other words, a binary digit carries less information than a decimal digit. Because of this its name has been shortened to bit; a bit of information is thus transmitted whenever one of two alternatives is realized in the machine. It is of course much easier to construct a machine to distinguish between two possibilities than among 10, and this is another advantage for the base 2; but a more important point is that bits serve simultaneously to carry numerical information and the logic of the problem. That is, the dichotomies of yes and no, and of true and false, are preserved in the machine in the same way as 0 and 1, so in the end everything reduces to a sequence of those two characters. *See* also BINARY NUMBERS; FINGER NUMERALS.

NUMERIAN (MARCUS AURELIUS NUMERIUS NUMERIANUS), Roman emperor A.D. 283–284, succeeded his father, Carus, in the summer of 283, in the midst of a Persian war, beyond the Tigris. He led the army home, but contracted a disease of the eyes, which confined him to a litter, while his father-in-law, the praetorian prefect Aper, commanded the army. Late in 284, when the army had reached the Bosporus, he was found dead. Aper was accused of his murder and executed, and the throne passed to the commander of the household guards, Diocletian (*q.v.*). (JN. R. M.)

NUMIDIA, the Roman name of part of Africa north of the Sahara with varying boundaries in the east and west, at times corresponding roughly with those of modern Algeria. (For the physical geography of the region *see* ALGERIA.) Its earliest inhabitants were divided into tribes and clans and were racially indistinguishable from the other Berber inhabitants of most of early north Africa. Little can confidently be said of its prehistory, as it was isolated from the mainstream of Mediterranean history. From the 6th century B.C. points along the coast were occupied by the Carthaginians, who later, in the 3rd century B.C., expanded into the interior as far as Theveste (Tebessa).

Numidians are frequently found in Carthaginian armies. They remained seminomadic and backward, however, till the reign of Masinissa (*q.v.*), who was the chief of the tribe called Massyli living near Cirta (Constantine). At first an ally of Carthage, he went over to the Roman side in 206 B.C. and was given further territory extending as far as the Mulucha (Moulouya) river. For nearly 50 years Masinissa retained the support of Rome, though it was the prosperity of Carthaginian agriculture that was his inspiration in his efforts to settle the Numidian pastoralists as peasant farmers. He seized much Carthaginian territory and probably looked forward to ruling all north Africa.

On his death in 148 the Romans prudently divided his kingdom among several chieftains, but the progress of civilization among the Numidians was not seriously interrupted; indeed after 146 it received new impetus as thousands of Carthaginians fled to Numidia after the destruction of Carthage. Politically the situation deteriorated after 118 with the usurpation of Jugurtha (*q.v.*), an illegitimate prince, and his forcible reunification of Numidia. He avoided Roman intervention by bribery and intrigue until he overreached himself by killing Italian immigrants at Cirta. After a war of varying fortunes he was surrendered to the Romans by Bocchus of Mauretania in 105. Rome continued to dominate Numidia through client kings, though Numidian territory was much reduced. The third and final attempt by a Numidian to found a powerful state was that of Juba I, between 49 and 46 B.C., ending with his defeat by Julius Caesar at Thapsus.

Caesar formed a new province, Africa Nova, from Numidian territory, making a boundary between it and Mauretania along a line running roughly southwest from the mouth of the Ampsaga (Wadi al Kebir) to the Chott al Hodna. Augustus united Africa Nova with Africa Vetus but Caligula made the commander of the third legion (*legio III Augusta*) virtually independent of the proconsul of Africa, with jurisdiction over most of the old Numidian territory; a separate province of Numidia was formally created by Septimius Severus. Italian immigration was on a modest scale except in the northern part of the territory, where supporters of Caesar had been given lands; the chief cities there were Cirta, Cuicul (Djemila), Milev (Mila) and Rusicade (Philippeville).

In the 1st century A.D. the nomads of the steppe country south of Cirta were pacified and the Aurès mountains were encircled by roads. The third legion took up its permanent station at Lambaesis (Lambessa), near which grew up cities with substantial veteran elements such as Thamugadi (Timgad), Mascula (Khenchela) and Diana Veteranorum (Zana). As a result of increased security the population and prosperity (primarily agricultural) of Numidia increased substantially in the first two centuries A.D. But while a modest number of native communities advanced to municipal status, the majority of the population, particularly the peasants on the large estates and in the mountainous areas, were little touched by Roman civilization.

Christianity spread rapidly in the 3rd century A.D., and in the 4th, Numidia became the centre of the Donatist schism (*see* DONATISTS). This movement had a fanatical and puritanical outlook and was particularly strong among the peasants, to whom it appealed as a focus of protest against deteriorating social conditions; it also had a substantial following among the intelligentsia. Imperial repression merely drove the movement underground. Some cities still enjoyed some prosperity but Numidia suffered from the malaise affecting the whole empire. After the Vandal conquest (A.D. 429), Roman civilization declined rapidly and the native elements revived, to outlive in some places even the tide of Arabic conquest in the 8th century and to persist till modern times.

NUMISMATICS (an 18th-century term derived from the Latin *numisma* and Greek *nomisma*, "a coin") is the study of coins, including medals but excluding seals. A coin may be defined as a piece of metal stamped with a "type," *i.e.*, device, or inscription showing that it is issued by an authority that guarantees its value. Paper money, which serves the same purpose, is sometimes considered to be a part of numismatics also. Aesthetic and commemorative medals are produced by the same methods as coins and are discussed here; for military decorations *see* MEDALS AND DECORATIONS. This article is divided into the following main sections:

I. INTRODUCTION

1. The Scope and Materials of Study.—Coins or coinlike objects were first issued in Asia Minor in the later 7th century B.C. and in the far east at about the same time. Their use was quickly adopted around the Mediterranean and has since spread over the whole civilized world. Being made in most ages of precious metal, or alternatively possessing a substantial token value, they have always been prized, often hoarded and, therefore, frequently buried for safety. The contents of such savings banks have been dug up in all ages, and not least by modern mechanical excavators and deep plows, so that the coins of past civilizations exist and continue to be found in vast numbers preserved, almost imperishably, out of all proportion to most other generally surviving remains. Studied alongside other evidence, literary or archaeological, they yield a wide range of information, which, though its importance can be exaggerated or misinterpreted in isolation, is specially valuable for chronology and economics. Coins may reflect the wealth and consequence of cities and states, and study of their distribution may help to define the physical extent of territorial dominion (as with the coinage of the kings of pre-Roman Britain) or to illustrate major commercial connections in a known chronological setting. Thus the popularity in ancient times of Athenian silver tetradrachms in the Levant and of Corinthian silver staters in Magna Graecia testifies to established trends of trade at definite periods; the finds of early Roman imperial gold in India corroborate Pliny's reference to the drain on Roman gold to pay for Indian and other eastern luxuries; and the huge finds of Arab silver coins in Scandinavia show the extent of trade for furs on behalf of the wealthy Abbasids and Samanids. One result of such widespread commercial contacts is that certain currencies have acquired special international preeminence. In ancient times those of Athens, Corinth and Philip II of Macedon were widely popular; so, in medieval times, were the gold dinars of the early caliphs and the gold ducats of Florence and Venice, while in modern times the silver dollars of Mexico and Maria Theresa of Austria and the gold sovereigns of England have played a similar part. The economic importance of numismatics is seen also in moments of national decline, when depreciation reflects financial stress; the heavily alloyed Roman antoniniani of the 3rd century A.D. tell their tale as readily as the inflated paper currency of Germany in and after 1919.

No less valuable than the economic evidence yielded by a comparative study of coins is their purely documentary importance, which may be more absolute. Together with medals they present an unrivaled series of historical portraits from the 4th century B.C. down to the present day, many of them otherwise unknown, like those of the Greco-Bactrian kings or of usurpers during the Roman empire. Greek coinage is a particularly notable contribution to the history of art, displaying not only the beauty and strength of many artistic traditions but also (like Roman coinage) the miniature likenesses of numerous large-scale sculptural and architectural works now lost. The imperial coinage of Rome, apart from its portraiture, is important above all for the remarkable detail of its chronological and political content; and from both Greek and Roman coins very much can be learned of mythology and religion. The Christian influences active in medieval Europe can be similarly measured from medieval currencies, beginning with that of Byzantium.

The principal metals of which ancient coins were made were electrum, gold, silver, copper, brass and bronze, all of them more or less proof against decay. Their use at first was generally dictated by availability. The earliest coins of Asia Minor were of electrum, a natural alloy of gold and silver (later to be produced artificially) washed from Lydian rivers; gold became the major currency metal of southwest Asia as a whole, being derived from Scythian, Pontic and Bactrian sources; the city-states of the Greek mainland preferred the silver that adjacent mines supplied; and

the mines of Italy led to the choice of bronze for the earliest coinage of Rome. With the development of internal economies and external trade, gold, silver and copper or bronze quickly came to be used side by side; Philip II of Macedon popularized gold in Greece, and gold, together with silver, competed strongly with copper in the Roman imperial currency, becoming paramount in the Byzantine and Arab empires and in the great commercial currencies of the Italian republics of the 13th century onward. Silver, however, was nearly always powerful in Roman currency and was the major coinage metal of Europe from the 8th to the 13th century. Bronze or copper was first used for small change in Greece from the late 5th century B.C., and in the Roman and Byzantine systems as well; the vast currency of China consisted of these metals down to modern times.

The foregoing metals furnished most currencies until the early 20th century, when the appreciation in value of gold and silver and the need to economize led to the general production of paper currencies for the higher units of value, accompanied by token units of lower value expressed in terms of nickel (used, exceptionally, in Bactria in the 3rd century B.C.), cupronickel, bronze and, in times of postwar stress, aluminum and aluminum bronze. Few coins of pure silver are now to be found in Europe or the British Commonwealth as a whole. Lead, which may easily decay, has seldom been used for coinage, except by the Andhras of ancient India and in the more recent coinages of the Malay States. Iron, very occasionally used in antiquity, *e.g.*, in Sparta, reappeared in German coins of World War I. Zinc was employed by Rome as a constituent of fine brass coins and as an element in the alloy of a few Chinese coins from the 15th to the 17th centuries. Tin, or a tin-bronze alloy, furnished the material for some Celtic coins in Gaul and Britain in the last century B.C. In times of siege or special crises, currencies have been produced from leather, cloth, card, paper, etc.

2. Coin Collections.—The enormous number of coins produced from the earliest days has for a long time resulted in organized collecting, partly because of the natural curiosity felt in each period about the past and partly because of the recognition that the political, economic and artistic significance of previous coinages can be reconstructed only by the most complete assemblage possible. The continuous history of coin collecting begins with the Italian Renaissance, and Petrarch was characteristic of his time in forming a classical series. During the 15th and 16th centuries many collections were made, often on a handsome scale, by princely or noble persons, for whom Greco-Roman coins possessed an appeal compounded of moral challenge and artistry. Among the more famous cabinets were those of Jean, duc de Berry; of the d'Este family; of the emperor Maximilian I; and of Matthias Corvinus. The two last collections became the nuclei respectively of the present national collections of Austria and Hungary; later the cabinet of Louis XIV was to serve France similarly, just as that of the Stuarts might have served England but for its dispersal in the Puritan revolution. Collections formed up to the 17th century consisted mainly of classical coins. The systematic reproduction of the types of ancient coins either by casting or from falsified dies resulted in the inclusion in most cabinets of spurious and often imaginative pieces.

The 17th century initiated a period of systematic analysis; numismatic scholars set out to compare, catalogue and publish the existing great collections, both public and private. Italy possessed over 350, France and the Low Countries about 200 each and Germany not many less. Thus the self-imposed task of such a compiler as André Morell, in undertaking the detailed recording of 25,000 ancient coins, was formidable; he and his like traveled from place to place in search of material at once massively and often uncritically accumulated. The advent of such compilations had important results. Distinction between the genuine and the spurious became surer; analytical syntheses based on detailed catalogues began to teach the principles of scientific numismatics; the recording of new material was all the more keenly undertaken; and the part played by numismatic evidence in historical reconstruction was increasingly understood, even within the still inevitable limitations of faulty knowledge or misinterpretation.

From the 18th century onward it was therefore all the more important to collect on a scale at once wide and discriminating; and whether in charge of a royal cabinet, like the eminent Joseph Eckhel (1737–98) at Vienna, or the possessor of a splendid private collection, like William Hunter (1718–83) at Glasgow, the 18th-century collectors made a great contribution. Lesser collectors could also advance the science; their numbers were to grow in the 19th century, with the output of authoritative catalogues (including the British Museum series from 1873) and informed handbooks. This growth was reflected in the foundation (beginning in 1836 with the Numismatic Society of London, now the Royal Numismatic society) in many European countries of specialist societies responsible for scholarly publications. But the day of the great private collection was not yet done: superb cabinets were formed in the late 19th century, and that of R. C. Lockett in the 20th bore comparison with all except the greatest museum collections. In general, however, the small collections of the 20th century, enormously increased in numbers, have had to specialize somewhat narrowly to achieve scientific value. Public museums have taken over the main task of forming large collections of great detail and range; those of London, Oxford, Cambridge, Glasgow, Paris, Berlin, Vienna, Munich and New York are among the richest. Nevertheless an essential link has remained between the large public collections and the smaller private collector, whose sharp eye and keen curiosity continue to be responsible not only for a considerable influence upon taste but also (far more important) for the discovery or recognition of many key pieces of historical importance.

London emerged, and still remains, the world's largest numismatic market (with an annual turnover of immense value), serving the interests of public collections and private collectors in many lands. Inasmuch as these interests are, jointly, directed increasingly toward the systematic elucidation of historical and economic problems, international co-operation has become more important, being exercised through the International Numismatic commission, itself associated with the International Committee for Historical Sciences. But below this apex there spreads out a vast body of private collectors in many lands, whose interests may often have been stimulated in childhood by the chance gift or discovery of a handful of coins.

3. Technique.—The technique of producing coins and medals has developed continuously from earliest times; and, though machinery has diminished creative aspects in design, the artist's part in making relief designs has never been eliminated. Hand and eye, jointly, remain supreme.

The two methods of producing coins and medals are casting and striking. Casting, technically simplest but seldom employed in antiquity for regular coinage, was the method preferred by all the greatest Renaissance artists, from Pisanello in the 15th century onward, for the production of medals larger and more sensitive than striking would permit. A model was built up (or carved out) in wax or clay and then impressed in a mold of fine sand or other material, from which a metal cast could be taken. German artists, to eliminate the subsequent chasing allowed by Italians, often carved their model in hardwood or fine stone, or even sometimes intaglio in clay, afterward baked. Many medals apparently of the 15th or 16th century are after-casts of the original casting their detail coarsened by continuous reproduction. Plaquettes (small decorative reliefs, not commemorative, generally single faced and rectangular) are also cast from molds.

A coin or medal is struck when a metal blank, placed between engraved dies, is then impressed by hammerblows or other pressure. Modern dies are of hardened steel. Even in ancient times they had to be of specially hard metal: the Greeks used bronze, the Romans also iron or even steel. A die can be hand cut directly, like an intaglio gem. Or a positive punch can be carved in relief and the design then hammered intaglio into softer metal afterward hardened. A curious combination of dies in intaglio and relief is seen in the coinages of certain south Italian Greek cities in the late 6th century B.C. and also in the thin medieval bracteates of Germany. Some early medieval Muslim dies were probably cast in bronze or iron from lead or clay matrixes and

18TH- AND 19TH-CENTURY NORTH AMERICAN COINS

1. Spanish-American gold ingot issued under the reign of Philip V and bearing his stamp. Minted in Mexico City and dated 1744. 2. Gold coin-ingot issued by the Jesuits in 1707 at their Tubac mission in Arizona. 3. Fifty-dollar piece (1851) authorized by Augustus Humbert, U.S. Assayer, and minted by Moffat and Co., San Francisco, Calif. 4. Fifty-dollar piece (1853) of the U.S. Assay Office of Gold, successor to Moffat and Co. and immediate predecessor of the federal branch mint at San Francisco. This is the only specimen extant. 5. Fifty-dollar piece (1855) of Kellogg and Co., another private mint in San Francisco. Dies were made by Ferdinand Gruner. Only 13 specimens known. 6. Fifty-dollar piece (1855) of Wass, Molitor and Co., another private mint in San Francisco. 7. Two hundred-dollar ingot (1853) of the U.S. Assay Office of Gold, San Francisco. The illustration is of the only known example

then chased and hardened. Engravers' instruments in antiquity were the graver and dotting punch (seldom, perhaps, the drill); rock crystal could supply the magnifying glass that extraordinary fineness of work often necessitated. Medieval engravers made great use of letter and other punches in die-cutting. Modern dies are generally prepared by the operation of the reducing machine (since *c.* 1839) upon a large-scale metallized model, producing an exact small-scale facsimile capable of being used as a master punch.

Ancient blanks were cast, often in globular form. They could also be cut from bars. Thin medieval blanks were clipped from sheet metal; modern ones are punched from strips. In antiquity the lower die, for the obverse, was let into a fixed block; the upper die was the termination of a loose bar. The blank was placed on the fixed die, the loose die placed upon the blank, and the top of the bar hammer-struck with one or more blows. Lack of a "collar" allowed metal to spread or split, and the loose die was quick to wear out. The Romans tended to arrange their dies in a fixed relationship, presumably by interlocking box-dies; a similar use of pegs and slots may have been common medieval practice. Under Pope Julius II (1503–13), Bramante experimented with a press for lead seals. Leonardo da Vinci made progress toward a coining press, and the screw press was duly evolved; substitution of gradual pressure instead of a violent blow upon the dies and the blank resulted in a much longer life for dies and in coins of neater fabric, especially after the development of the "collar." For further discussion of modern coinage, *see* MINT.

In design, the high relief of Greek and earlier Roman coins, though subject to wear in circulation, encouraged a sculptural treatment, in which lettering took a minor part. Late Roman, Byzantine and medieval coins show a flat treatment, typical of modern coins, in which lettering became more important; its finest use is seen in the purely inscriptional types of Arab and Persian coins. The problem of composing within a circular field was variously solved at different times, as will be seen in the following survey by countries.

4. Origins of Coinage.—In both east and west, coinage proper was preceded by more primitive currencies, nonmonetary or semimonetary, which survived into the historic age of true coins. At all times barter has been a valued means of exchange, not least because it is capable of expressing small as well as large values conveniently, and in the absence of a good system of small change it has probably always been vigorous. But even in ages of barter certain standards of value have tended to emerge, notably cattle and implements, and these often became or suggested a medium of exchange. The earliest currency of China of the 8th century B.C. consists of miniature spades and billhooks, with an inscription indicating the authority. The small bronze celts frequently found in hoards in western Europe probably played a monetary role. Even in modern times such things as fishhook currency have been known.

Metal has always achieved wide popularity as an exchange medium, being durable, divisible and portable; and the origins of true coinage lie there. Ancient Egypt, which never developed a true coinage, was using gold bars of set weight from the 4th millennium B.C.; and the currency of gold rings was thereafter common. In the near east also, which (like Egypt) had access to gold, gold rings long served the dual purposes of adornment and currency, supplemented by gold and silver bars from which segments could be cut. The choice of metal was, as usual, suggested by availability. Around the Aegean sea heavy talents of copper, ingots of 25 kg. or more in weight, were in currency several centuries before true coinage, and the discovery of an iron bar with a handful (*drachma*) of fractional iron spits (*obeloi*) dedicated in the Heraeum at Argos, perhaps as part of Pheidon's metrological reforms, shows such currency continuing until historical times. Similar bundles of spits have been found elsewhere and are evidence for the desire to subdivide a heavy and cumbrous unit into smaller fractions for normal use. At the other end of the scale there was, ultimately, the desire to express the value of a talent of copper or iron in terms of gold or silver; and Homer, who speaks of metal basins, tripods and axes as gifts and prizes in a way that shows them as a recognized standard of wealth, also speaks of the talent of gold; *i.e.*, the value of a heavy base-metal talent expressed in a little pellet of gold. In Italy rough lumps of bronze (*aes rude*) formed a currency from early times, being succeeded by stamped bars of regular weight; and Caesar's record of the ancient British use of iron bars as currency is still borne out by not infrequent finds.

Such "heavy" currencies, mainly characteristic of European lands, show the employment of metals from which implements would normally be made. The impact upon this system of the gold of the east, and later of the silver of Greece, produced the need to value such metals in gold and silver, and this in turn resulted in the need to control and guarantee the quantity of gold and silver so used, to avoid constant weighing. Once gold (and then silver) gained acceptance as conveniently small expressions of relatively high value, with a visible mark of guarantee, the stage of true coinage, as it first appeared in Asia Minor and India, had been reached. Not all lands, however, adopted true coinage: the easternmost fringes of the Greek world lacked it, and so too Egypt, until the conquering Ptolemaic dynasty introduced it. Finds of Greek coinage in such areas, chopped and gouged and partly melted, show that the imported coinage of others was still accepted there as mere metal bullion. Carthage and Etruria were likewise without coinage until the 5th century.

II. GREEK COINS

1. Early Development, *c.* 650–490 B.C.—True coinage began soon after 650 B.C. Ancient writers—the 6th-century Xenophanes quoted in the 5th by Herodotus—ascribed its invention to the Lydians, "the first to strike and use coins of gold and silver." This statement, however, best refers to the action of Croesus of Lydia (560–546 B.C.) in producing a bimetallic system of pure gold and pure silver coins. The coinage he displaced was of electrum, the natural mixture of gold and silver that the Greeks called "white gold"; and the foundation-deposit of the Artemisium at Ephesus shows that electrum coins were being made about a century before Croesus—though not, as was once held, before 650 B.C. This early electrum coinage, which was current in Lydia and Ionia, and possibly in other adjoining areas of Asia Minor, consisted of small, thick, bean-shaped pieces, with a device stamped in relief on one side, the other side being roughly impressed. Their intrinsic value fluctuated according to their gold and silver content; but the weight of the unit was fairly steady around seven to eight grams, and the types stamped on them are the guarantee of authority. The earliest coins of Croesus were similarly of electrum, stamped on one side with the facing heads of a lion and a bull; and this type was duly transferred to his bimetallic series of pure gold and pure silver.

Croesus' relations with Greece were close, and his bimetallic system may have owed something to the fact that Greece had itself now produced its first silver coins. The oldest are of Aegina, with, obverse, a turtle—associated with Aphrodite—and, reverse, an incuse square. Tradition, *e.g.*, in Pollux and elsewhere, regarded these as struck by Pheidon of Argos in virtue of his supremacy over Aegina; but the coins are too late to claim association with him in Aegina. They began no earlier than the late 7th century, when Aeginetan maritime ascendancy was growing, incidentally spreading the Aeginetan weight standard for coinage, based on a drachma of about six grams, over much of the Peloponnese and also the Aegean, where similar currency was produced in the islands. Ambition and pride stimulated two neighbouring powers to strike their own coins. Corinth with its "pegasi" (from their constant obverse type of a pegasus) was coining silver from *c.* 575 with a light drachma of about 3 g., and it is reasonably certain that in Athens in the first half of the 6th century Attic coins, based on a drachma of about 4.25 g. derived from Euboea and with a variety of obverse types, including an owl (the reverses, like those of the Corinthian pegasi, were impressed with a punch), were supplanting the earlier coinage of Aegina. These early silver coins, while much less valuable intrinsically than the electrum and gold coins of Asia Minor, nevertheless possessed considerable purchasing power: the Aeginetan and Attic-Euboic didrachms and

the Corinthian tridrachm were high denominations suitable for major commerce and not for everyday life. For intercity transactions these "staters," *i.e.*, standard units, were conveniently linked by the mina weight ($\frac{1}{60}$ of a talent) of 425 g., made up by 150 Corinthian, 100 Attic and 70 Aeginetan drachmas. Fractional pieces developed only slowly.

Between 550 and 500 the practice of coinage had spread to many parts of the Greek world, usually out of commercial convenience, though also partly to satisfy civic pride. From the Persian empire, with its vast gold and silver coinage, successor to that of Croesus, to Magna Graecia and Sicily, and from the Dorian colony of Cyrene, rich in the cultivation of silphium, to the Greek or semi-Greek cities of Thrace, there was a network of varied and competitive currencies, generally of fine quality and steady weight. Improved minting techniques began to affect their appearance. A second type, in relief, was substituted gradually for the roughly impressed reverse punch. The important effect of this on the development of coin types is well seen in the reorganized coinage of Athens from *c.* 525, in which the obverse bears the Athena head and the reverse the owl of Athens—religious patron and civic device; the monarch's head on an English penny goes back, through Alexander's deified head, to the head of Athena, and the symbol of Britannia derives ultimately from such state badges as the owl. In certain cities of Italy and Sicily, however, including Tarentum and Metapontum, a different technique was popular, the obverse type in relief being repeated intaglio on the reverse, very probably with the object of concealing the older types of coins imported for restriking. For a long time the early coins of Greece carried no inscriptions or, at most, with very rare exceptions, a letter or two. The type of a seal (φώκη) at first indicated Phocaea without even the later explanatory Φ; a koppa (ϙ) was sufficient to add to the pegasi of Corinth; ΣΥ could indicate Sybaris, while ΑΘΕ was comparatively explicit for Athens. That the force of such abbreviated ethnics is genitival, referring to the coin and its badge, is shown by the form of longer legends. These are very rare on early coins: *I am the badge of the bright one* above a stag on a group of electrum coins from Ephesus, *the stamp of Gortyna* on an early Cretan coin. Later usage was to favour the simple genitive plural, fully expressed, *e.g.*, Συρακοσίων, though the nominative was not unknown.

Greek coin types, early and even later, were simple in conception and often taken from the animal world. They include many kinds of animals (with the bull, symbol of a river, very common); birds (such as the owl of Athens, the eagle of Zeus at Olympia, the dove at Sicyon); insects (like the bee of Ephesus); fabulous creatures (like the griffin at Abdera); and vegetable objects. Not uncommonly such types were chosen as punning allusions to a city's name—the lion at Leontini, the goat at Aegae, the quince at Melos, the sickle-shaped harbour at Zancle, the *selinon* leaf at Selinus, the cock, harbinger of *hemera*, the day, at Himera. In others a city's staple product was proclaimed, like silphium at Cyrene, a silver-miner's pick at Damastium, a bunch of grapes at Naxos, a wine jar at Chios. Frequently cult associations dictated the choice of type. Tarentum showed its mythical founder, the dolphin rider Taras; Cnossus the Minotaur or Labyrinth; Croton the tripod of Apollo; Poseidonia a statue of Poseidon. Human or anthropomorphic figures, however, were comparatively rare on early Greek coins, though the famous gold darics and silver shekels of Persia showed the Great King in the attitude of attack. Much more popular was the representation of idealized heads of deities, which, once established for the two Athenas, Parthenos and Chalinitis, at Athens and Corinth, quickly became the vogue elsewhere, encouraged as they were by the development of double-relief coinage, which allowed the head of a civic deity to be paired on the other side by the city's symbol. The Greek tyrants, as a rule, chose to respect the theory of coinage as the corporate expression of state economy: the famous tetradrachms of Athens, with, obverse, Athena head and, reverse, owl, were first made by a nondemocratic government and yet bore no reference to a tyrant's rule. Coinage, indeed, was from the first (with the possible exception of some of the earliest electrum) regarded as too important a matter for private production, and the traditions that, rightly or wrongly, associated all the great lawgivers, Pheidon, Solon and Lycurgus, with the institution of coinage as well as with reform of weights emphasize its position as a fundamentally corporate right.

In Sicily the defeat of Carthage in 480 B.C. was fittingly celebrated by the striking of the famous decadrachms (*Demareteia*) associated with Queen Demarete, wife of King Gelon. These superb and now very rare examples of early classical genius showed on the obverse the head of Arethusa (the fountain nymph of Syracusan Ortygia), wreathed for victory, and on the reverse a triumphal chariot above a fleeing lion, symbol of conquered Africa.

2. From the Persian Wars to Alexander the Great, 490–336 B.C.—For a century and a half the previous pattern of Greek coinage spread widely all over the Greek world, its quantity stimulated by a growing sense of nationalism, its intrinsic quality kept high by commercial competition, and its technique (like that of the allied art of sculpture) raised to new and often superb levels in an age of self-confidence. In the last half of the period the designing and engraving of coin dies reached a standard seldom if ever to be surpassed. The head of a patron deity was now generally established as the obverse type and was often shown in very high relief, sometimes indeed facing, or nearly facing, as a tour de force. Engravers, especially in Sicily and Italy, began to sign their dies, indicating a status far above that of mere artificers and thus preserving the names of masters otherwise unknown. Reverse types, now more complex, increasingly showed groups or genre scenes, *e.g.*, the splendid frontally squatting Silenus on the coinage for the refounding of Sicilian Naxos in 461, or Dionysus seated backwards on a donkey at Mende, or the many mythological compositions on Cretan coins, often diminishing the previous importance of the city badge. Inscriptions, though still often contracted, were in general use. The principal coinage metal was silver, of which the Attic weight standard gradually conquered the Aeginetan. Electrum was continued in the east, at Cyzicus, Lampsacus, Mytilene and Phocaea, traveling thence mainly to the Black sea; in the west it was coined at Carthage. In both areas it was produced as an artificial alloy. Gold was continued in the darics of the Persian kings and in the fine later series of Lampsacene staters; it was also struck at Panticapaeum in the Black sea and on occasion at Syracuse, Tarentum and Cyrene. Toward the end of the period Philip II of Macedon instituted what was to be a world-famous gold coinage, undercutting and ousting that of Persia. Bronze made its appearance late in the 5th century as a substitute for the minute silver coins that had hitherto been increasingly necessitated as small change.

The currencies of the period included a few that were of world importance. The silver of Corinth and her Adriatic colonies was very numerous and was abundantly accepted, outside the Corinthian territories, by Italy and Sicily. The electrum of Cyzicus bore types that deliberately recommended it to many markets. Persian gold and silver coins enjoyed immense popularity in the 5th century. Metapontum, Tarentum, Thurium, Velia and Syracuse were among the more prolific silver mints of the west. But the most famous commercial currency of all was that of Athens, the silver tetradrachms of which were struck in large numbers, fine quality and obstinately unchanged appearance. These coins traveled widely in trade and were frequently hoarded outside Attica itself; moreover they received the compliment of imitation in distant areas, *e.g.*, Egypt, Arabia and Persia, which came to prize them for their reliable weight and quality.

Predominance of Athens.—The economic expansion of Athens in the late 6th century was greatly stimulated in the early 5th notably by the exploitation of richer veins in the Laurium silver mines. Athens' naval hegemony in this century crystallized in the Confederacy of Delos and developed into near-imperial control, economic as well as political, over her allies; and it may have been as early as 449 that Athenian edicts forbade the striking of silver coins by the allies or the use of currency, weights and measures other than the Athenian, and provided that previously minted local currencies should be handed in for exchange against that of Athens. The subjection of Aegina to Athens from 456 and the cessation of her famous and long competitive "turtles" facilitated

the monetary dominance of the "owls," which was carried further, stage by stage, as Athenian "allies" revolted, were reconquered and lost their independence. But the embargo put by Athens on local silver coinage was not absolute and perhaps was not expected to be. Major allies like Samos, Chios and Lesbos continued their own currencies; Phocaea, Mytilene and Cyzicus, though ceasing to coin in silver, continued with electrum. In other cities, small change in silver was issued. Beyond the effective range of Athenian power, cities in Pamphylia, *e.g.*, Aspendus, and in Thrace, *e.g.*, Abdera and Aenus, could continue silver coinage on a non-Attic standard, and the failure of Athenian control is seen in the sudden and often beautiful coinages of cities that threw aside its dominance, like Olynthus from *c.* 430, or in the changed weight standard of others; *e.g.*, Acanthus. During the Peloponnesian War, Sparta cut off the supply of silver from Laurium, and by 407 Athens was melting the gold Nikai from the Parthenon to make emergency coins, followed next year by bronze small change —an unpopular substitute for the tiny silver coins previously carried in the mouth. City after city now rebelled against Athens, and there was a sudden burst of independent coinage.

Athenian coinage revived, with unchanged types, after Conon's successes in 394. But former allies were wary, and defensive leagues were formed, as shown by the coinage issued at that time, with a type of Heracles and the inscription ΣΥΝ(*μαχικόν*) ("the alliance"), by Cnidus, Ephesus, Samos, Byzantium and other cities under Rhodian leadership. Rhodes spread its own coinage (with its head of Helios and punning badge of a rose) widely in the east Mediterranean. Phocaea and Mytilene established a monetary union for their electrum. From 404 the Aeginetans were coining again, and on their former weight standard, though with a tortoise replacing the former turtle. Corinthian coins continued to pour out. In the north a variety of important mints opened, and coins from mints in Asia Minor, notably Cnidus and Ephesus, testify to the great prosperity brought by autonomy.

Artistic Development.—In contrast to the deliberate archaism of Athenian types a wide flowering was seen elsewhere. Sometimes this was the result of hybridizing influence, as when Greek artists rendered Scythian motifs at Panticapaeum or Punic ones for Carthage and such of her Sicilian colonies as Segesta and Eryx. Sometimes an artistic tradition was regional, harsh and arresting, as in Crete or, as in Massilia and Emporion in the far west, a weak reflection of finer styles. Generally, however, there was an internationally high standard in coin design. Elis, guardian of the temple of Olympian Zeus and famous for its four-yearly Olympic games, no doubt attempted to impress visitors with superb coinage, the product of a fine local school that has left the initials or part-names of some of its masters. On the coins issued from *c.* 500 to 322 the thunderbolt and eagle of Zeus were shown with Victory in various attitudes; later the heads of Zeus and Hera were nobly represented. In north Greece brilliant artistry characterized the coins of Amphipolis (with a nearly frontal head of Apollo), Acanthus and Chalcidian Olynthus. The coins of Clazomenae and Cnidus in east Greece were also notable for their design.

It was in Italy and Sicily that the finest work appeared. In Italy, Tarentine silver continued its type of Taras on a dolphin. In the middle of the 5th century the agonistic type showing a horseman appeared; the celebrated Tarentine cavalry were thus commemorated down to the middle of the 4th century. About 340 Tarentum issued very beautiful gold coins with a head of Persephone and, on the reverse, the infant Taras appealing to Zeus enthroned. Heraclea, founded in the middle of the 5th century, issued fine staters with a helmeted Athena, and Heracles seated, or strangling or wrestling with a lion. Metapontum introduced a most striking head of its founder, Leucippus. Other mints of the time were at Neapolis, with its types of the siren Parthenope and her father, the man-headed bull Achelous; at Velia, with its head of a nymph and, on the reverse, the eastern type of a lion attacking a bull; at Thurium, with its unusually fine head of Athena and the powerful bull on the reverse; and at Terina, remarkable for its beautiful treatment of the Victory type.

In Sicily, and particularly in Syracuse, the engraver's art reached perfection. The coins of Syracuse showed many varieties of the heads of Arethusa and Persephone, and the chariot of the reverse was found capable of very varied treatment. After the middle of the 5th century, artists began to sign their work, and it is thus possible to prove that other towns engaged engravers from Syracuse. The Syracusan coinage was mainly silver. During the siege by the Athenians, beautiful little gold coins were struck with, reverse, Hercules strangling a lion. With the prosperity following the enemy's defeat, Syracusan art reached its zenith. As the Demareteion commemorated the defeat of the Carthaginians, so the great series of decadrachms perpetuated the memory of the victory of 413 over the Athenians. The agonistic types and the word *athla* on some of them show that they were distributed at the games held to celebrate the victory; their types were widely copied, and their engravers, Cimon and Euaenetus, gained a place among the world's greatest artists.

Among other cities of Sicily there was a notable series from Acragas in the 5th century, with its beautiful double-eagle type, seen most magnificently on the rare and famous decadrachms. Camarina showed fine types of the river god Hipparis and the nymph Camarina on a swan. Himera before its destruction in 408 issued some very interesting types, such as the nymph Himera sacrificing, while Silenus beside her bathes at the thermal spring for which Himera was noted; or Pelops in his chariot, referring to a victory of a Himeran at the Olympic games, which Pelops is said to have founded. Catana used the artist Heracleidas to design a splendid facing head of Apollo. Selinus abandoned its parsley leaf and issued a number of very remarkable types, notably that of Apollo and Artemis in their quadriga and, on the reverse, the local hero sacrificing at an altar, a type that refers to the cessation of the plague as a result of appeals to Apollo as healer.

3. From Alexander the Great to the End of the Roman Republic, *c.* 336–31 B.C.—Alexander introduced a new era in coinage, struck in vast quantities at a variety of mints from Macedon to Babylon with uniform types and weights. After his death the Diadochi and their successors were to reflect the importance of his coinage in their own differentiated issues—Seleucus in Syria, Philip Arrhidaeus in Macedon, Lysimachus in Thrace and Ptolemy in Egypt, where, except for tentative gold coined by Tachos and Nectanebo II between 361 and 343, no coinage had previously been struck. Alexander's influence on the Greek fringe was no less marked. The Arsacid kings of Parthia instituted a Greek style of coinage, and the Bactrian kings did similarly, culminating in the splendid portrait decadrachms of Amyntas *c.* 150 B.C., while even farther to the southeast Indo-Greek kings struck coins, inscribed in both Greek and Prakrit, down to the end of the 2nd century. The flood of coins of Philip II and Alexander, penetrating Europe from the Balkans, resulted in progressive imitations by Celtic peoples westward along the Danube, until these imitations themselves influenced coins in the 1st century B.C. in Gaul and Britain. In the Mediterranean west, by contrast, Greek coinage yielded to the steady growth and advance of Roman power; the issues of Spain and Mauretania late in the period were of hybrid Greco-Roman origin.

The coinage of Alexander established a new style: the coin-portrait became an almost regular feature in a Greek currency that was predominantly regal. The portrait, however, was not at first that of a living monarch. Philip II and Alexander were content with their names on their coins, of which the obverses showed, for Philip, Apollo and Zeus and, for Alexander, Heracles and Athena. Alexander added the title basileus (king) only after his Persian conquest. After his death his deified portrait appeared on the coins of Lysimachus in Thrace and on the early coins of Ptolemy I in Egypt. It was not till 306 that a living king put his own portrait on his coins, when Ptolemy I appeared, still as god, with the aegis of Zeus. Seleucus I similarly put himself on his coins as Dionysus; in time the divine attribute was dropped, and the ruler appeared as a mortal wearing only the royal diadem. In Macedon, Arrhidaeus, Cassander and Antigonus still followed the types of Alexander; and the early coins of Demetrius Poliorcetes (336–283) were without a portrait. Soon, however, his own

portrait appeared, still with the horns that deify him. His successors had only types of deities. Pyrrhus did not appear on any of his extensive coinages, but the last two kings of Macedon, Perseus and Philip V, left very fine portraits. The kings of Pontus, notably Mithradates VI, had a magnificent series of portraits. The kings of Pergamum used the same portrait throughout, that of the founder of the dynasty, Philetairus I, and the Ptolemies in Egypt throughout their long series used only the head and legend of Ptolemy I, except on certain special issues. Among the early Seleucids, Antiochus I was reluctant to drop the portrait of Seleucus I, but the portrait of the reigning monarch became the rule; from farther east came the long series of portraits of the Arsacids and the unparalleled series of Bactrian and Indian kings.

After the vast issues of gold by Philip II, Alexander (under whom its price in relation to silver cheapened to 10:1) and Lysimachus, gold was but rarely struck. Silver was the general metal of coinage; the Attic standard, which Alexander had adopted for his tetradrachms, became the monetary standard of the western world, and there was a great increase in the bronze coinage. Egypt, however, kept to its own standards and to gold.

As the greater part of the Greek world was now ruled by the Diadochi, their various coinages naturally formed the main currencies of commerce. Third-century Athenian coinages were scarce except in bronze. In 229, however, Macedon lost its supremacy over Athens, and friendly relations were established between Athens and Rome. Shortly after 200 the abundant issue of tetradrachms of the "new style" began, which went on for just over a century. The Athena of these coins is not the familiar "archaic" one but a copy of the head of the Parthenos of Phidias, and the owl on the reverse is now perched on a Panathenaic amphora. The ΑΘΕ still remains, but a number of personal names, symbols and letters are added to the reverse, chronicling a long series of magistrates and throwing light on the organization of the Athenian mint and, also possibly, on that of the mines. The other great coin-issuing city, Corinth, went on striking its stater till 229, when, with Corinth's surrender to Antigonus Doson, the long series came to an end.

Rise of Rome.—After the Roman conquest of Greece it is clear from the resumed activity of the mints that the Greek cities were autonomous in one respect at least, for the silver coinage required in Greek territory could be supplied only by Greek mints, the task being beyond the power of Rome at this time. The Thessalians issued silver coins of the type of Zeus and Athena and the legend *Thessalon;* a similar coinage was issued by the Boeotians; Maronea and Thasos issued tetradrachms which became a great commercial currency for trade across the Danube with the barbarians, who imitated them. Macedon itself issued tetradrachms bearing the names of Roman governors. In Asia, after the defeat of Antiochus III at Magnesia, there was an outburst of tetradrachms of Attic weight and local types at towns like Lampsacus, Smyrna and Magnesia. Other cities similarly resumed the issue of Alexander tetradrachms, adding a small symbol to mark the town of issue; *e.g.,* Miletus, Samos, Rhodes. These Alexander types continued down to the middle of the 2nd century, when the Roman province of Asia was set up and cistophori replaced them. These, so called from the Dionysiac chest, which formed the principal type, were first struck at Pergamum after 228 B.C.; the reverse is a bow in a case between two serpents.

In the west the rise of Rome in the 3rd century introduced a new factor into the history of Greek coinage. The first coinage to disappear was that of Etruria—a silver issue curiously always left blank on one side—after a life of two centuries. Rome's early intercourse with the Greek cities of Italy is reflected in the Romano-Campanian coinage. In the south the Italian campaign of Pyrrhus left its mark on various coinages, notably at Tarentum. The towns of Magna Graecia gradually lost their silver coinage under Roman influence, although Greek bronze coins lasted till the 1st century at Paestum.

In Sicily in the 3rd century, Syracusan coinage began to dominate the whole island; the types are mainly imitations of those of the 5th and 4th centuries. The Punic Wars brought the Romans to Sicily, where the Carthaginians had been established since the end of the 5th century and had struck coins of Syracusan and other Sicilian types with Punic legends and later with their own types. Sicily became a Roman province; henceforth only bronze was struck in it, and these local coins continued into the first century, when the last trace of Greek coinage in the west disappeared.

4. Subsidiary Greek Silver Coinages under the Roman Empire.—Although Greek coins under the Roman empire were nearly all of bronze and intended for circulation in and around the cities that issued them, exceptional coinages in silver were allowed by Rome as a continuation, for wider regional use, of important preconquest currencies. The largest of these, running from Augustus down to Diocletian's coinage reform, was minted at Alexandria to supply the needs of Egypt. In addition to silver it included at first tetradrachms of billon (successors to the Ptolemaic tetradrachms); these declined in fineness until by the middle of the 3rd century A.D. they were of mere bronze. Inscriptions were always in Greek. The obverses always bore the emperor's portrait, while the reverses (dated in regnal years by Greek numerals) showed a wide variety of types embracing Hellenistic Roman and Egyptian symbolism, often of peculiar interest and sometimes rendered with skill. Later coins from the Alexandrian mint are commonly found even outside Egypt.

In Syria silver tetradrachms continued to be struck, mainly at Antioch but also at Tyre and some other mints. These gradually became baser in the course of the early 3rd century. Bronze was also struck by the Romans at these mints and frequently bears the letters *S C* (*Senatus consulto*), showing, like similar issues at Rome, imperial initiative exerted through senatorial agency. Of several other local silver coinages the large series of drachms struck at Caesarea in Cappadocia from Tiberius to Commodus is the most important. The usual type was a local one of Mount Argaeus, but common denarial reverses are also found.

A number of vassal states and protectorates continued to issue their own coinages in the precious metals until they became Roman provinces. The only gold coinage of this kind is that of the kings of the Bosporus, who struck coins from the time of Augustus to the beginning of the 4th century, with the Roman emperor's head on one side and the local dynast's on the other. This coinage became gradually debased, passing from gold to electrum, then to silver and billon and ultimately to copper in the 3rd century A.D. In Africa the kings of Mauretania continued to strike their own gold and silver until their realm became a Roman province in A.D. 40.

5. Coinage in Judaea.—Another preimperial series continued under the Roman empire was that of Judaea. Except for rare silver coins of much earlier date, with types of Greek origin but marked with brief Hebrew inscriptions, there were no Judaean issues until *c.* 135 B.C.; the Seleucid coinage of Syria had in the meantime supplied the currency necessary. Antiochus VII, however, had granted to Simon Maccabaeus the right of coinage, which enabled the natural resistance of the Maccabees to Greek polytheism to be satisfied by the representation of specifically Jewish objects—a chalice; a lulab (bundle of twigs) and ethrog (citrus fruit) symbolizing the feast of Tabernacles; a basket of fruit and palm tree. These coins, like those of the rest of the dynasty were of copper. Alexander Jannaeus (103–76 B.C.) was the first of the Maccabaean priestly princes to style himself king on his coins, which bore his name and title in Greek, as well as Hebrew but Pompey's withdrawal of the kingly title was reflected in the coins of John Hyrcanus II. Antigonus Mattathias (40–37 B.C.) the last of the Maccabees, introduced the seven-branched candlestick as a type. Under the Herodian dynasty, from 37 B.C., Greek alone was found on Judaean coins. Herod Philip (4 B.C.–A.D. 34) gravely infringed Jewish convention by showing the effigy of the Roman emperor, but the symbolism of Herod Agrippa I (41–44) was more adroit: in Judaea he avoided the imperial portrait but introduced his own in Caesarea.

From A.D. 66, silver shekels and halves (once dated much earlier) were coined, with some bronze, at "Jerusalem the Holy" to mark the first revolt against Rome: issues of year 5 (A.D. 70–71), a precarious one for the insurgents, are very rare. After the Flavian conquest there were no further Jewish coins until the second revolt

(132–135) of Bar-Cochba, when silver and bronze, frequently overstruck on Roman imperial issues, briefly proclaimed *the redemption of Israel* and *the freedom of Jerusalem*. Jewish coinage ceased with Hadrian's refounding of Jerusalem as Colonia Aelia Capitolina.

6. Greek Bronze Imperial Coinage, to A.D. 268.—Under the Roman republic many Greek cities and districts continued to issue their own bronze coins, and, particularly in Asia, these local Greek coinages went on under the empire down to Gallienus, thus closing the 1,000 years of Greece's numismatic history. These coins have a high historical and archaeological value.

The right of coinage in Greece was sometimes continuous and sometimes intermittently permitted by the emperor or governor. Coins were struck not only by single towns but jointly by alliances of towns (*homonoiai*). The general type is everywhere the same; obverse, a bust and, reverse, a type of local interest. Under the republic the Greek cities usually placed on the obverses of their coins an allegorical bust—that of some local hero or of the people, the senate or the local city goddess. The people (*demos*) in Asia Minor is usually personified as a young male bust; the municipal council (*boule*) and the senate (*sunkletos*) appear as young veiled females. The Tyche of the city appears as a female bust wearing a mural crown. The goddess Roma is found as a helmeted female; *e.g.*, at Smyrna. Under the empire the usual obverse type is the head of the emperor, as on the imperial series proper. There are some notable exceptions. Macedonia, for example, had the head of Alexander the Great. Athens was privileged by Hadrian to use the head of Athena in place of the emperor's.

It is the reverse types of this series of coins that give them their importance. The coins of Athens preserve representations of many statues famous in antiquity that have long since perished, such as the Athena Parthenos of Phidias, the great Athena Promachos on the Acropolis, visible far out at sea, or the Dionysus of Alcamenes. A coin of Elis preserves the Olympian Zeus of Phidias, and one of Lacedaemon the Apollo of Amyclae. Local cults are everywhere illustrated, and incidents in the lives of all the divinities of Greek mythology are common types. Not only are there gods and goddesses but also all kinds of local deities, like river-gods and nymphs. Local celebrities are also recorded; *e.g.*, Homer at several of the various towns that claimed him as a native (notably Smyrna), Anacreon at Teos, Sappho at Eresus in Lesbos, Herodotus at Halicarnassus, Alcaeus at Mytilene, which recorded on its coins a whole series of its famous men, the majority of whom are not otherwise known. Not only are famous Greeks commemorated; the travels of Hadrian in the provinces led to the issue of many specially fine coins, some of which bear the portrait of his favourite Antinous. Reverse types also represent many architectural views (temples especially) of great importance.

Agonistic types are very numerous on account of the great part played by games and festivals in the life of the time. Their celebration is frequently recorded on coins. In conclusion mention may be made of a notable example of the preservation of a local tradition on a Greek imperial coin. On a coin of Septimius at Apameia in Phrygia there appear as reverse type a man and woman in a chest or ark floating on water, with a raven on the top and a dove flying above with a branch in her beak; to remove any doubt about the scene that is represented, the ark is labeled ΝΩ (NO), and the coin is evidence of the local tradition that the ark rested on the mountain behind Apameia.

III. ROMAN COINS

1. The Beginnings.—Although Roman coinage soon diverged from Greek conventions, its origins were similar. Rome, founded in the 8th century B.C., had no true coinage until the 3rd. Roman historians later attributed coinage unhesitatingly to the much earlier regal period: some derived nummus (a coin) from Numa, and Servius Tullius was credited with silver coinage, as well as with bronze stamped with the device of cattle. Roman historical tradition, however, seriously confused the elements of the true picture. Rough, unworked lumps of bronze (*aes rude*) were certainly used as a metal currency from the 6th century, if not much earlier, perhaps in rare conjunction with very small quantities of unworked gold and silver, themselves also passing by weight. Simultaneously standards of value appear to have been expressed in terms of cattle and sheep, as is clear not only from the derivation of *pecunia* ("money") from *pecus* ("cattle" or "sheep") but also from the early assessment of fines in oxen and sheep. From this it was falsely concluded that bronze coins marked with the device of cattle existed from the 6th century. In fact the expression of values in terms of cattle may have lasted, officially, into the 5th century, for it was not until the decemvirs codified the law and drew up the Twelve Tables (451–449 B.C.) that fines were fixed in bronze; and this bronze still consisted of unworked lumps or, at most, rough bars of irregular weight.

During the 4th century B.C. Roman contact with the Greek cities of south Italy slowly increased; these included such prolific mint cities as Nola, Hyria and Naples. The coinages of these cities consisted of silver didrachms, of which Rome presumably made use in any necessary dealings with them. A hint is given, however, of widening Roman monetary interests by two issues (the second of extreme rarity) of bronze token coinage inscribed Ῥωμαίων (with Neapolitan types) and *ROMANO*, respectively. These, though certainly not produced at Rome, may perhaps be regarded as the earliest coins in the name of the Romans, struck at Naples *c.* 325–285 within the terms of their alliance and intended for use in Campania, as distinct from Rome and Latium. It is unlikely, indeed, that a mint in the proper sense existed at Rome before 289, the year to which Pomponius assigned the establishment of *tresviri* who should be *aeris flatores* ("bronze casters"); and this mint (in the temple of Juno Moneta) did not yet produce true coins but *aes signatum*, bronze bars (of about six pounds) lacking a mark of value but bearing on each side a clearly recognizable type (including cattle) and perhaps equivalent in value to a Greek silver didrachm.

These *aes signatum* bars were halfway between *aes rude* and true coinage. In 269 true coinage appeared. It consisted of *aes grave*, large circular cast coins of bronze all bearing marks of value, from the as (weighing one pound) down to its twelfth, the *uncia;* the obverses showed the head of a deity, *e.g.*, Janus on the as, the reverses a ship's prow. These were paralleled (and had perhaps been just preceded) at mints elsewhere by similar cast coins; their types showed not, as at Rome, Latin deities but rather Greek (in the south) or Umbrian and Oscan. At the same time there appeared struck silver didrachms, on the standard of the Greek silver coins of Campania, bearing Greek types, *e.g.*, head of Ares, and horse, but marked *ROMANO* and *ROMA* respectively. Accompanied by small bronze token coins (struck and not cast), these were issued from Campanian mints, and they probably continued down to the Second Punic War, terminating in a new issue of silver coins of Roman style and with Roman types (marked *ROMA*), including Jupiter in a quadriga, from which their name of quadrigati was derived; they were imitated, characteristically in electrum, by the Carthaginians in Capua. The quadrigati were of the weight of the lighter Romano-Campanian didrachms and reflected the rising cost of silver at a time of stress; concurrently the cast bronze coinage of Rome dropped steadily in weight from an as of one pound to one of three ounces or less, becoming increasingly a token coinage as the output of silver coin increased. Financial stress is similarly to be seen in the exceptional issue of gold units and halves, with a Janus head on the obverse corresponding to that of the quadrigati. Toward the end of the Second Punic War the quadrigati were replaced by silver coins of half their weight, with a Victory on the reverse, and hence called victoriati; some of these were certainly struck at Rome, others coming from various and still uncertain mints in south Italy. By *c.* 190 a predominantly silver coinage, Latin-inscribed, was in production at Rome and other mints selected by Rome; it was accompanied by bronze coinage so greatly reduced in standard and thus size that it could at last be struck instead of being cast. The sequence in which the metals had been either cast or struck was reflected in the full title of the three mint officials, the *tresviri aere argento auro flando feriundo*—for the casting and the striking of bronze, silver and gold.

2. Introduction of the Denarius.—Adjustment of the previously fluctuating relationship between bronze and silver was first secured by the issue of the silver denarius (marked *X*, *i.e.*, 10 bronze asses), together with fractional coins, also of silver, marked *V*, *i.e.*, 5, and *IIS*, *i.e.*, $2\frac{1}{2}$ asses (or a sesterce or sestertius). The evidence of Plautus, combined with that of coin hoards and other factors, suggests a date for the new coinage *c.* 190 B.C., though in fact the true date may be about 20 years earlier. The denarii were lighter than the quadrigati; their types were a Roma head on the obverse, with the Dioscuri and *ROMA* on the reverse; and they were perhaps struck at a number of mints (including Rome), like the issues before 190. The victoriati, again lighter (their weight standard had come from Illyria), were issued until *c.* 150 B.C., being perhaps intended for principal circulation outside Italy. The denarius, however, which came to be issued in quantity, quickly established itself as the major currency of the time in the central and western Mediterranean. In her eastward expansion Rome learned to make use of local currencies—gold staters of Macedon and silver tetradrachms of Athens or Asia. Rome was also prepared to employ Macedonian gold in the west, as was shown by the release to western markets of large quantities of gold staters after *c.* 150 B.C. In the 2nd century B.C., Roman coinage in gold was very rarely undertaken. Coinage in bronze, on the other hand, was continued, but further variation in silver/bronze values was seen in two further developments. The as dropped in weight to that of an uncia and then less, becoming a token currency; together with its fractions, it was now always struck and not cast. Secondly, the value of the denarius in terms of bronze was altered, being revalued *c.* 133 at 16 instead of 10 asses; the silver quinarius (now of 8 asses and with the types of the victoriatus) became rare; and the silver sesterce (now equal to 4 asses) virtually disappeared. After *c.* 80 B.C. the striking of bronze was discontinued until the time of Caesar.

These developments mirrored the economic difficulties of the day. Reduction of the weight of the as from 1 oz. to $\frac{1}{2}$ oz. in 89 B.C. was accompanied temporarily by debasement of the denarius, resulting in the issue of denarii with serrated edges, intended to show that they were not plated.

3. Control and Content of the Coinage.—The coinage was controlled by the senate, acting for the sovereign people; and the conduct of the mint of Rome, and also of Italian branch mints elsewhere, was in the hands of a board of junior magistrates, the *tresviri* already mentioned. From about the middle of the 2nd century each of the three *tresviri* normally issued coins bearing his own name, and on special occasions these were supplemented by issues of quaestors, curule aediles, prefects or praetors; these were distinguished by special inscriptions like *ex s*(*enatus*) *c*(*consulto*) and *ex a*(*rgento*) *p*(*ublico*). The function of all these officials was to put out a given quantity of coinage of given purity.

The moneyers' names at first were shown as simple monograms, seen on denarii of early date bearing the types, standard for some four decades, of *ROMA* head on obverse, with the Dioscuri and *ROMA* on reverse. The Dioscuri reverse was followed by Diana or Victory in a biga (two-horse chariot), and these again by figures of Jupiter, Juno or Apollo in a quadriga, coinciding with the moneyers' names in fuller form. In the mid-2nd century B.C., however, newer tendencies appeared, as when Sextus Pompeius Fostlus paired the Roma obverse with a reverse showing his traditional ancestor Faustulus in the act of discovering the wolf and twins; the reference was to the greatness of Rome, but it was to be seen through the lineage of a moneyer. Later republican denarii gave keen expression to party politics, as when corn ears recorded *c.* 100 the purchase of grain by the quaestors Piso and Caepio, or the head of Ceres with ploughing oxen proclaimed the program of the Marians, or Sextus Nonius Sufenas advertised the games that, as praetor and a supporter of Sulla, he had staged for the Roman populace.

It was in the provinces, however, that the republican coinage took the decisive steps toward its finally imperial character. Campaigning generals began, in the 1st century B.C., to operate (by virtue of their imperium) mints for paying their troops in the field. In Italy mint policy had usually looked beyond personal politics to the state. But the military coinages of the *imperatores* equated the state with the personalities of the generals themselves. Such were the aurei and denarii struck from eastern mints *c.* 82–81 by Sulla, with, obverse, *L. SVLLA* and head of Venus (his family patroness) and, reverse, *IMPER*(*ator*) *ITERVM*, priestly jug between trophies. Pompey issued comparable aurei *c.* 61 (also in the east). From these precedents the earlier coinage of Julius Caesar followed naturally in the late 50s and early 40s, with obverse, *CAESAR*, elephant (the family badge) and, reverse, priestly symbols, or, obverse, head of Venus (his traditional ancestress) and, reverse, *CAESAR*, Gaulish trophy and captives. Such coinages still avoided the portraiture of a living man, the only examples of which hitherto had been on provincially struck coins; *e.g.*, Flamininus' features on the famous gold (now very rare) that he coined in Greece in the 2nd century B.C.

4. Caesar and After.—In the last year of his life Caesar developed personal control of the coinage to a point at which it lay ready to hand for Augustus to use, a few years later, as a fully imperial instrument. Already from 46 B.C. coinage in gold had been instituted in Rome by Caesar's lieutenant Hirtius. Caesar's seizure of the treasury, and his expansion of the annual board of moneyers from three to four members, indicated his intention to deal absolutely with the coinage. In 44, denarii were issued in considerable quantity by his *quattuorviri*, bearing the portrait of Caesar on the obverse, with such inscriptions as *DICT*(*ator*) *QVART*(*o*) or *DICT*(*ator*) *PERPETVO*, and Venus Victrix or other semipersonal reverse types. For the token coinage a new alloy was now first struck—yellow orichalcum or brass, a copper-zinc alloy heated with calamine. Caesar may have enjoyed a monopoly of zinc from mines in Cisalpine Gaul.

From 44 to 31, bronze coinages were struck at various non-Italian mints, notably in or around Sicily, by officials attached to the cause of one or other of the members of the second triumvirate—Antony, Octavian and Lepidus. But the principal issues of these years were of gold and silver. The mint of Rome continued its regular series until *c.* 37 and then ceased. Antony's coinage emanated at first from Gaul, then increasingly from eastern mints, including his cistophori and denarii (some showing his head conjoined with Cleopatra's) struck in Asia: his vast issue of often base denarii showing warships and military standards shortly before Actium, was eastern. Octavian coined mainly in Gaul, Italy and Africa. The piratical movement of Sextus Pompey was reflected in the activity of a mint or mints in Sicily.

It was characteristic of most of the gold and silver after 44 that it showed portraits of the rival statesmen on the obverses, with reverses that alluded to their achievements or policies. This was true even of the "liberators" who murdered Caesar, for a famous eastern issue in the name of Brutus showed his portrait with *BRVT*(*us*) *IMP*(*erator*) on the obverse, with reverse *EID*(*ibus*) *MAR*(*tiis*)—the fatal Ides of March—and daggers flanking a cap of liberty. By the close of the Roman republic three factors had entirely transformed the originally simple idiom of the early denarial coinage: gold was freely struck in addition to silver; the types of both were personal to military leaders and included living portraiture; coinage could be produced, through exercise of imperium, elsewhere than at Rome. All these were fundamental in the imperial coinage from Augustus onward.

Early Imperial Mint Policy.—Augustus (27 B.C.–A.D. 14) based the coinage on the aureus of $\frac{1}{42}$ of a pound of gold, equivalent to 25 denarii, each of $\frac{1}{84}$ of a pound of silver, the metals being struck almost pure. The denarius was valued at 16 asses. Base-metal coinage consisted of brass sesterces and dupondii (equal to four and two asses), with copper asses, halves and quarters. The as was the commonest coin. Nero in A.D. 64 lightened aureus and denarius to $\frac{1}{45}$ and $\frac{1}{96}$, respectively, but debasement of silver subsequently took place. Under Septimius Severus it reached 40%, and Caracalla issued a debased double denarius of the weight of only $1\frac{1}{2}$ denarii. Gallienus' copper double denarius, only washed with silvery coating, marked a monetary breakdown only partially cured when Diocletian and Constantine again made good the firm basis for supplementary pure silver and abundant copper coinage.

Augustus' earliest gold and silver were coined chiefly in the east, *e.g.*, at Ephesus and Pergamum, and more briefly at Emerita in Spain. Bronze also was mainly eastern, though some was struck at Nemausus (Nîmes). The Rome mint was reopened *c.* 23 B.C. for gold and silver and remained open for this purpose until *c.* 12 B.C.; its bronze continued irregularly. From 12 B.C., Lugdunum (Lyons), with other mints of uncertain identity, undertook the main western coinages in gold, silver and bronze; after interruption Lugdunum was again a major bronze mint in Nero's last years and under the Flavians; it was active also in the 3rd century, when Siscia, Mediolanum and Viminacium were coining as well. After 64 Rome was once more the chief mint for all metals. Official mintages were supplemented by a mass of regional or local coinages, from Roman colonies, from towns that coined by special permission, from preimperial mints continuing in the east, and from Alexandria, while official coinages from eastern mints, *e.g.*, Caesarea in Cappadocia and Syrian Antioch, provided necessary currency for Roman frontier forces there.

The bronze of Rome was marked *S(enatus) C(onsulto)* and continued to bear the names of the *tresviri monetales* (now reduced to their traditional number) until 4 B.C. But *S C* also appeared on bronze from Lyons and Antioch in imperial provinces, showing that whatever nominal senatorial rights of coinage still lingered on—the *tresviri* are known until the 3rd century—the emperor wielded effective control over all metals everywhere. This was logical, since his economic powers were equally comprehensive. In fact the old senatorial mint was transferred from the temple of Juno Moneta on the Capitoline and merged, probably after the fire of 64, with an imperial establishment for gold and silver in the Third Region. Henceforth it worked in sections—six were normal later—each controlled immediately by an imperial procurator and staffed by slaves or freedmen. Imperial supremacy of mintage as a whole is implicit in the nearly constant appearance, on gold, silver and bronze alike, of the portrait and some elements of title of all emperors from Augustus onward; *e.g.*, *Imp(erator)*, *Caesar*, *Augustus*, *Tribunicia Potestate*.

Portraits and Types.—Caesar's use of his own portrait upon coinage set a precedent; although under Augustus and Tiberius token denominations occasionally lacked the imperial portrait, it was thereafter an essential element of virtually every gold, silver and bronze coin of the official mints, as also of nearly all provincial and local coins. Emphasis on the personality of the emperor (extended sometimes to empresses, sons or deceased members of the imperial house) was a powerful instrument in a coinage, which, bearing also the imperial titles in brief form, reached throughout a vast empire; the coin portrait enjoyed an almost sacred respect under a political system that normally required or encouraged the worship of the emperor's Genius. The great series of imperial portraits, from Augustus down to Romulus in A.D. 476, is artistically outstanding. Many of the finest appeared on the large brass sesterces down to the 3rd century and on the even larger bronze medallions produced for presentation; but particular care was taken over the portraits for gold, which, being softer, showed a beautiful and highly sensitive impression. Nothing is known of the portrait artists, though it is likely that they were often from the Greek east.

Imperial reverse types, if artistically less remarkable, are uniquely important for the unparalleled fullness of the historical commentary—religious, political and social—that they supply. The major mints provided annual evidence of imperial interests: victories in war; frontier defense, *e.g.*, *Rex Parthis datus* of Trajan; a well-earned peace, *e.g.*, the *Pace terra marique parta Ianum clusit* of Nero; the birth of an heir or alternative provision for the succession; public shows; acts of social reform or public relief, *e.g.*, *Civitatibus Asiae restitutis*; imperial journeys, *e.g.*, *Adventus Augusti*; and religious or other anniversaries, *e.g.*, the *Felix temporum reparatio* on Rome's 1,100th birthday. Their interpretation demands care, since, being selected by imperial officials, their tenor can conflict with the attitude of anti-imperial historians. But they show the efforts made by emperors, as the omnipotent semireligious heads of a huge and heterogeneous empire, to conciliate and mold opinion. They contributed powerfully to the growing conception of the *Aeternitas Imperii Romani*, seen no less in the special types of eagle (the soul flown heavenward) or funeral pyre or temple in honour of "good" emperors consecrated as *divi* than in the annual record of military victory, economic security and provincial peace, and implicit in the regularity of imperial succession. The normal colour given to this imperial program was religious, for the coinage types commonly embraced such characteristically Roman concepts as Aequitas, Fides, Concordia, etc.—social virtues operating in the guise of minor deities.

5. The Fourth Century and After.—Diocletian's institution of the tetrarchy, by which the empire was divided administratively between two Augusti and two Caesars, brought fundamental changes in social and economic policy; the instability of prices called for complete renewal of the monetary system. His coinage reforms took place in stages from *c.* 286 to *c.* 296. First, new aurei (issued in some quantity) were struck at 60 to the pound of gold. Then, *c.* 293–294, new silver coins, of good purity, were struck at the revised Neronian weight of 96 to the pound of silver. Finally, *c.* 294–296, new copper coins appeared, which (perhaps pieces of 5 denarii) were larger and intrinsically more valuable than the small debased double denarii of previous reigns. The contemporary names of these silver and copper pieces are not known. This reformed coinage was struck at a variety of mints from London to Alexandria, most of which coined in all three metals, though some produced only silver and copper, or even copper alone. Types were closely controlled in the silver and copper coinage; in the latter the almost universal type was for some years that of the Genius "Populi Romani." The obverse bore the portrait of one or other of the tetrarchs, each of whom coined with portraits of all four.

The breakdown of the tetrarchy after 306 weakened the new system. Copper was quickly and steadily lightened, and silver came to be struck only very sparingly. Gold, however, for so long the basis of imperial coinage, continued in good supply; and though Constantine's solidus showed a reduced weight-standard (from $\frac{1}{60}$ to $\frac{1}{72}$ of a pound of gold—setting the standard for the famous bezant of the Byzantine empire), there was no shortage of gold throughout the rest of the 4th century. In time silver coinage increased, especially after *c.* 350, when the miliarense ($\frac{1}{1000}$ of a gold pound) and smaller denominations appeared in some quantity. By the end of the 4th century the size of copper coins had dropped very sharply, and in the 5th, until the western empire collapsed in A.D. 476, the western coinage consisted finally of gold with a little silver, struck mainly from the mints of Ravenna and Rome.

From 312, when Constantine took Rome, coin-types at all mints began to show new tendencies. The imperial portrait, often armoured and warlike, was still the dominant feature. Reverses displayed complementary themes represented in a way unknown to the 3rd century or before—the glory of the army, vows for continued imperial rule, the constant struggle against barbarian pressure on the frontiers. The old variety of pagan gods—Jupiter excepted—mainly disappeared, though Sol, popular from Aurelian onward, was used specially by Constantine. Christian emblems did little to take their place, though the Christian monogram, the Greek letters chi and rho superimposed, sometimes on a standard, began to appear with Constantine and was combined with the alpha and omega under Constantius II and Magnentius. On the whole, however, there was an unavowed truce between Christianity and paganism, only occasionally broken, as when Julian deliberately revived a range of pagan, and especially Egyptian, types; the full development of the Christian tradition in coinage was reserved for Byzantium.

IV. COINAGE IN WESTERN EUROPE, AFRICA AND THE BYZANTINE EMPIRE FROM THE 5TH TO THE 10TH CENTURY

The fall of Roman power in the west left the gold currency of the Byzantine empire undisturbed; it was to become the most dominant single influence in European coinage for 1,000 years, competing at first with the gold of the Arab caliphates and lat-

terly with that of the great Italian commercial republics as well. Byzantine coinage, in its continuity, contrasted strongly with the often erratic monetary systems from the 5th to the 7th centuries in western Europe, where Germanic invaders inherited the apparatus, money included, of the Roman empire. In general, the main features of late Roman coinage were taken over. Emphasis on gold continued, with silver and (where it was struck at all) some bronze; gold chiefly served for the triens ($\frac{1}{3}$ of the Constantinian solidus). The types of the gold coins for some time reflected Byzantine prestige, for they showed on the obverse the "portrait" (purely formalized) and titles of the reigning Byzantine emperor, toward whom widespread respect was paid even when western kings began to add their personal monograms to the normal Victory reverses. Imperial prerogative, so powerful an influence upon western gold, had less effect on silver, the types of which in the west became more flexible; in bronze, where obvious efforts were sometimes made to link with traditional Roman design, flexibility was greater still. In technique these coinages varied widely: that of Italy was not without elegance; that of Spain developed an elaborately stylized balance, depending largely on its bold letter-forms; the highly abstracted figures of Gallic coins have found great favor among 20th-century artists, while those of Africa and England were in general considered artistically inferior. The weights of gold coinages were kept at a reasonably steady level, though fineness ultimately declined with the economic decline of the issuing kingdoms themselves.

1. Post-Roman Coinage of the West.—In Italy the Herulian Odoacer (476–493) had coined in silver and bronze at Ravenna after setting up a Teutonic kingdom. The Ostrogothic coinage that followed, from Theodoric (493–526) onward, consisted of gold, mainly imitating current Byzantine issues and with the imperial portrait (Theodoric's fine portrait on a unique triple-solidus is wholly exceptional). Silver and bronze were supplementary. The normal mints were Ravenna, Milan and Rome, the last of which, emphasizing the senate's lingering role, employed essentially Roman types for its bronze, though its portraits, *e.g.*, of Theodahad, are substantially Gothic conceptions. Silver usually bore a king's monogram, though the name (in the form *Dn . . . Rex*) might also appear in full. The Lombards of Italy (568–774) had no distinctive coinage of their own until the gold struck in the name of Grimoald, duke of Beneventum (662–671), which was followed by gold and silver from a number of mints elsewhere. In Africa the Vandal kings Gunthamund (484–496) and Hilderic (523–531) issued silver and bronze coinage, respectively, inscribed with their names; the types and denominations looked to imperial models and, in the case of the bronze, to those of Carthage especially. Vandal gold was perhaps struck by Gaiseric (428–477) or Hunneric (477–484), in the Byzantine emperor's name, but in the absence of any royal monogram it cannot easily be attributed. The chief Spanish coinage was that of the Visigoths, who controlled south Gaul also and—after Leovigild (568–586)—Suevia (modern Galicia), with its rich gold mines; hence the fact that of 79 Visigothic mints a high proportion was concentrated in northwest Spain. Visigothic gold coinage was produced in quantity down to the early 8th century and consisted almost entirely of thirds, at first imitating Byzantine models, and bearing kings' names with such titles as *D*(*ominus*) *N*(*oster*), *Pius*, *Iustus* and *Rex*. The most prolific mints were Mérida, Toledo, Seville, Tarragona and Cordoba; coinage continued until the Arab invasion of Spain.

In Gaul the Burgundians struck their own imitative gold thirds, first, under Gundobad (473–516), inscribed with a recognizable royal monogram, though not yet displacing the imperial name and portrait. The largest of the Gaulish coinages, however, was that of the Merovingian Franks, beginning with Clovis (481–511). The gold consisted mainly of thirds, at first with some subsidiary silver and copper, inscribed by Theodoric of Austrasia (511–534) and Childebert I of Paris (511–558) with their own names. As elsewhere, the types of the gold borrowed steadily from the imperial series, either the former Roman or the current Byzantine. Reverses showed a Victory, though the theme of the "cross on steps" of Tiberius II (578–582) gradually displaced it, beginning in the south. Obverses generally showed a profile bust derived however remotely, from imperial models; in time there was some borrowing of frontal busts under Visigothic influence. A profound break with tradition came when Theodebert I (534–548, substituted his own name on his gold for that of the Byzantine emperor —a change that in turn was to influence Visigothic gold. The right of striking gold had meanwhile been widely extended, for in addition to coins declaring their royal origin *in palatio* (principally at Paris) there were others, which became much more profuse, coined by cities, towns and ecclesiastical foundations. Presumably such mints operated by royal permission; their numbers were great—nearly 500 in all—and they were distributed over an area including not only what is now France but also the Low Countries, the Rhineland and Switzerland. The types of Merovingian gold coins diverged increasingly from imperial models: nearly all of them were inscribed on the obverse with the name of the issuing authority, most often municipal, and on the reverse with the name of the moneyer, who, as in the case of Eligius (St. Eloi of France), might be well known both as a cleric and as a goldsmith. As the Merovingian dynasty drew to a close in the 8th century, gold coinage became poorer in quality, and it gave way to the small silver denarius, of about 1.2 g., struck in quantity. This change heralded the Carolingian revival of the denarius.

Coinage supply to England was interrupted when the mints of Roman Gaul were closed *c.* 395, and scarcely any gold or silver coin entered the former country during *c.* 450–550. Subsequent penetration of Merovingian gold encouraged a brief Anglo-Saxon coinage of gold thirds (*see* below).

2. Coinage in the Byzantine Empire.—Inspiring many features of these transient coinages, but outliving them all, stood the currency of the Byzantine empire. It was based on the gold solidus ($\frac{1}{72}$ of a pound) of Constantine—the bezant of 4.5 g. (about 70 gr.) maximum, which dominated so much of European trade down to the 13th century. Down to the 10th century halves and thirds were also used. This gold was proverbial for its purity until the 10th century. The fundamentally religious nature of the empire was fully reflected in the coinage: throughout ten centuries there was scarcely a single issue that did not look direct to the Christian faith, since apart from reverse types and legends, which were purely religious, the obverses showed the emperors as specifically Christian rulers by the use of adjuncts or appropriate inscriptions.

Byzantine coinage began effectively with the reign of Anastasius (491–518). Thenceforth it consisted, in addition to gold, of silver and bronze. Silver, always rather rare, consisted of the small siliqua or keration, followed by the larger miliaresion and the still larger hexagram. Bronze was in most periods very commonly struck. Its appearance and tariffing were reformed by Anastasius, who issued large pieces marked *M*, *K*, *I* and *E* (equal to 40, 20, 10 and 5 nummi); other multiples were found either later or locally, as *IB* (equal to 12 nummi) at Alexandria. Such marks of value continued until Basil I (867–886), after whom the recognition of specific bronze denominations becomes difficult. Constantinople itself was the main mint in all three metals, which were coined also at Carthage and Ravenna. Thessalonica, Nicomedia, Cyzicus, Antioch and Alexandria struck bronze only; at one time or another Rome struck gold and bronze, while Syracuse and Catania also contributed. The technique of gold and silver minting was generally high. That of bronze, which had a token character, was coarse, and the practice of overstriking former coins was often employed.

Types and Legends of Byzantine Coins.—The types, though they suggest considerable uniformity, in fact display steady development and, occasionally, abrupt change. For gold the earliest obverses were diademed profile busts or helmeted facing busts, both common on previous coins of eastern and western empires. The facing bust showed the emperor in military panoply with cross in his hand or on his helmet, and if the cross was lacking on the obverse it appeared on the reverse. With Justin I and Justinian I (527), the seated figures of the emperors were shown side by side. Thereafter the facing head became more common; from the time of Phocas (602–610) it was increasingly formalized

a process that reached its climax in the 8th century, with ceremonial vestments taking the place of earlier military robes. Under Heraclius (610–641) the habit began of showing the bust or standing figure of the emperor with that of one or more of his sons; and, with figure-types now more common, it was possible to show emperor and empress together, or even, as with John I Zimisces (969–976), the emperor being crowned by the Virgin, with the hand of God above. The reverses of the gold coins at first emphasized the Victory (doubtless regarded as an angel) of previous issues. Tiberius II (578–582) introduced the cross potent on steps, a type destined to play a long and important part. Standing figures of members of the imperial family came later. Justinian II (685–711) was the first to use the haloed bust of Christ, of both a youthful and an older aspect: Christ had previously been shown only on a coin of *c.* 450, in the act of marrying Pulcheria to Marcian. The iconoclasm of Leo III (717–741) and his successors banished such divine representations in favour either of the cross on steps or of imperial figures on the reverses, but with Michael III (842–867) the bust of Christ returned. From Basil I the throned, full-length figure of Christ predominated.

The obverses of the silver coins, beginning with profile busts, thereafter included seated figures, facing busts and purely epigraphic designs incorporating imperial names and titles. The introduction of the larger hexagram by Heraclius in 615 allowed fuller scope for later designers, whose reverses often consisted of a cross on steps or a bust of Christ surrounded by legends, such as *Deus Adjuta Romanis* or *I H S Christus Rex Regnantium;* from the 10th century the cross bore a central portrait-medallion of the emperor himself.

In bronze coinage there was at first less flexibility. The earliest types were, obverse, a profile bust and, reverse, cross and mark of value. Under Justinian I (527–565) the facing bust prevailed, and in his 12th year he introduced the dating of his bronze coins on the reverse, in the form *Anno XII;* the inclusion of a regnal date was thereafter normal on bronze until Constans II (641–668). From the time of Justin II (565–578) the obverses showed two or more standing imperial figures, and sometimes the reverses too, combined (until Basil I) with the mark of value. Not until the 10th century was there any abrupt change. Thenceforth the reverses were taken up wholly by three or four lines of inscription; and the anonymous bronze coins of John Zimisces combined such a reverse, reading *Iesus Christus Basileu(s) Basile(on)*, with an altogether new type of obverse showing the facing bust of Christ designated *Emmanuel.*

The orthography of Byzantine coin-legends became remarkably complex as the Latin and Greek alphabets were increasingly mingled and when individual letters took on new or specialized forms and words were severely abbreviated. At first the inscriptions were purely in Latin, the emperor's names and titles being in the conventional form *D(ominus) N(oster)—P(ius) F(elix) Aug(ustus).* Even before Anastasius, however, *Perpetuus* had been a variant for *P.F.*, and, abbreviated in the form *PP*, it finally prevailed. In the 7th century, Greek letters were more commonly mixed with the Latin, in such legends as that of Justinian II when he styled himself *Servus Christi;* and in the later 8th the general shift to Greek from Latin conceptions was plain in the emperor's new title of *βασιλεύς*, that of *δεσπότης* (at first reserved for the heir-apparent) also coming in later as an imperial equivalent, with the variant *δέσποινα* for an empress regnant. The title *αὐτοκράτωρ* was introduced in the 10th century, which also saw the beginning of comparatively long votive inscriptions, as *Lord, help thy servant.* Metrical inscriptions (a practice commoner in Asia than in Europe) began in the 10th century; though they never became common, they were often elaborate.

Economic Role of Byzantine Coins.—Byzantine gold coinage, until its debasement from the 10th century, was immensely important in the economic life of the Levant and western Mediterranean. The total output of gold was immense, and its influence can be judged partly from the distribution of the coins themselves and partly by the typological influence exerted by the Byzantine upon other coinages, from the first Arab-Sasanian gold of the east to that of Italy and Gaul in the west. In the 5th and 6th centuries Byzantine solidi accumulated in the Baltic area, doubtless in payment for furs; and, in the 6th and 7th, solidi of a slightly lighter weight (*solidi mancussi*—probable source of the term mancus) were hoarded over a very wide area, including France, the Low Countries, Scandinavia, Germany, the Balkans, Russia, the Levant and north Africa. In these last two regions Byzantine gold competed from the 7th century with the increasing output of Arab gold dinars.

3. Charlemagne and the Carolingian Coinages.—While the bezant and dinar maintained gold currency along the Mediterranean, northern Europe from the 8th century suffered a shortage of gold and turned its almost exclusive attention to silver, inherently more convenient as a unit of exchange. A previous Merovingian tendency to introduce silver alongside gold was carried much farther when the Carolingian ruler Pepin the Short (752–768) replaced gold by silver, introducing the denier, which was to be the basis of all medieval coinage in the north. His new coin settled at first to a weight of 1.28 g. ($19\frac{3}{4}$ gr.) and was wider and thinner than previous silver pieces. The normal types were simple—obverse *R P* (for *Rex Pepinus*), reverse *R F* (for *Rex Francorum*).

Charlemagne (768–814) reorganized northern currency in a way that affected it permanently. Coining at first simply as *Carolus R F*, he defeated the Lombards in 774 and entered Rome, becoming king of Lombardy as well. His deniers were later made wider and still heavier (about 25 gr.), and he introduced the smaller and subsidiary obol or half denier. The main types of his deniers were threefold: the monogram of his Latinized name Carolus; a temple (sometimes a gateway); and more rarely a portrait. Monogram deniers were coined in France, Germany, north Italy and northeast Spain; temple deniers were also widely struck, often inscribed *XRISTIANA RELIGIO*, though this legend was sometimes replaced by the name of a major French mint-city. On Christmas day 800 Pope Leo III crowned Charlemagne as Roman emperor, and thenceforth his deniers, either with the temple type and "Christian" legend or with a mint-name alone, styled him *Kar(o)lus Imp. Aug.*, sometimes adding *Rex F(rancorum) et L(angobardorum)*. His mints lay mainly in France, the Rhineland and the Low Countries; those in north Italy and northeast Spain were few.

Louis le Débonnaire (814–840) continued his father's monetary system with little essential change. But the infringement of his mints emphasized the economic importance of northern ports, especially the Frisian Duurstede, from the neighbourhood of which (including perhaps Hamburg) emanated large numbers of more or less skilful copies of the gold sous (or, occasionally, of the half-sous) that Louis struck. These portrait coins originally were designed presumably for presentation to the Holy See, since the reverse bore the inscription *MVNVS DIVINVM* around a cross. They were struck sparingly, and no Carolingian gold thereafter appeared. Charlemagne's pattern of coinage, sometimes varied, was extended to Lotharingia, with such powerful mints as Cologne, Metz, Trier and Strasbourg. From the time of Louis II and III (877–882) the Carolingian currency pattern weakened, and feudal coinages made their first appearances. Louis IV d'Outremer granted coinage-rights to the archbishop of Reims as early as 850, and the system was swiftly developed in the 10th century, concessions being made to a large number of ecclesiastical foundations and even in a few cases to lay lords as well. In Spain, Carolingian mints were established only in the extreme northeast, at Barcelona, Ampurias and Gerona. The kingdom of Aquitaine, under Charlemagne, was reserved to the Frankish king's son, and its coins were modeled strictly on the Carolingian pattern. Northern Italy was an integral part of the territories controlled by the earlier Carolingians, but from the middle of the 9th century changes began to show: the deniers of Pavia and Milan, though retaining essentially Carolingian types, became much broader and thinner, with wide rims like those of the later German bracteates. Venice, a republic from the late 7th century, ruled by a doge under Byzantine protection, did not coin until the 9th, when it struck deniers for the Carolingians; but after Lothair I it omitted mention of the imperial name. At Rome papal coinage began with Adrian I (772–795),

Byzantine in style and types, but after Charlemagne's visit in 774 all deniers (except during an imperial interregnum) were struck jointly with the pope's monogram and the emperor's name, down to 904; thenceforth the papal name appeared in full and alone. The principalities of Beneventum and Salerno and the duchies of Naples and Amalfi fell within the Byzantine-Arab orbit, and their gold, silver and bronze showed these besides Carolingian influences; bronze coins in particular followed Byzantine models, while the gold tari of Salerno were curious copies of Arab dinars. In central Europe, Carolingian coinage was not reflected east of the Rhineland, but in the north the imitation of Carolingian money in or around Duurstede bred more distantly derivative issues elsewhere, possibly even in Scandinavia; these were in effect silver deniers, but their types, with their emphasis on ships and animal designs, show them to belong to the Nordic, as opposed to the Teutonic, stream of monetary design.

V. THE LATER MEDIEVAL AND MODERN COINAGES OF EUROPE

The change of power from Frankish to German emperors in the 10th century saw the silver denier extended into central and northern Europe; it was issued from a great variety of mints, imperial, regal, autonomous and, above all, feudal. In the east the decay of the Byzantine empire was reflected in the debasement of its gold coinage to electrum; after the temporary fall of Constantinople to western crusaders in 1204, Byzantine tradition was carried on in the silver coinages of the derivative empires of Trebizond, Nicaea and elsewhere. The revival of gold coinage in Italy in the 13th and 14th centuries, promptly copied elsewhere, led to the need for a silver denomination larger than the denier, and the grosso and its equivalents soon spread widely. From the 14th century the outward appearance of coinage was fundamentally changed from its former Gothic stiffness: the Italian Renaissance pointed the way to naturalism in portraiture and to greater fluency of ornament. In the 15th century the first Italian experiments were made with mechanical methods of coining (*see* below), and by the 16th the new techniques were being generally adopted. The effects were important: the traditionally privileged nonregal mints were incapable of competing with the mechanical power needed to cope with the intensive coinage not only of the large gold denominations resulting from the influx of Spanish-American treasure after 1493 but also with the equally large silver thalers or dollars, starting with those of the German Joachimsthal mines, which were in turn required. Multiplication of gold and silver coinages, and their larger denominational values, emphasized the need for token coinages, which were steadily produced from the 17th century. England was effectively on the gold standard from the end of the 18th century, together with Portugal, but it was not until the second half of the 19th that European countries in general followed suit. Paper currencies of this period were fully redeemable in gold coin, but the gold standard was abandoned in World War I; since then paper has been redeemable only in "silver," which in most countries since 1918 has consisted increasingly of nickel or other base-metal alloys.

The coin-types of the later medieval period started with the simple devices, often crudely executed, which the Carolingian coinages made widely familiar—a monogram; legends (whether arranged in circular or linear form); a cross; a "temple" or church of elementary shape; or a more or less formal portrait. Portraiture, schematically stiff on later Byzantine money, was revived with striking realism most notably in Renaissance Italy and thereafter flourished. Reverses revealed feudal influence in shields of arms and civic emblems (either inanimate badges or devices with animal or human figures); after Renaissance modes prevailed, these were retained in adapted forms. These developments set the general pattern of modern coinage, usually with an obverse portrait and some form of national badge or arms on the reverse. From *c.* 1800 onward this pattern has been standardized to a large degree.

1. Portugal.—Coinage began, after the expulsion of the Moors, with Afonso I (1128–85), whose gold maravedis, copied from the gold of the Almoravids, retained certain Arab features in design. Some base silver was also struck. Rights of coinage were, from the start, reserved to the kings, almost without exception. Pedro I (1357–67) reformed the coinage on the basis of the gold d[illegible] of about 4.9 g., with types copied from those of contemporary France: obverse, king enthroned; reverse, ornamented cross. There was a similarly imitative silver gros tournois. Pedro's successors developed his system. Copper was struck from the 15th century. From the 16th to the 18th centuries gold was coined in quantity and in denominations of handsome size down to the half-escudo. In the 19th century the basic gold denomination was the crown. In the 20th century token denominations (in terms of centavos) have prevailed in various alloys, though silver was introduced in 1954 for the ten-escudo piece and for certain purely commemorative issues.

2. Spain.—As in Portugal, the coinage struck after the expulsion of the Moors was almost without exception regal. That of Navarre started under Sancho III (1000–35) with deniers of Carolingian influence. The series of Castile and León began with similar pieces under Alfonso VI (1065–1109), and that of Aragon under Sancho Ramirez I (1063–94). Among the earliest gold, struck from the mid-12th century, was that of Alfonso VIII of Castile (1158–1214), copying an Arab gold dinar but with Christian instead of Islamic professions in its Arabic script. Gold portrait doblas appeared under Sancho IV of Castile and León in the 13th century, and the portraiture under Pedro I in the 14th was of high quality. Gold coinage multiplied in the 15th century, with Henry IV coining huge pieces up to 230 g. of superb Gothic style; silver and billon were also in good supply. The union of the crowns of Castile and Aragon in 1479, and subsequently the influx of American precious metals, resulted in an abundant coinage in gold (the excelente and its multiples) and silver (the real and its multiples) —the silver piece of eight being the famous Spanish dollar. This last denomination enjoyed enormously wide currency, and its types (obverse, royal portrait; reverse, pillars of Hercules with *PLUS VLTRA* on scroll) were universally known, especially in the 18th century, and continued into the 19th and 20th centuries, being used by Alfonso XIII and, with appropriate changes, by Gen. Francisco Franco.

3. France.—The dynasty of Hugh Capet (987–996) made no immediate change in the previous Carolingian coinage system: deniers and their halves, the obols, continued, tending to decline in fineness, and their types, except for the cross pattée, were of Carolingian derivation. His kingdom was limited to the northern centre of France, and feudal deniers began to appear in abundance elsewhere: the most important and numerous were those issued from the 10th century by the abbey of St. Martin at Tours with a "castle" type destined to exert wide influence. This *monnaie tournois* was lighter than the royal *monnaie parisis*, generally at the ratio 4:5. Louis IX in and after 1262 reformed the coinage. The sou, hitherto a coin of account, became in 1266 the silver gros tournois, $\frac{23}{24}$ fine and weighing about four grams; its types continued the "castle" of the denier tournois but with an arrangement of concentric inscription and ornament, which was frequently imitated elsewhere. With this there appeared a gold écu, with the royal lilies on a shield. Subsequent development down to the 15th century emphasized more and larger gold denominations; silver continued, often debased. Design reached magnificent heights in Gothic splendour, seen in the masse d'or, mouton d'or, ange d'or and franc d'or; the Anglo-Gallic issues of the time were comparably beautiful. Feudal coinage was severely limited, that of Brittany and (at first) Aquitaine being most important, together with a number in Provence. Types in Aquitaine later showed some English influence, while in the gold of the south that of the Florentine florin was noticeable. The 16th century saw the adoption of broad, thick silver coins familiarized by the testons of Italy; these, together with the gold écus, set the general pattern. Early in the 17th century the use of machinery for coining was the subject of experiments by Nicolas Briot; both he and Jean Warin were famous for their technique and style under Louis XIII. The later 17th and 18th centuries, though their coinage was of considerable external magnificence (latterly at the hands of the Roettiers), was not devoid of monetary difficulty and fluctuation. Louis XV s[illegible]

pressed independent local or provincial minting, Strasbourg being the last of such mints to survive, though royal branchmints continued in a number of cities. Under the Revolution Louis XVI coined first as constitutional king, in gold, silver and copper; but from 1793 the issues were wholly republican, with the inscriptions *République française, Liberté,* etc., and the symbols (cap of liberty, cock) that have survived in modern French coinage. The precious metals were in short supply; gold and silver were demonetized and large quantities of paper circulated in their place, together with copper. In 1793 the decimal system was adopted, in terms of francs, decimes and centimes, coins now being dated by the revolutionary era; gold coinage was effectively lacking until the time of Napoleon. From 1866 France was joined with Belgium, Italy and Switzerland in a monetary convention defining the denominations, quality and weight of gold and silver coinage in terms of francs. In the 20th century alloys were introduced, and the Vichy government of Henri Philippe Pétain (whose portrait appeared on some coins) also used zinc, iron and aluminum. From 1950 paper money was increasingly replaced by alloy coins, the "heavy" revalued franc being introduced in 1959.

4. **The Low Countries.**—The Merovingian and Carolingian periods had seen the operation of a few mints. Subsequently the area became distributed among the authority of a number of dukes, counts, seigneurs and ecclesiastics, Luxembourg, Hainaut, Flanders, Brabant and Holland being conspicuous. Their coinages reacted closely to the influence exerted by the neighbouring great powers. In the 16th century the Low Countries passed to the house of Austria, and the daalder made its appearance. English military operations were accompanied by the issue of gold pieces imitated from those of the current English coinage but differentiated by their inscriptions. The 16th century produced some remarkable siege-pieces from Amsterdam, Bergen op Zoom and elsewhere as a result of resistance to Spanish and French pressure. With the establishment of the Kingdom of Holland under Louis Napoleon in 1806, coinage began to conform with that of the Napoleonic empire. Belgium emerged as an independent kingdom in 1831, and from 1886 its coins either have been minted in equal numbers of French-inscribed or Flemish-inscribed specimens or have been bilingual.

5. **Switzerland.**—The coinage of Switzerland illustrates the varying fortunes of this land, its gradual growth and consolidation. First there was the gold money of the Merovingian kings, among whose mints were Basel, Lausanne, St. Maurice-en-Valais and Sitten (Sion). The silver deniers that Charlemagne made the coinage of the empire were issued by fewer mints. The dukes of Swabia began to strike at Zürich in the 10th century, and the empire during the 10th and down to the 13th century granted the right of coinage to various ecclesiastical foundations, bishoprics and abbeys. Bern was allowed a mint by the emperor Frederick II in 1218 and other towns and seigneurs subsequently gained the same right. The demi-bracteate appeared about the middle of the 11th century, and about 1125 it was superseded by the true bracteate, which lasted until about 1300. The 14th century witnessed the rise of the Swiss confederation, and by degrees the cantons struck their own money. These, together with the coins of some few sees and abbacies, formed the bulk of Swiss money of the medieval and modern periods. The separate cantonal coinage, interrupted by the French occupation, was finally suppressed in 1848, when a uniform currency was adopted.

6. **Italy and Sicily.**—At the close of the Carolingian period the coinage of Italy fell into two main classes. In nearly all of the north, including Rome, it consisted of silver deniers of Carolingian derivation, mainly struck at Pavia, Milan, Lucca and Verona. At Venice and over most of the south the dual influences of the Byzantine and Arab empires were prominent. Monetary fashions were shown in the coinage of Sicily struck by the Normans. Robert Guiscard (1075–85) struck gold tari of almost wholly Arabic appearance, together with bronze of Byzantine style. Roger I of Sicily latinized the bronze, and Roger II as *Dux Apuliae* coined silver ducats of Byzantine type; arab-style gold tari still continued for commercial reasons, since the great Fatimid coinage was then the currency of all western Muslims. After southern Italy and Sicily had fallen to German power, Frederick II (1212–50) restored a Latin coinage of gold, of splendid style and execution and good fineness, in proto-Renaissance style. His gold augustale of about 5.2 g. and its half, struck *c.* 1231 at Brindisi and Messina, had as obverse the emperor's laureate bust with inscription *IMP. ROM. CESAR AVG.* and, reverse, the imperial eagle with a continued inscription, *FRIDERICVS.* They were accompanied by billon deniers. Sicily soon passed to Charles I of Anjou (1266–85), and its Angevin coinage, like that of Naples, assumed the beauties of the French medieval style, succeeded in turn by that of the Aragonese kings.

In northern Italy leading cities were issuing silver (with or without the imperial name) with a free choice of types—portraits, badges or figures of patron saints and others, with explanatory legends. Mantua celebrated Virgil; Florence from *c.* 1189 showed its lily with St. John the Baptist; and Genoa, the *janua,* or eponymous gate. Venice, abandoning the imperial name early in the 12th century, set a precedent *c.* 1192 in the issue of the larger silver grosso or matapan, using the henceforth familiar types of Christ on the reverse and, obverse, St. Mark presenting the gonfalon to the doge. The influence of the gold coinage of Frederick II on such cities was soon evident. Genoa was striking gold as early as 1252. Florence at the same time issued the first of its famous and much more profuse series of fiorini d'oro or gold florins. The lily continued as the civic type, together with the standing figure of the Baptist; regular weight (about 3.50 g., 54 gr.) and fineness won the fiorino universal fame and the compliment of wide imitation; double florins were introduced in 1504. Venice followed in 1284 with its gold ducat or zecchino (sequin) of the same weight, with types developed from the former Venetian silver: the figure of Christ is surrounded by an inscription abbreviated from the metrical *Sit tibi, Christe, datus quem tu regis iste ducatus* ("May the sovereignty which thou dost exercise, be accorded to thee, O Christ"). Venetian ducats rivaled Florentine florins in commercial influence and were widely copied abroad, especially in the Latin Orient, multiples being occasionally struck. The series begun under Giovanni Dandolo continued with the names of the successive doges until the early 19th century.

At Rome no papal coins appeared from 984 until purely epigraphic types recorded the names of Leo IX and the emperor Henry III in 1049–1054. Thereafter there was a further gap until Urban V (1362–70). The senate of Rome coined silver deniers from 1188, with the antique legend *Senatus Populus Q.R.* and figures of SS. Peter and Paul. In 1252 Brancaleone struck deniers with the seated figure of Rome and the legend *Roma Caput Mundi;* Charles of Anjou in the 13th century and Cola di Rienzo in the 14th also coined, as Roman senator and tribune, respectively. Senatorial gold ducats were introduced on the Venetian model in 1350. Papal coinage returned from Avignon in 1367 with Urban V, who assumed rights over the mint of Rome; gold, silver and bronze later developed, with types (crossed keys, tiara, personal arms and many different emblems) that with few interruptions have lasted ever since. From 1869 papal coinage has mainly been of a commemorative nature, as is true of the modern papal coinage, in silver, acmonital (stainless steel) and bronze, of denominations corresponding with the Italian state coinage.

The patronage given by the popes to notable artists, *e.g.,* Francia and Cellini, resulted in a fine and often lavish standard of design in their coins and medals. Similar patronage was shown by the noble houses of Ferrara, Mantua, Milan and elsewhere, whose coinages from the 15th century attained a splendid level. The size of gold and silver denominations was growing, as witness the silver teston of 1472 (*testone* means "large head"); and the portraits made by Caradosso, Francia and others of equal fame are among the finest small-scale Renaissance work. Later coins of still larger size of the duchies of Savoy and Florence are remarkable. Italian coinage continued to be divided among a number of kingdoms, principalities and duchies down to 1861, when Victor Emmanuel I first coined as king of all Italy. The metals were gold, silver and bronze; alloys were introduced under Umberto I (1878–1900). Under Victor Emmanuel III (1900–46) reverse types borrowed heavily from the antique, and his later issues reflected the influence of the Fascist regime, being dated by the Fascist era

from 1936 (year XIV) as well as by the Christian. From that same year he appeared as emperor (of Ethiopia) as well as king of Italy, and after 1939 coins were struck for him, with a helmeted portrait, as king of Albania. After World War II the republican coinage of Italy, in aluminum and steel, concentrated mainly on symbols of agricultural fertility and national industry.

7. Germany and Central Europe.—The complex coinages of Germany allow only a very brief sketch of some of their main features. Territorially the German issues began and developed in an area that has since been many times divided, and from which Austria, Hungary, Czechoslovakia and Yugoslavia have emerged as separate powers. Classification of these issues remains one of the most formidable numismatic problems.

From the 10th to the 12th centuries the Carolingian pattern of coinage was continued; but with the advent of the Swabians under Conrad III in 1138 unity disappeared. In the west the silver denier continued. In the east the coinage of bracteates was developed—silver coins of much lighter weight and so thin that they bore only a single type, repoussé on the reverse, for which a special technique (including the use of wooden dies) was devised. The western deniers were in part from imperial mints, scattered among a much larger number of feudal mints, representing ecclesiastical rather than lay authorities. Westphalia produced a profuse ecclesiastical coinage; that of Cologne was especially important, showing the former Carolingian "temple" combined with the linear inscription *S(ancta) Colonia A(grippinensis)*; and that of Münster was comparable in influence. This area was conservative and prosperous: the weight of its deniers was well maintained, and although Anglo-Saxon and, later, English and Byzantine influences became noticeable, its types showed little tendency toward major change.

In the eastern region a sharp decline in weight led to the thin, single-type bracteates, and the designs quickly broke away from Carolingian tradition. Issued by a wide variety of authorities, many of them ecclesiastical, these coins showed a great range of human figures and portraits (saintly and secular) together with representations of churches, castles and heraldic devices in an essentially medieval Germanic style. Difference between the heavier western deniers and the lighter eastern bracteates was perhaps partly responsible for the emergence of the mark. This weight of solid silver, the mass of which varied from one time and area to another, stood at about $\frac{2}{3}$ of the gold pound, which equaled 240 western silver deniers.

Transition from medieval to modern coinage took place with the emperor Louis IV of Bavaria (1314–47), who introduced gold and multiplied the silver grossus already issued (with adaptations from the gros of Tours) by Cologne under Henry VII (1308–13). Louis reduced the number of purely imperial mints. Those which operated by rights granted to the nobility, the churches and certain municipalities were still very numerous, and from these henceforth appeared the bulk of German coinage, including from 1520 the large silver thalers (so called from the Joachimsthal mines in Bohemia). In the 16th and 17th centuries the thalers and their multiples, of handsome and even ornate appearance, with, obverse, portraits and, reverse, elaborate heraldic devices, dominated the silver currency of Germany, rising in value as minor coins were debased. Thalers of Saxony and Brunswick are specially well known. The thaler continued as a unitary denomination down to the 19th century in Germany proper, but in 1870 German adherence to the gold standard caused its abandonment. From 1870 the kings of Prussia as emperors coined for all Germany: henceforth the innumerable local variations in coinage were subsumed under the gold reichsmark of 100 pfennigs, the silver standard being abandoned. After World War I the rulers of German states abdicated or were deposed, and everywhere the value of the mark declined to zero, its place being momentarily taken by inflated paper currencies. Silver was coined mainly for commemorative pieces between World Wars I and II, including the Hindenburg portrait-pieces; zinc, aluminum and alloys furnished the wartime currency of 1939–45. After 1948 the coins of western Germany were inscribed *Bundesrepublik Deutschland;* those of eastern Germany, *Deutschland* alone (with emblems of industry and fertility).

In Austria there was a ducal silver coinage in the 11th centur[illegible] It remained crude until the 14th century, when Albert II [illegible] 58) introduced a gold florin of Florentine character. The gro[illegible] peared with Frederick III (1440–93): thereafter developmen[illegible] parallel with that of Germany, with thalers taking a promin[illegible] place. Those with the portrait of Maria Theresa acquired [illegible] popularity on either side of the Red sea. They continued [illegible] coined in large numbers at Vienna and London, with the date [illegible] for circulation in those regions: 24,000,000 were struck in 1940–41 from British mints alone.

The Bohemian ducal coinage of deniers from the 10th to the 1[illegible] centuries showed the mingled influences of Byzantine, Scandina[illegible] vian and even English models; by the 12th century the Prague mi[illegible] was developing its own style. Wenceslas II first produced the gros in 1300, and John of Luxembourg (1310–46) the first gold f[illegible] with, obverse, crown and, reverse, rampant lion. The regal coin[illegible] age of Hungary began with the deniers of St. Stephen (1001–38), and the style remained crude until Charles Robert of Anjou (1309–42)—Carobert—reorganized the monetary system with a [illegible] bearing gold florin and a silver gros modeled on those of Naples and Rome.

With the formation of the Austro-Hungarian empire in 1848 the coinage of the two countries, including Bohemia, was unified During 1857–68 the coinage conformed to the terms of a monetary convention with Germany. The coins of Austria and Hungary were differentiated from 1868: the former were inscribed in German or Latin, and the latter in Magyar. Since 1923 the republican coinage of Austria, well designed, has been conspicuous for its commemorative silver coins. That of Hungary, under the regency of Adm. Miklós Horthy, emphasized the historic crown of St. Stephen; under Soviet domination the types have concentrated on symbols of revolution, peace, fertility and industry, together with special types for silver, showing notable public buildings in Budapest.

Czechoslovak coinage from its inception in 1918 has shown the lion of Bohemia: special coinages have commemorated St. Wenceslas (in gold) and Tomas Masaryk and—since the Soviet occupation—Stalin (in silver). The republic of Yugoslavia, similarly an offshoot of Austria-Hungary, has a currency based on paras [illegible] dinars. That of Albania, until its domination by the U.S.S.R. drew heavily on classical Greek traditions for its range of types.

8. Scandinavian Countries.—The origin of the coinage of the Scandinavian states, Norway, Denmark and Sweden, is clearly English and due to the Danish conquest of England. The Runic alphabet was employed, though not by any means exclusively, on many of the early coins of Denmark and Norway. The Norwegian series began with Haakon the Great (*c.* 970–995), who copied the pennies of Aethelred II. In the second half of the 11th century a coinage of small, thin pennies began, which developed into bracte[illegible] Magnus V (1263–80) restored the coinage, more or less imitating the English sterlings of the time. The money of Denmark began with pennies of Sweyn I (985–1014), which were copied from the coinage of Aethelred II; the coins of Canute (Cnut) the [illegible] (1014–35) and Hardicanute (Hathacnut) (1040–42) were [illegible] English in character. With Magnus (1042–47) other influe[illegible] especially Byzantine, appeared, and the latter was very strong [illegible] der Sweyn Estrithson (Svend Estridsen) (1047–76). Bracte[illegible] came in in the second half of the 12th century. The coinage [illegible] difficult to classify until the time of Eric of Pomerania [illegible] There were important episcopal coinages at Roskilde and [illegible] in the 12th and 13th centuries. Sweden had very few [illegible] coins; they began with imitations by Olaf Skötkonung (99[illegible] of English pennies and included the usual bracteate coinage [illegible] The money was restored by Albert of Mecklenburg (13[illegible] The thaler was introduced by Sten Sture the younger [illegible] 20). The money of Gustavus Adolphus (1611–32) is histor[illegible] interesting. Under Charles XII (1697–1718) there was [illegible] curious money of necessity: the daler was struck as a small copper coin, sometimes plated, and the types included Roman divinities. At the same time and later there was a large issue of enor[illegible] plates of copper, stamped with their full value in silver mone[illegible] a countermark.

The modern coinage of Norway—an independent kingdom from 1905—is, like that of Denmark, remarkable as including certain denominations pierced with a central hole. That of Sweden has included some large commemorative pieces of silver. In Denmark the Copenhagen mint has produced a colonial coinage for Greenland. Iceland, formerly joined with the Danish crown, has struck republican coins since 1944.

9. Poland.—After monetary beginnings derived from Germany, Poland developed a 16th-century coinage in gold, silver and billon that reflected its status as the greatest power in eastern Europe: its thalers were especially remarkable for fine portraiture and decoration, including the superb pieces coined by Danzig after 1567 when this area sought Polish protection. Dismemberment of Poland in the 17th and 18th centuries was followed by fluctuations in status, which have continued ever since. The coinage of independence after World War I celebrated national symbolism and national heroes, whether living, like Jozef Pilsudski, or dead, like Jan Sobieski III. On the coins produced during German occupation in World War II and under Soviet control thereafter, the Polish eagle has been a prominent emblem.

Danzig struck its own coinage (in pfennig and gulden) while a free city (1920–39).

10. Russia and the Balkans.—The earliest Russian coins began with the princes of Kiev in the 10th century and showed strong Byzantine influence. The staple coinage later came to consist of small silver kopecks and their halves (dengi); these were of Mongolian derivation, and the earliest bore on one side the khan's name and title in Arabic and on the other the name of a tributary grand prince in Russian, together with some figure-device. The names of the khans were omitted as the power of the princes grew. Ivan IV (1547–84) standardized the types of the dengi as "Tsar and Grand Prince of all Russia," showing a uniform design of a mounted lancer. From the 15th to the 17th centuries there was continuous monetary difficulty, reflected by clipping and counterfeiting, until reforms began in 1654. Peter the Great (1689–1725) reorganized the currency: gold was coined regularly from 1701, and silver rubles and billon kopecks also appeared, together with copper fractions. In 1725, after his death, copper "plate money" was briefly produced (as in Scandinavia) at Ekaterinburg. Recoinage on a large scale occurred in 1741. Under Catherine II (1762–96) copper rubles of great size were briefly struck, and from this period substantial five-kopeck pieces were in common production; the same reign saw a Russian copper coinage in Georgia. In the 19th century Russian coinage followed conventional lines apart from the short-lived introduction in 1828 of platinum (at about $\frac{2}{3}$ the value of gold) for pieces of 3, 6 and 12 rubles. The silver ruble, however, remained the monetary basis, worth 100 kopecks. Soviet issues since the revolution have been mainly of bronze and alloys, with scarce silver and, very rarely, gold; types have usually included such symbols as the hammer and sickle and the star, together with allusions to industry and agriculture, though the Russian eagle was used at first.

Finland, under Russia, struck in gold, silver and bronze down to 1917; since then, as Suomi, its coins (using the Roman alphabet) have shown the Finnish lion. Latvia coined as an independent state from 1918 to 1940. Lithuanian independence, similarly until 1940, was reflected in autonomous coinage, with the type of a galloping knight.

The medieval coinages of the northern Balkan states are of great morphological interest. They are chiefly silver grossi, showing a mixture of Byzantine and Venetian influences. The Bulgarians had a regular silver coinage from Ivan Asen I (1186–96) to Ivan Shishman (1371–95). Modern Bulgarian coinage began in 1879. The Serbian coinage lasted from Vladislav I (1234–40) to the middle of the 15th century. There was also a coinage of the bans of Bosnia (late 13th to 15th centuries). The independent city of Ragusa is remarkable for the bold style of its early copper (13th century, inspired by Roman models of the 4th century) and the richness and variety of its later issues.

In Rumania a princely coinage from 1866 became a royal one, of orthodox pattern, from 1881; the 20th-century types, until the fall of the monarchy in 1947, were remarkably varied. That of Greece began in 1828 with the republican government set up after the battle of Navarino: the basis was the silver phoenix of 100 lepta. This was followed, under the monarchy from 1833, by the drachma of similar value. The 20th century (including the period of republican government) emphasized the types of ancient Greece, though modern issues have broken from this tradition.

11. The Later Byzantine Empires.—From the time of Basil II (976–1025) the Byzantine coinage entered upon a stage of development that, in contrast to what had gone before, showed medieval tendencies. The fabric of the gold nomismata and also of the silver began to change, from using a narrower, thicker blank (flan) to one wider and thinner, which was also given a curious cup-shape, hence the name "nummi scyphati"; gold scyphati declined in purity until, under Nicephorus III (1078–81), they were very base. Silver remained generally scarce; the issue of bronze became uneven. New conventions in legends and types were introduced: Constantine IX (1042–55) showed on his silver an invocation to the Virgin in iambic trimeter; and an invocation used by Romanus IV (1067–71) took the form of a hexameter, carried over from obverse to reverse. This latter issue was notable also for a very beautiful representation of the Virgin standing with the Child in her arms. Figures of the saints appeared in the 12th century, first St. George, and then SS. Theodore, Demetrius and Michael. At the same time the intrinsic quality of the coinage had sunk to a level of desperate confusion, seen most plainly under Alexius I Comnenus (1081–1118), whose "gold" was sometimes no more than billon or even bronze. Under Michael VIII (1261–82) and Andronicus II (1282–1328) the emperor was shown kneeling to be crowned by Christ, with a remarkable reverse type of the Virgin amidst the walls of Constantinople. The influence of western types was seen powerfully in the bronze struck by Andronicus II with, reverse, a cross pattée surrounded by a circular inscription within a double border. Western influence continued in the 15th century, especially under John VIII Palaeologus, whose visit to Italy in 1438 (when Pisanello made his splendid portrait medal) doubtless familiarized him with the designs of the grosso and gros, imitated unmistakably on John's silver with double bands of concentric lettering. By this time the Byzantine idiom in coinage was virtually dead, and it had become more truly a late medieval coinage.

The capture of Constantinople by the Crusaders in 1204 saw the power of the Byzantine empire split among a number of smaller authorities, of which the "empires" of Thessalonica and Nicaea were short-lived: in both the coinage (where it can be attributed with certainty) was of normal Byzantine character. The empire of Trebizond, however, continued a separate existence until 1461, and its small silver Byzantine-style pieces, called "Comnenian white money," were prized for their purity and enjoyed a wide currency. It was through such means that the influence of Byzantine types was exerted on the contemporary coinages of Armenia and elsewhere in Asia Minor. (C. H. V. S.)

VI. UNITED STATES COINS

The first coins struck in the North American colonies were silver shillings, sixpences and threepences, made by John Hull and Robert Sanderson, silversmiths, at a mint in Boston from 1652 to 1682, by order of the general court of Massachusetts Bay colony. This mint dated its coins 1652 over the entire 30-year period to conceal the continuous mintage from British authorities in London.

With very few exceptions, the coins circulating in the colonies until the Revolution were unauthorized private issues or old worn coppers no longer acceptable in England or Ireland. Silver was rare (consisting mainly of Spanish and Mexican dollars) and gold almost nonexistent. Copper was then a semiprecious metal, and in theory (though seldom in practice) 24 copper halfpence contained a shilling's worth of copper. Some of the colonies, notably those in New England, repeatedly experimented with paper money with disastrous results. Ostensibly to satisfy the colonists' needs for metallic currency, but in reality for the benefit of Cornwall mineowners, the Royal mint in 1688 issued tin farthings bearing the image of James II on horseback and the curious denomination of $\frac{1}{24}$ of a Spanish real. The Rosa Americana pieces, struck by

William Wood of Wolverhampton under royal patent dated July 12, 1722, received a disappointingly small circulation in New York and New England. Another coinage by Wood in 1722–24, intended for Ireland but rejected there because of scandalous circumstances surrounding his purchase of the royal patent (which was furiously attacked by Jonathan Swift in his *Drapier Letters*), was shipped to the North American colonies. Later these coins were supplemented by quantities of lightweight imitation halfpence, made principally in Birmingham, Eng. Alone among the colonies, Virginia (because of a provision of its 1606 charter) had an official copper coinage executed at the Royal mint in 1773. New Hampshire authorized one William Moulton to make coppers in 1776, but the number was extremely small. The continental congress uttered pewter dollars in the same year to provide moral support for its inflated paper currency. These bore a sundial, the word Fugio, the motto Mind Your Business and 13 links for the united colonies.

The end of the Revolution in 1783 occasioned the manufacture and circulation of immense quantities of British copper tokens designed for the American trade—many bearing fanciful portraits of General Washington. Between 1785 and 1789 the Republic of Vermont and the states of Connecticut, New Jersey and Massachusetts awarded contracts to various individuals to strike copper coins, and congress similarly licensed James Jarvis in 1787 to make cents of the same design as the 1776 dollars. All these ventures were failures, the authorized coins being driven out of circulation by British tokens, Birmingham halfpence and the lightweight issues of "Machin's Mill" (a clandestine mint near Newburgh, N.Y., which imitated state coppers and British halfpence). The copper panic of 1789–90 followed, coppers of all kinds dropping to 72 to the shilling from their former 14 or 15.

Congressional efforts to establish a national mint had resulted in the issue of the historic 1783 Nova Constellatio silver patterns of 1,000, 500 and 100 units, from dies by the Englishman Benjamin Dudley, exemplifying the extraordinary Morris plan, which reconciled the diverse colonial moneys of account. In 1786, however, congress adopted instead the Jefferson proposals for a decimal monetary system based on the dollar, and in 1792 the mint was finally built in Philadelphia, with David Rittenhouse as director. Jefferson tried vainly to hire as die engraver a Swiss, Jean Pierre Droz, who nevertheless furnished dies, hubs and presses. Before the mint was quite ready, the first official American silver coin, the half disme, was struck in Oct. 1792 in John Harper's cellar a short distance away, from dies by Robert Birch and Joseph Wright, who were also responsible for the regular cents and half cents of 1793. Silver followed in 1794 and gold in 1795, the engraver being Robert Scot.

Later designers of American coins included Gilbert Stuart (1796 silver), Titian Peale and Thomas Sully (the 1836 dollars engraved by Christian Gobrecht), Augustus Saint-Gaudens (1907–33 ten- and twenty-dollar gold pieces, called eagles and double eagles), Bela Lyon Pratt (1908–29 half eagles and quarter eagles), Victor Brenner (the Lincoln cent), James Earle Fraser (the buffalo nickel), A. A. Weinman and Hermon MacNeil (1916 silver), John Flannagan (1932 quarter dollar), Laura G. Fraser, Chester Beach and Gutzon Borglum (various commemorative coins).

The discovery of gold and silver in various regions and the difficulty of transporting large quantities of bullion through country menaced by Indians and bandits prompted the founding of both private and federal local mints. The Bechtlers of Rutherfordton, N.C., coined locally mined gold long before the government built a mint in Charlotte. The California gold rush stimulated coining by many bankers and assayers. Private coinage was legal so long as the coins contained full bullion weight and purity and imitated no official issues; Bechtler and Moffat gold (the latter coined by Moffat and Co. at San Francisco) circulated at about par until the Civil War, while lightweight private gold took a discount. The California private mints mostly ceased operations when the San Francisco federal branch started, but those in the less accessible regions of Colorado continued long afterward, and as late as 1901 one Joseph Lesher struck octagonal silver dollars in that state.

In the period 1851–1900 occurred many brief experiments with

Official Colonial and United States Mints

odd denominations: bronze 2-cent, nickel and silver 3-cent and silver 20-cent pieces; an overweight silver "trade" dollar designed for use in trade with the Orient; gold three-dollar and four-dollar coins. All proved superfluous. A law of 1873 discontinued the silver dollar until political pressure from mine owners forced through congress an 1878 act requiring the mint to buy 2,000,000 to 4,000,000 oz. of silver monthly and coin the entire amount into silver dollars. Coinage was discontinued in 1935. Millions of the silver dollars long remained stored in banks and treasury vaults but eventually they became scarce and in 1964 a new minting was authorized. Gold was recalled in 1934, but gold coins of numismatic interest may be retained in any quantity by "collectors of rare and unusual coin" (presidential order 6260). By an act of 1853 all silver coins except the dollar are fiduciary; *i.e.*, lightweight and current by government authority rather than bullion value. The passing of 19th-century artistic canons has been reflected in American coin designs, which since 1909 have portrayed statesmen rather than personifications of liberty. All the above influences have combined to make the 20th-century American coinage system the simplest in use in any major nation. (W. H. Br.)

VII. COINS OF THE BRITISH ISLES, COLONIES AND COMMONWEALTH

1. Ancient Britain.—The earliest coinage of Britain consisted of small, cast pieces of speculum, a brittle alloy with about ¼ tin and ¾ copper. These coins copied the bronze of Massilia of the 2nd century B.C. and circulated, mainly in southeast England, early in the 1st century B.C.; their relationship with contemporary iron currency-bars is uncertain. At the same time uninscribed gold coins of the Gaulish Bellovaci, imitated from the famous gold stater of Philip II of Macedon (obverse, Apollo head; reverse, chariot), were being introduced, probably by trade. The first Belgic invasion, *c.* 75 B.C., brought variants of these, from which arose a complex family of uninscribed imitations; the study of their distribution in Britain has ascribed them to more or less well-defined tribal areas in the south and east; some are crude, but the best illustrate the peak of Celtic art in Britain. The gold was of variable quality. After the second Belgic invasion (following Caesar's reconnaissance in 55 B.C.) the coinage entered a historic phase through the addition (in Latin, and with Roman titles) of the names of kings. Roman influence under Augustus prompted the introduction of silver and copper to reinforce the gold (of varying purity) and the Romanization of previously Celtic types. Claudius' conquest in A.D. 43 ended native coinage, except for crudely cast billon pieces long continued in Hampshire and Dorset; the gold of the Brigantes in Yorkshire was the last to disappear.

2. Roman Britain.—Unofficial copies of Claudian bronze were produced in Britain to alleviate shortage of token coinage after the Conquest. Thereafter no coinage, official or unofficial, was produced until the reign of the usurper Carausius (A.D. 286–293), who coined profusely in orthodox Roman fashion at London and elsewhere in gold, silver and copper; the same was done briefly by Allectus (A.D. 293–296). Diocletian's London mint was continued under Constantine until A.D. 324; thereafter, except during the usurpation of Magnus Maximus (A.D. 383–388), Britain lacked a

official mint, being supplied with coinage mainly from Gaul. Imitative bronze pieces, however, which had first appeared in the 3rd century, continued to be made in the 4th. Sometimes these were of crude style and small size, and it is possible that in their crudest and smallest form (like those found at Lydney) they remained in partial currency in the 5th century after the Roman evacuation.

3. Early Anglo-Saxon Coins.—Infiltration of Merovingian gold from France in the 6th century (together perhaps with Runic-inscribed pieces from farther east) prompted the issue of Anglo-Saxon gold "thirds" in the 7th; solidi were only very rarely struck owing to their high intrinsic value. Output, never great, was confined chiefly to the London-Kent area. The London mint, almost certainly episcopal, signed its coins (obverse, facing head; reverse, cross) with the name *LONDVNIV;* Kentish coinage (whether from Canterbury or elsewhere) was mainly regal; in addition there was a perhaps small Mercian series and another from York. A further series, copied from late 4th-century Roman prototypes, was struck *c.* 650 when the gold content was fast diminishing. Gold coinage soon gave way to that of small silver sceats (about 1.29 g., or 20 gr.) of essentially different style. Some had Runic legends, including the name, supposedly, of Peada, king of Mercia (fl. 656); most, however, were nonregal, and their legends, where they exist, *e.g.*, on coins bearing the name of London, are latinized. Types were very varied and some almost certainly originated in Frisia, where sceats are found in large quantities, denoting the trading connection that called for their use; these show animal and floral design. In the south the sceats lasted until *c.* 800. Similarly small silver sceats were developed (at first with animal designs) in the middle of the 8th century in Northumbria, where they quickly gave way to copper, which lasted for about a century and showed the plainest possible types—a central cross on each side surrounded by the names of kings from Egfrith (670–685) onward or of archbishops or moneyers. This northern series ended *c.* 850.

4. Anglo-Saxon Penny Coinages.—English coinage proper begins with the silver penny of Offa, king of Mercia (757–796); first struck at around the weight of the sceat and, from about 790, up to about 22½ gr. (equal to 240 to the Tower pound). The new pennies showed Carolingian influence in their broad, flat forms. Their designs, however, insofar as they were not influenced by late Roman coin-portraiture, displayed a brilliant originality (both in Anglo-Saxon portraiture, freely conceived and delicately modeled, and also in pattern design and decorative lettering), which had no equal for some centuries. Offa's coinage, though minted expressly for him as *Rex Merciorum,* was mainly current in the southeast and was probably struck at Canterbury, which had contained a mint (responsible for a first penny-coinage under Aethelberht II, 748–762) until the battle of Otford brought Kent under Mercian suzerainty. Evidence for this lies in the fact that the moneyers of Offa were also those of the kings of Kent, and the coins of archbishops of Canterbury, including Jaenbeorht (died 792), bore the names of Offa and his successor Coenwulf: under Ceolwulf (821–823) the mint-name of Canterbury appeared on the coins. Offa struck pennies with the portrait and name of his wife Cynethryth as *regina M(erciorum)* and also issued, doubtless for presentation purposes, gold pieces copying a 774 dinar of the caliph al-Mansur but with the addition of *OFFA REX.* Ceremonial gold coins, like Offa's, all now represented by unique examples, were minted, perhaps partly for use in paying the Romescot, by Archbishop Wigmund of York (837–854?), Edward the Elder (899–924), Aethelred II (978–1016) and Edward the Confessor (1042–66).

Offa's coinage, with, obverse, king's name (with or without portrait) and, reverse, decorative ornament with moneyer's name, influenced design under the kings of Kent and East Anglia, though there was a growing tendency to employ on the reverse an inscription in three lines or around a central cross. This is seen in the coinage of the Wessex kingdom, which was produced first at Winchester, then, after the battle of Ellendun in 825, at Canterbury, still the only permanent mint south of the Humber. Under Aethelwulf (839–858) a uniform type of coinage was achieved for all southern England except East Anglia. The Viking invaders, from *c.* 870, left an important mark on English coinage, including the use of the "London monogram" by Halfdene, who occupied the city in 872, and new designs of north-European derivation. York was their principal mint, together with Lincoln, from which numerous memorial coins of SS. Peter and Martin were issued. Meanwhile Alfred (871–899) greatly extended the Wessex kingdom, as shown by his operation of mints: Canterbury (still much the largest), Gloucester, Exeter, Winchester, London and Oxford (the last sometimes disputed). His coins (which included fractions of the penny) were of careful workmanship and showed Viking influence in their design. The 10th century saw the power of English kings spread quickly northward. Under Aethelstan (924–939), who could use the title *Rex totius Britanniae* with justification for the first time, there were nearly 30 mints at work, mainly southern and central but reaching up to Chester; under Edgar (959–975) there was much more uniformity of type. The Council of Grateley under Athelstan had enacted that each permitted mint was to have but one moneyer, with certain specified exceptions; *e.g.*, London had eight. By the time of Aethelred II more than 70 mints were at work; London, Winchester, Lincoln and York were the largest and most profuse. From about this time the types were generally standardized: obverse, king's portrait and, reverse, some cruciform design. Regional differences of style or treatment superseded the earlier predominance of Canterbury, due perhaps to the regional production and distribution of coining-dies.

5. Post-Conquest Coinage.—The Norman Conquest made little change in the mint system or in the coinage (though the facing portrait acquired great popularity); the pre-Conquest moneyers stayed in office and struck coins for William I. After his reign the number of mints tended to decline. The pennies of William II have nothing in their legend to distinguish them from his father's issues, but it is possible to allot eight types to William I and five to his son. Forgery gave Henry I much trouble, and one step he took to prevent it was to issue his later coins with a snick in the edge to show that the silver was good. He also coined round halfpence: previously silver pennies had had to be halved to produce a smaller denomination. The civil wars of Stephen's reign produced many interesting coins, such as those struck in Matilda's name as *Imperatrix* and the pennies of Eustace Fitzjohn and other barons, very much on the pattern of feudal issues in France.

Henry II ceased the regular change of types customary since William I's reign and struck one type till 1180. As a result the work of the English mints reached its lowest level; the coins frequently have only a letter or two of the legends and fragments of the type. His short-cross penny, so called from its reverse design, first issued in 1180, remained unchanged—including the name *Henricus*—not only by Henry II but also by Richard and John and Henry III till 1247, when Henry III coined the long-cross penny with the arms of the cross extended to the edge of the coin to discourage clipping. He also reduced considerably the number of mints. Edward I subordinated all mints to the authority of the master-worker in London, William de Turnemire. In 1279 he introduced a new type of penny, with, obverse, bust of the king and, reverse, long cross with three pellets in each angle, a type that was much imitated abroad and persisted on silver till Henry VII. The moneyers' names disappeared from the reverse legends, and their place was taken by the name of the mint; *e.g., CIVITAS LONDON,* etc. Edward I also struck halfpennies and farthings to replace the cut pennies that had hitherto done duty for small change. He also introduced a groat, or fourpenny piece (groat = gros or grossus of European coinage), but this larger coin did not establish itself till Edward III's reign. The coins of Edward I, II and III cannot be distinguished by their legends; a minute study of detail has, however, enabled them to be attributed satisfactorily. Privileged ecclesiastical mints still continued active.

Henry III had attempted in 1257 to issue a gold coinage by striking the gold penny (45 gr.) of the value of 20 pence silver, later raised to 24; but the difficulty of rating gold to silver proved insuperable, and the coinage was withdrawn. In 1344 Edward III issued his fine gold series: florin, leopard and helm (½ and ¼ florin), all with the scriptural legends henceforth popular, but his effort to introduce a gold currency was without success. The attempt was renewed with the noble (struck at London and, later, at Calais),

and, after various experiments with its weights, a gold coinage was finally established in currency in 1351 with a noble of 120 gr. of gold and its subdivisions, the half- and quarter-noble. In the same year the silver penny was reduced to 18 gr. and the groat issued (on Flemish models). The noble was valued at 6*s*. 8*d*. The obverse type of the noble, the king in a ship, is supposed to allude to the naval victory of Sluis. The reverse type is a floreate cross with considerable ornamentation. The weight of the noble was reduced by Henry IV in face of foreign competition. Edward IV distinguished his noble by a rose on the ship (rose-noble or ryal) and raised its value to 10*s*., while a new gold coin, the angel, was introduced to replace the old value of the noble at 6*s*. 8*d*.; the penny was reduced to 12 gr. The angel is so called from its type of St. Michael and Lucifer. The reverse is a ship with a cross in front of the mast. (In the 16th century the angel became the piece given to those touched for king's evil [*q.v.*]. It was struck for this purpose down to the reign of Charles I, and small versions were struck by the later Stuarts and pretenders, but it was not again issued as legal tender.)

The next important change in the coinage was not till the reign of Henry VII. This was the introduction in 1489 of the sovereign, a splendid gold coin of 240 gr., current for 20*s*., with, obverse, the king seated on an elaborate throne and, reverse, a Tudor rose with central shield of arms. He also issued (certainly by 1504) the first English shilling or teston, a handsome coin with a fine portrait by Alexander of Brugsal, but this did not attain much currency. Henry VII altered the types of the smaller silver coins by replacing the three-centuries-old cross and pellets by a long cross and shield, while the inscription *POSVI DEVM ADIVTOREM MEVM* took the place of the mint legend; the stereotyped bust was replaced on the groat by an excellent profile portrait and on the penny by the king seated. Henry VIII debased the gold coinage and reduced the weight of the sovereign, the reverse type of which was now the royal arms supported by a lion and dragon. He introduced the gold crown of 5*s*., with its half, raised the angel to 7*s*. 6*d*. and introduced the George noble to take its old value of 6*s*. 8*d*.—so called from its type of St. George and the Dragon. In 1544 he issued the base shilling or teston of 12 pence and debased the silver coinage. When Edward VI again restored a coinage of fine silver, he introduced the silver crown of five shillings (the first English coin dated in arabic numerals), which took the name of the gold piece of the same value introduced a few years earlier. The reign of Mary is notable for the appearance of the portrait of her husband, Philip II of Spain, on the shilling.

Elizabeth continued her father's denominations and restored the purity of the silver coinage. She soon discontinued the groat, Edward VI having introduced the silver sixpence and threepence, although she continued its half, the twopence. Her "portcullis," or trade coinage for use by the East India company, appeared in 1600–01. She also experimented with machinery for coinage, although the immemorial rights of the "manual" moneyers delayed its establishment until after the Restoration. James I introduced a number of new gold coins, the most important being the "unite" or sovereign (20*s*.), so called from its legend (*Faciam eos in gentem unam*, "I will make them into one race") alluding to the union of the crowns. In his reign the number of denominations in use reached its maximum. Charles I made no changes in the coinage until the Civil War (when parliament coined in London, and the king's mint traveled with him); the king's financial difficulties added many new coins to the English series. These included 20*s*. and 10*s*. pieces in silver, the large gold £3 pieces of Oxford and the fine Oxford silver crown, by Rawlins, with a view of Oxford below the usual type of the king on horseback; the siege-pieces rudely struck on silver plate at various royalist strongholds show to what straits the king's party was reduced. Under James I and Charles I are found the first English copper coins, the "Harrington" farthings; they were not struck by the king but under contract. From 1649, copper tokens, mainly of farthing value, were produced in large numbers by a wide variety of municipalities and private traders. The coinage of the Commonwealth is remarkable for the simplicity of its types, and this is the only period of English coinage when the legends have been in English. Coins were struck with Cromwell's bust and superscription, but, although not uncommon, they never seem to have been put into currency.

6. Modern Coinage.—The modern coinage dates from the reign of Charles II. After issuing the old denomination of hammered money in the first two years of his reign, he replaced the unite or broad in 1662 by the guinea, so called from the provenance of its gold. This was a 20*s*. piece. It was not until 1717, after various oscillations, that its value was fixed at 21*s*. His silver coins were the crown, half-crown, shilling, etc., all regularly and beautifully struck by Jan Roettier with the new mill that was then established at the mint. In 1672 he introduced the bronze half-penny and farthing with the Britannia type. The finest coin of his reign is not a regular issue. It was the "Petition" crown made by Thomas Simon, engraver at the mint under the Commonwealth, and bears on the edge a petition to the king that he might be given the same office under the new regime. For the great recoinage under William II provincial mints were briefly opened at Bristol, Exeter, Chester, Norwich and York. The coinage of the 18th century calls for no remark, but mention may be made of the practice of recording the provenance of the metal of particular issues, as in the *VIGO* issues of Anne struck from captured Spanish bullion in 1702, the *S*(*outh*) *S*(*ea*) *C*(*ompany*) silver of George I, and the *LIMA* coinage of George II made of bullion brought by Anson from his voyage around the world. The so-called Anglo-Hanoverian coinage from George I to George IV was in fact the coinage struck by them as electors of Hanover. Toward the end of the century the scarcity of government silver was largely made good by Spanish dollars, with or without a bust of George III countermarked upon them, and by tokens issued by the Bank of England. The deficiency in copper, briefly remedied by large "cartwheel" issues, was made up by private issues of vast numbers of tokens. In 1816 the great recoinage took place with the introduction of the sovereign and silver coins each with Benedetto Pistrucci's design, St. George and the Dragon. England was now formally on the gold standard. In 1848, in the reign of Queen Victoria, the 2*s*. piece (florin) was issued and proved a most popular coin. The double florin, which was first issued in 1887, did not take the public fancy; the practical disappearance of the crown piece from circulation also reflects the public prejudice against large coins, though commemorative crowns have remained popular. No United Kingdom coinage was circulated for Edward VIII.

The gold sovereign disappeared from internal currency in 1914, soon after the outbreak of World War I, after a career of 300 years (as sovereign, unite, guinea and again sovereign), but it has continued to be struck in irregular quantities for export abroad where it has had to compete with forged copies. Silver was alloyed up to 50% in 1920 and since World War II has given way to cupro-nickel: the silver threepence has been replaced by an angular coin of nickel-brass.

Coinage of royal maundy money, continuous since the 18th century, is still maintained with the annual issue of silver pieces of 1*d*., 2*d*., 3*d*. and 4*d*.: the English silver penny and groat thus still survive.

Wales has had no independent coinage, except perhaps for the penny of Howel Dda (*c*. 904–949/950), Saxon in style and struck by the moneyer Gillys, who worked at Chester for Edgar: the penny attributed to Llewelyn (1075–79) is probably a blundered Ruddlan coin of William II.

7. Scotland.—Coinage began by following English usage in regard to types and weights: the earliest silver pennies were those of David I (1124–53) and copied Stephen's, though the use of profile portraits in the 13th and 14th centuries showed an interesting divergence. Gold nobles and silver groats were issued by David II in 1356–57 on the standard of Edward III. From Robert III onward the French or Flemish standard for gold was preferred, and during the 16th century, especially under James V and Mary, a very strong continental influence on design was apparent in a series of gold coins of originality and frequent beauty. Silver coins had begun to show debasement of metal, and as early as James III copper small change—"black" farthings—had been introduced. The Scottish coinage of James VI and I marked a peak in range and variety: after the union of the crowns in 1603 Scots coinage

decreased in quantity and ceased in 1707 after the union of the parliaments. Hitherto the value of Scottish coinage in relation to English was 12:1. Under George VI a shilling with a Scottish reverse was first coined as part of the general English series.

8. **Ireland.**—Irish currency from the 8th to the 10th centuries consisted mainly of Anglo-Saxon, French, Viking and Arabic silver; in the later 10th and 11th centuries silver pennies of the Norse kings of Dublin imitated Anglo-Saxon and Scandinavian models. There were also thin silver bracteates copying Norman types. Anglo-Irish coinage proper began with silver pennies and halfpence of John (the only coins to bear his name, which did not appear on English coins), some with the triangle design, some with the Angevin star and crescent. Dublin, Waterford, Cork, Limerick and Trim were striking silver (increasingly base) from groat down to farthing from the 13th to the 15th centuries. The "three crowns" coinage with the saltire cross (the Fitzgerald arms) beside the shield came in with Edward IV and was continued by Richard III and Henry VII. "Harp" groats were struck at Dublin under Henry VIII (with initials of his queens), followed by his much baser issues. Gold was never coined, but copper was introduced quite early. In Ireland as in England the English Civil War produced a number of siege-pieces, notably the Inchiquin and Ormonde money. James II for his Irish campaign issued his vast "gun-money" series (usually, in fact, of brass), including crowns and half-crowns, to be redeemed in silver when he should regain the throne. Irish coinage was discontinued in 1822; from then on Irish needs were served by English coinage. In 1928 the coinage of the Irish Free State (later the Republic of Ireland) was introduced, with, obverse, harp on all denominations, and reverses bearing a range of animal, bird and fish designs, admirably conceived and delicately executed.

9. **Isle of Man and Channel Islands.**—The Isle of Man first had its own coinage, in bronze, from 1709 to 1733 under the earls of Derby; this was continued, in 1758 only, for the earls of Athol. Regal coinage in bronze appeared intermittently from 1786 to 1839. The characteristic badge was the "three-legs" or triskelis. Since 1840, English issues have been current.

Jersey and Guernsey have had their own bronze coinage for well over a century, showing the shield of three leopards proper to the duchy of Normandy. Variation of types has occurred since World War II, the end of which prompted also the special issue of the Jersey "liberation penny."

10. **Colonies and Commonwealth.**—British colonial issues, begun under Elizabeth I with silver for the East India company, were extended in the 17th century. New England colonists struck the silver "pine tree" and "oak tree" money from 1652; Charles II issued silver rupees at Bombay for the East India company with the company's arms; at the same period silver and copper "hog money" (obverse, boar; reverse, ship) was issued for Bermuda; and James II struck tin coins, with an equestrian portrait, for American plantations.

The 18th century saw few official attempts to provide colonial coinages; thus currency in the British West Indies was based on Spanish, Portuguese and Brazilian gold and especially on Spanish silver dollars, normally cut and counterstamped. Spanish dollars were similarly used in the early 19th century at Sierra Leone. In the 19th century, however, colonial issues proper multiplied. That of the Ionian Islands, from 1819, was among the earliest. In Malta third farthings were issued by William IV and Victoria. Gibraltar had copper from 1842. Farther afield token bronze had been coined for Nova Scotia and New Brunswick from 1823, giving way to official issues later; a general coinage for Canada appeared in 1858. Ceylon's coinage began with bronze half- and quarter-farthings and silver three-halfpence from 1838. The private raj of Sarawak had coinage from 1841, and from 1863 this showed the portraits of the Brooke rajas. Australian coinage of sovereigns started as early as 1855 (the result of the gold rush). In Cape Colony little coinage was produced until the Boer republic of South Africa (which produced Paul Kruger's portrait-coinage of gold, silver and bronze) had been incorporated in the Union. Silver and bronze for Hong Kong began in 1863, and closely succeeding years witnessed the start of colonial issues for Jamaica, Cyprus (with its device of lions on a shield), Mauritius, Zanzibar (an arabic series and thus without portraits in deference to Muslim feeling), North Borneo, Honduras and elsewhere.

In the 20th century the progression of formerly colonial areas to autonomy has produced a contrast between their coinages and those of still colonial character. Coins of the colonies have continued in general to show a crowned bust of the monarch; those of the self-governing commonwealth powers have exchanged a crowned for an uncrowned bust. New Zealand issues, with Maori designs prominent, began only in 1933. Indian and Pakistani coinages, each bilingual (with English retained), have grown out of the former imperial Indian coinage, the British sovereign's head being replaced in India by pictorial designs and in Pakistan by calligraphic and symbolic devices. Regrouping of British possessions in western, central and eastern Africa has necessitated coinage changes, including autonomous issues for Ghana. The coins of the Central African Federation (the Rhodesias and Nyasaland) showed the uncrowned bust of autonomous authority; Nigeria and the east African territories show the crowned bust. Concerning later established coinages of the smaller colonies, mention may be made of that of the Fiji Islands from 1934, often showing a turtle, and of the Seychelles from 1939. In Sarawak the coinage of the Brooke rajas ended with the cession of the territory to the crown in 1946. Finally it may be noted that the issue in 1929 of bronze "puffins" and halves in Lundy Island with the portrait of its owner, M. C. Harman, was held to be illegal.

In general the coins of full commonwealth members and of colonies alike have emphasized on their reverses either national symbols or national heraldic devices, while the inscription around the sovereign's portrait has shown a growing tendency to be rendered in English instead of Latin. (C. H. V. S.)

VIII. COINS OF LATIN AMERICA

1. **The Colonial Period.**—Spanish colonists brought with them to the new world the Castilian currency system, which had been regulated as to standard, weight and size of the coins within a bimetallic pattern by the ordinances of Ferdinand and Isabella issued in Medina del Campo in 1497. The double base of the system were the gold *excelente* (replaced in 1535 by the *escudo*) and the silver *real*. The coins of Spanish America were therefore of gold and silver, that is, the *escudo* and the *real* and their multiples and dividers. The two series were specifically: in gold, the *escudo* (3.38 gms.), two-*escudos*, four-*escudos*, eight-*escudos* or *onza* (the famous gold ounce) and the half-*escudo* or *escudito*, coined in some mints at the end of the 18th century; in silver, the *real* (3.43 and 3.38 gms.), its dividers, the half-*real* and the quarter-*real* or *cuartillo*, and its multiples, two-*reales*, four-*reales* and eight-*reales* (this last known also as the *peso fuerte* or *duro*). During the 16th century, for a brief period, a coin of three *reales* was minted in Mexico. Gold was not minted in a uniform manner until after the second half of the 17th century; until then Hispanic-American currency had been almost exclusively silver coinage. Copper was not minted in Spanish America except in small quantities during the 16th century in Santo Domingo and briefly in Mexico; during the wars of independence it reappeared in emergency coinages.

There are two very characteristic kinds of Hispanic-American coinage, according to the minting technique used: the hammered coin and those of more improved conformation manufactured by means of a minting press or mill. The hammered-down coin of some periods presents a relatively tidy appearance, being very nearly round and containing all the lettering and required symbols, but that of other mintages is frequently of very poor appearance, and only the most essential elements of the design, such as value, identifying sign of the minting house and the mark of the assayer, are distinguishable. These coins of rude mintage are called *macuquinas* (cob). In the 18th century, by ordinances of Philip V, the setting up of adequate machinery for the minting of a perfectly round coinage, with milled and corded edge, became mandatory.

The type of the Hispanic-American coin was very characteristic: its most constant elements were Hercules' Columns and the motto "Plus Ultra," plus the monarchy's coat of arms, either in its en-

tirety or reduced to some of its components, mainly the castles and lions. In edge-milled coinage the same elements were employed in silver pieces, with the addition between Hercules' Columns of an image of the two crowned hemispheres; this was called the *moneda columnaria* (columnar coinage) and was minted until 1772. From that date on, by ordinances of Charles III, silver coinage carried on the face a bust of the reigning monarch and on the reverse the coat of arms, a system already utilized in the gold pieces.

2. Hispanic-American Colonial Mints.—In the beginnings of the colonial period currency was scarce, and very frequently transactions were accomplished through the use of metal foundry pieces; these carried merely the stamp of a royal official, which guaranteed the standard and the fact that the crown's rights had been satisfied. In time several mints were established. Of these, two were of particular importance because of the very large quantities of precious metals, especially silver, minted there: that of Mexico, founded in 1535 and operating until 1821, and the one at Potosí, established *c.* 1574 and operating until 1825. Other minor ones, and their dates of operation, were those of Santo Domingo (1542 to the end of the 16th century and 1818 to 1821), Lima (1568 to 1570, 1575 to 1588, 1659 to 1660 and 1684 to 1824), Santa Fe de Bogotá (1626 to 1821), Guatemala (1731 to 1822), Santiago de Chile (1749 to 1817), Popayán (1732 and 1749 to 1822) and Cuzco (1698 and 1824). Coinage of any of these mints had uniform currency through the entire Spanish empire, and the pieces had uniformity of type. They were distinguished by the symbol of the mint, carried on every coin. The following are some of the symbols used: Mexico, M̊; Potosí, P and, in the edge-milled coins, PTSI and PTS in monogram fashion; Lima, P, L and, in the edge-milled coins, LIMA and LIMAE in monogram fashion; Santiago de Chile, S̊; Guatemala, G and NG (for Nueva Guatemala); Santa Fe de Bogotá, NR (for Nuevo Reino); Popayán, P, PN and P^{N}; Santo Domingo, SD; Cuzco, C° and CUZ.

3. Dissemination of Hispanic-American Coinage.—The larger silver and gold pieces, the eight-*reales* or *pesos fuertes* and the ounces, became in modern times the international currency par excellence. Their dissemination throughout the world was brought about by the uniformity of their standard and milling characteristics. In many countries they were counterstamped in order to adapt them to a local monetary system or to authorize their currency. These counterstamped issues constitute interesting numismatic series. The removal of smaller coins to other parts of the world was generally prohibited in order to avoid a scarcity of this currency.

4. Emergency Coinages in the Era of Independence.—During the wars of independence, between 1810 and 1826, emergency mints were established in different parts of the continent, by the royalists as well as by the patriots. The coinages were almost always crudely designed, being in some instances merely foundry coinage. On other occasions the coins had merely fiduciary value, that is, no intrinsic value at all, as was the case with the numerous coinages of the Mexican patriot Morelos, who produced eight-*reales* pieces in copper. Only in Mexico were there mints of some importance, in ten different localities. The coinage situation became further complicated when the authorities of the opposing forces started counterstamping each other's coins in order to use them within their own camps.

5. The Independent Countries.—The independent states that arose in Latin America after the revolution of 1810 proceeded to mint new coins, but until the middle of the 19th century the bimetallic system established by Spain, with its different units in *reales* and *escudos*, remained intrinsically the same except for the addition of smaller copper fractionary units. After 1850, within a period of about 15 years, all the states adopted the decimal system for their coins, and the *peso* became the unit, though in several cases it took a special name. Within the second half of the 19th century bimetallism became a thing of the past. It was generally replaced by the gold standard, which in the course of the 20th century was replaced in turn by fiduciary currency or paper money, coinages being limited to fractionary pieces or to "merchandise coins."

6. Brazil.—Coins minted in Spanish America circulated abundantly in Brazil from the 17th to the 19th centuries. They were given their official value in terms of the Portuguese *reis*, the corresponding amount being indicated by counterstamping. Hispanic-American eight-*reales* pieces carried an overstamp that was at first of 480 *reis* and that increased until in edge-milled coins it amounted to 960 *reis*. By the end of the 17th century and the beginning of the 18th, mints were established in Rio de Janeiro, Bahia and Pernambuco, but joint circulation of both Hispanic-American and Portuguese coinages continued. The practice of counterstamping disappeared during the first decades of the 19th century, although Hispanic-American eight-*reales* pieces and the equivalent coins of the independent Latin American countries continued to be reminted with the value of 960 *reis* for some time. The Brazilian monetary unit that eventually became the *milreis* was subsequently transformed into the *cruzeiro*, which is divided into 100 cents. (A. DE A.-M.)

IX. ASIATIC COINS

1. Ancient Persia.—*Achaemenids.*—The ancient kingdoms of the middle east, Egyptian, Sumerian, Babylonian, Assyrian and Hittite, had no coined money. The use of coins reached Persia from the Lydian kingdom of Croesus and the Persian satrapies of Asia Minor. The first Achaemenid ruler to strike coins was probably Darius I (522–486 B.C.) as Herodotus suggests. The coins of the dynasty were the daric struck from gold of very pure quality and the siglos in silver; 20 sigloi (shekels) made a daric, which weighed 8.4 gr. The types of both coins were the same: obverse, the Persian king in a kneeling position holding a bow in his left hand and a spear in his right; reverse, only a rough irregular incuse caused in the striking. In shape they were roughly oval, being struck from round or rather egg-shaped globules of metal. These pieces were uninscribed and remained in issue unaltered in type until the fall of the empire. The issue of gold was the royal prerogative, but the conquered Greek and other cities and states were allowed to issue silver and copper while a number of Persian satraps struck silver in their own names. To this latter class belong a number of the earliest and finest portraits on coins. On the fall of the empire, various satraps, such as Mazaeus, who ruled Babylon for his new master Alexander the Great, struck silver coins of their own.

Parthians.—Alexander's coinage and that of the Seleucids were purely Greek in character. In the middle of the 3rd century B.C. the Parthians became a great power in Persia. They had an extensive but monotonous coinage in silver (tetradrachms and drachms) and copper. The tetradrachms and drachms bear the bust of the king on the obverse, and Arsaces, the founder of the dynasty seated holding the Parthian bow on the reverse of the drachms while the usual reverse on the tetradrachms is the king seated receiving a wreath from Victory or a city goddess. The coins do not bear the name of the issuer but that of Arsaces, which was used as a dynastic title. Most of the coins are dated in the Seleucid era; on the later coins the Greek becomes corrupt and is often joined by an inscription in Persian.

Some local dynasties (such as those of Persis and Characene), vassals of the Parthian kings, also struck coins.

Sasanians.—The Sasanian coinage was very extensive in silver, and the early emperors also coined gold, although rarely. The copper coinage also seems to have been small. The coin types throughout the dynasty are the same: on the obverse is a bust of the king with his name and titles, and on the reverse a fire altar, usually with two attendant priests. From the reign of Kobad the reverse legend gives the mint and the regnal year of issue. The standard of the gold coins is derived from that of the Roman solidi; the silver coins are drachms following the Parthian standard and are remarkable for their broad thin form, which was copied by the Arabs for their silver coins. The execution of the portraits in the early coins is remarkably fine but is later debased.

2. Islamic Coins of the West and of Western and Central Asia.—The conquering Muslims at first imitated the coinage of their predecessors. In the western provinces they issued gold and copper pieces imitated from contemporary Byzantine coins, modi-

ving the cross on the reverse of the latter somewhat to suit Muslim susceptibilities. In the eastern provinces the Arab governors issued silver dirhams which were copies of late Sasanian coins (mostly of those of Khosrau II) with the addition of short Arabic inscriptions on the margin and often the name of the Arab governor in Pahlavi; even the crude representation of the fire altar was retained. Toward the end of the 7th century the fifth Umayyad caliph, 'Abd-al-Malik, instituted a coinage more in keeping with the principles of Islam. This "reformed coinage" was of gold (first issued in A.D. 698–699), silver (first issued in 696–697) and copper. The old coin, called dinar (from the Aramaic derivation of the Roman denarius aureus), derived its standard (4.25 gr.) from the Byzantine solidus; the standard of the silver coin (dirham, from the name of the Sasanian coin, which in its turn was derived from Greek drachma) was reduced to 2.92 gr., but it retained in its thin material and style some features of its Sasanian predecessor; the name of the copper change, *fals*, comes from Latin *follis* (a small piece of money). The reformed gold and silver coinage has no pictorial type, only inscriptions, and with rare exceptions this remained the rule in Islamic coinage. This may limit its artistic interest, though the skilful arrangement of the inscriptions often gives it high aesthetic value. Moreover, the inscriptions, which from the earliest time usually contain the name of the mint and date, and in time the ruler's name and title, give the Islamic coins a high historical value.

The reformed dinar and dirham bear on the obverse the Muslim profession of faith: *There is no god but God: he has no associate,* and around it the marginal legend: *In the name of God; this dinar (or dirham) was struck at . . . in the year . . . .* The reverse area has a quotation from Koran cxii, *God is one; God is eternal; He begets not and is not begotten nor is there any one like unto Him.* Around is Koran ix, 33: *Mohammed is the apostle of God sent with guidance and the religion of truth to make it prevail over all other religions averse though the idolators may be.* This type of coin, issued from Spain and Morocco to central Asia, gave Muslim coinage the character that it held for centuries. In mid-8th century the Abbasids overthrew the Umayyad caliphate but at first made little change in the coinage beyond some alterations in the inscriptions. In time the caliph's name was added and, at the provincial mints, that of the local governor, and in the 9th century a second marginal inscription was added: *To God belongs the order before and after and that day believers shall rejoice in the help of God* (Koran xxxi, 3–4).

The Abbasid caliphate broke up in the 9th and 10th centuries, and the succeeding independent rulers regularly put their own names on the coins, although they retained that of the caliph of Baghdad, whose nominal authority was still recognized. Thus in north Africa and Egypt the Idrisids, Aghlabids, Tulunids and Ikhshidids had their own coinage. From the eastern provinces there are the coins of the Tahirids, Saffarids (both in the 9th century), and the Buyids (10th–11th centuries). In central Asia there was the extensive coinage of the Samanids, mainly in silver. In north Africa and Egypt the extensive Fatimid currency in gold introduced a new type of dinar with legends of the usual type but arranged in three concentric circles. In the west the Umayyads of Spain issued a copious coinage from the middle of the 8th to the beginning of the 11th centuries, first in silver only but during the 10th century also in gold; their tradition was continued during the 11th century by the small local rulers of Spain who succeeded them and by the Almoravids, who united Morocco and Spain in one empire.

Islamic gold coinage became one of the great currencies of the medieval world, and the dinar enjoyed great popularity on the western shores of the Mediterranean. It was referred to in Europe in earlier times under the name of mancusus, while the Almoravid dinar was known as morabiti (whence Spanish maravedi). There are also imitations produced; *e.g.*, in Catalonia. The quarter dinars (known as tari) of the Fatimids, who ruled also in Sicily, were imitated in southern Italy and Sicily and by their Norman successors. Enormous quantities of silver dirhams of the various dynasties also reached eastern and northern Europe and more especially Scandinavia, where they are often dug up in great hoards.

The Almohads, who succeeded the Almoravids in the 12th century, introduced a coinage that was new both in its standard and its form. Their fine gold coins (dinar, 2.3 gr.; the more usual coin is the double dinar) count among the most beautiful coins produced in the Muslim world; the dirham (1.5 gr.) is square. The coinage of the Almohads survived also among their successors, well to the end of the middle ages, and was also widely current, and imitated, on the European shores of the Mediterranean.

In the east the successors of the Seljuks (Artukids, Zangids, etc.), who, owing to the scarcity of silver, issued large copper coins, introduced a striking innovation: they adopted a number of different types borrowed from all sources, ancient Greek and Roman, Sasanian and Byzantine. The Seljuks of Asia Minor (12th–13th centuries) had silver coins showing a horseman with a mace over his shoulders, or a lion and sun. Farther east the Ghaznevids (10th–12th centuries), on their conquest of India, struck coins with Sanskrit inscriptions for their Indian dominions.

In the 13th century the Mongols swept through all Asia except India. The khans of the Golden Horde issued an extensive series of small silver coins (which influenced early Russian coinage). The Il-khans of Persia struck large and handsome coins in all three metals (in addition to Arabic legends they bore the khan's title in Mongolian). In the 14th century Timur (Tamerlane) revived the power of the Mongols and struck silver and copper coins. His son Shahrukh introduced a new type of dirham, with, obverse, profession of the faith with the name of the first four caliphs on the margin and, on the reverse, his title.

Meanwhile the new gold coinage of Europe, the Venetian ducat, rapidly spread in the east. It was used as currency up to the 18th century, and its standard (3.56 gr.) was adopted for Islamic coins.

Ottoman Empire.—The original coinage of the Ottomans consisted of small silver coins (akche, called asper by Europeans). Gold coins were not struck before the end of the 15th century; before and after that century, foreign gold, mainly the Venetian ducat, was used. Various European silver dollars also circulated extensively. From the 17th century onward various attempts at reform were made; a notable innovation was the introduction of the *tughra*, an elaborate monogram formed of the sultan's name and titles, which occupies one side of the coin.

Modern Persia, Afghanistan, Turkestan.—The earlier coins of the shahs of Persia were large thin silver pieces of central Asian style, but in the 18th century the form changed, and the coins became smaller and thicker as in India. The legends were usually in the form of rhyming couplets; gold was not common till the 18th century. Cities issued copper with local emblems. Some of the products of the Persian mints were of huge size and were pieces struck for presentation.

The emirs of Afghanistan who became independent of Persia in the 18th century struck gold and silver on the standard of the Mogul emperors, whose poetical legends they also copied. Of the various smaller modern dynasties that ruled central Asia till the Russian conquest, the emirs of Bukhara and of Khokand were notable for their extensive issues of gold pieces. Since the 19th century gradual westernization resulted in the adoption of European styles in currency by the various Islamic countries.

3. India.—*Ancient and Early Medieval.*—There is no reason to doubt the independent origin of coinage in India although it was soon so much modified by Greek influence that the question was long disputed. The earliest coins are pieces of silver, very commonly square, and of copper, punched with various symbols on both sides. Of about the same date are the square and round cast copper pieces with similar but less varied symbols. These pieces circulated all over India and belong to at least the 4th century B.C. From the 3rd century onward there are the copper coinages of numerous states and dynasties, which show increasing Greek influence. Their few silver coins were directly influenced by the hemidrachms of the Greek rulers of northwest India of the 2nd century B.C. The types of these are of considerable mythological and religious interest. Technically they are interesting as showing the evolution of a type from a series of separate punches to the grouping of the punches on a die.

Early in the 2nd century B.C. the Greeks of Bactria began to

invade India, and their coinage is remarkable for its fine series of portraits and for the number of names it records of rulers otherwise unknown. Prakrit legends begin to appear alongside corrupt Greek; the Greek in time becomes more and more corrupt as the Greek rulers were replaced by foreign invaders who copied their types. (The coins of the Saka rulers are conventionally called "Indo-Scythian"; those of the Parthian princes who ruled in what is modern Afghanistan, "Indo-Parthian.") The Greek deities gradually give place to Indian ones on the coins.

In the middle of the 1st century A.D. the Kushans founded a great empire in northwest India; they have left a wealth of gold and copper coins with legends in an Iranian language in a corrupt Greek character. The Kushan coins bear on the obverse the king sacrificing and, on the reverse, deities of all the religions of the time, Greek, Roman, Zoroastrian, Hindu and Buddhist. These types of king on obverse and deity on reverse became the general style of north Indian coinage for the next 1,000 years; the Kushan coinage continued rapidly degenerating till the 4th or 5th century, over a much more limited area; the type was continued by the kings of Kashmir down to the 10th century and adopted and modified by the great Gupta emperors in the 4th century. The latter struck an extensive gold coinage with long legends in poetical Sanskrit and many interesting types, often medallic in nature, but, on their coins for general currency at least, always betraying the Kushan prototype. Among the more notable Gupta coins are those that commemorate Chandragupta's horse-sacrifice or those that record his skill as a lyrist, to which he also testifies in his inscriptions.

In western India a dynasty of satraps of Persian origin had been ruling since the 1st century B.C. Their extensive coinage of silver only is dated and therefore of a historical value unusual in India or any early coinage. This kingdom was overthrown by the Guptas at the end of the 4th century, and they at once began to imitate this silver coinage not only locally but also in their own territory, which seems previously to have had no silver coins. The Ephthalites, who destroyed the Gupta and other civilizations in the 6th century, have left numerous coins, imitated from Sasanian, Gupta or Kushan prototypes. Degenerate copies of these seem to have been the coinages of northern India until the revival of various Hindu dynasties from the 10th century onward. A notable innovation was the neat silver coinage of the Shahis of Gandhara of the "bull and horseman" type in the 9th and 10th centuries, extensively imitated by the Muslim conquerors of India and the contemporary minor Hindu dynasties. The other type favoured by the medieval Hindu dynasties for their gold coinage was that of a seated goddess—going back to a Gupta reverse—and an inscription with the king's name on the other side.

The coinages of southern India form a class by themselves. In the later centuries B.C. and early A.D. the Andhras ruled a great kingdom in central south India; their coinage is mainly of lead and has types of the usual indigenous character.

The later medieval dynasties of south India struck coinages mainly of gold, the type of which is usually the badge of the dynasty; the Cheras of Malabar, for example, had an elephant, the Chalukyas of the Deccan a boar, the Pandyas a fish, and the cup-shaped pieces of the Kadambas bear a lotus. The Chola dynasty introduced under northern influence the type of a king standing on obverse, and on the reverse the king seated, which spread through south India and was taken to Ceylon by the Chola conquest and adopted by the local rajahs there. The great Hindu kingdom of Vijayanagar (Mysore) left a large series of small gold and copper coins with the types of various deities, which had considerable influence on the modern coinages of southern India, including those of the various foreign companies.

Islamic.—The earliest Arab invaders had reached India in the 8th century and founded a dynasty in Sind, which has left numerous very small silver coins of the Umayyad ~~type~~. The coinage of the Ghorid dynasty and its successors from the 12th century onward is varied and extensive, mainly gold and silver tankas (or rupees) of 10.76 gr. They are large thick pieces with the profession of faith on one side and the name of the king, mint and date on the other. A feature of this coinage is the unsuccessful attempt made by Mohammed Tughluq (A.D. 1325–51) to replace gold and silver coinage by brass tokens. Gold was hardly issued at all in the 15th and 16th centuries and for a time the coinage was mainly billon. Sher Shah Sur (1539–45), one of the ablest of his line, issued a large silver currency of a type, carrying the profession of the faith and names of the four caliphs, that was imitated by the Mogul successor of the Surs.

The coinages of Babur and Humayun, the first two of the Mogul conquerors of India, are not extensive and are of central Asian character. With the next two, the Great Moguls Akbar and Jahangir, is found a series unrivaled for variety and, within limitations, beauty—the gold coins of Jahangir are noble examples of Muslim calligraphy. In the 16th century the type that goes back to Sher Shah prevails, the profession of the faith with the names of the first four caliphs and the emperor's titles on the other side. Aurangzeb replaced the confession of faith by the mint and date and this remained the usual type till the end of the dynasty. The emperor's name is usually enshrined in a Persian couplet to the effect that the metal of the coins acquires added lustre from bearing the emperor's name. Nearly 50 such verses are found on Jahangir's coins. The latter's reign is also remarkable for the series of coins bearing the sign of the zodiac, and for the set of portrait mohurs, one of which represents him holding a wine cup. From the beginning of the 18th century the coins become stereotyped and the epigraphy loses its beauty. The English and French East India companies for years copied the native types from the coinages and did not strike on European lines till the 19th century. A uniform coinage for territories under British administration was introduced in 1835. The right of native states to mint their own coinage was gradually curtailed by the British government until there were very few independent coinages. The most important native state mint was Hyderabad. Since 1950 and 1948, respectively, India and Pakistan have had their own coinages.

Miscellaneous.—Mention should also be made of the extensive coinage in gold and silver with Sanskrit legends of Nepal; the coinage of Tibet, related to that of Nepal; the long series of octagonal gold and silver coins of Assam struck until the British conquest; and the brief coinage of Burma in the 19th century.

4. China.—The earliest Chinese coins are small bronze spades and knives, copies of the spades and billhooks and other small articles of husbandry that had been used for barter. The knives (tao) are about six inches long and bear the value and name of authority issuing it; pu money, a modified form of the spades, circulated widely in the 5th and 4th centuries B.C. Small change was supplied by cowrie shells in this period, as it had been long before the invention of a coinage; there was also an issue of bronze imitation cowries. Round money with a hole in the centre was issued about the middle of the 3rd century, but it was not till 221 B.C. that the reforming Shah Huang Ti (221–210 B.C.) superseded all other currencies by the issue of round coins of half an ounce (pan-liang), which were continued by the Han dynasty. This coin became gradually reduced and debased and was replaced in 118 B.C. by the emperor Wu Ti's five-chu piece, which remained the coin of China for the next eight centuries; a break in the monotony of the regular coinage was formed by the archaistic innovations of the usurper Wang Mang (A.D. 9–23), who issued a modified form of the pu and tao currency and a new round coin (ho tsien).

The history of Chinese coins is the history of the gradual debasement of the government currency until it was overwhelmed by the increasing activity of forgers and a new coin was instituted. The five-chu piece lasted till the rise of the T'ang dynasty, when the emperor Kao-tsu in 618 issued the Kai-yuan coin, which gave the coinage of all the far east its form till the end of the 19th century—a round coin with a square hole and a four-character legend of the form "current money of (regnal period)." The Southern Sung dynasty (A.D. 1127–1279) dated their coins on the reverse with regnal years, and the Ming dynasty (A.D. 1368–1644) put the mint name on the reverse, as did the Ch'ing dynasty (A.D. 1644–1912), the latter giving it in Manchu characters. Paper money has been in use in China since the 9th century and was current almost to the exclusion of regular coins under certain Mongol emperors, for example, Kublai Khan, whose paper money is

described by Marco Polo. For over 2,000 years the copper cash with occasional multiples of it was the only coinage of China; gold and silver were current by weight only, the latter in the form of boat-shaped ingots (sycee). The monotony of the series was only rarely broken. With the increasing popularity of Spanish colonial and Mexican dollars as a silver currency in China, several attempts were made to institute a silver coinage in the 19th century; not till the very end of the 19th century were mints established to strike silver and copper coins of European style in all the provinces. One of the last of these, a rupee of Szechwan, was the only coin of the Chinese empire to bear the head of an emperor. This was because it was intended to compete for Tibetan trade with the Indian rupee. Under the republic, coins were at once struck with the portraits of Sun Yat-sen and Yüan Shih-kai, and the various generals who fought for control of China issued their own coins, some in gold, the first in Chinese history. The currency, both of the Chinese people's republic and of Formosa (Taiwan) is the yuan (dollar). The very extensive series of talismans, coinlike in shape but usually larger, should be noted. Many are Taoist and Buddhist in their legends and types; others are simply lucky pieces.

5. Japan.—The art of coinage was borrowed from China by Japan, whose first bronze coins were issued in A.D. 708. Down to the middle of the 10th century 12 different issues were made, each of a different reign. For the next 600 years, however, no government coins were issued, and the currency was supplied by imitations of contemporary Chinese coins made by the great nobles. In the 17th century the copper kwan-ei was first issued, in 1624, and remained in vast variety the usual issue for over two centuries. The ei-raku and bun-kyu sen of the 19th century were the only other regular copper coins. Unlike China, Japan has had a gold and silver currency since the 16th century. The gold coins are large flat pieces in the shape of rectangles with circular corners, the largest size being obans and the smaller kobans; these bear various small official stamps and a large signature in ink of a mint official. They range in length from 6 in. to ½ in. Other gold pieces are the small rectangular pieces of one and two bu issued from time to time; round gold is rare and usually of provincial mints. There have not been many issues of silver, usually in small rectangular pieces; the so-called bean money with the figure of Daikoku, god of wealth, is not a currency but was made to add to the large, long silver presentation pieces to bring them up to a certain weight.

In 1869 a mint on European lines was established in Tokyo, and gold, silver (yen or dollars) and copper have since been regularly issued from it. After World War II the yen was retained as the unit of currency. The e sen of Japan are not coins but amulets and bear figures of Daikoku, Itsibu fishing and others.

6. Korea.—Korea had a bronze coinage of the Chinese style after the 12th century, but it was only with the institution of Shang Ping cash at numerous mints, with an elaborate system of dating or, rather, numbering the issues between 1790 and 1881, that its coinage became common. Attempts were made to establish a silver currency during the years preceding Japanese rule.

7. Vietnam, Cambodia, Laos.—Annam, since the mid-20th century absorbed into the state of Vietnam, began by imitating Chinese coins and had a regular bronze coinage of its own on the Chinese model from the 10th to the 19th centuries. Silver became common in the 19th century in the form of narrow oblong bars. Amulets or, rather, presentation pieces in gold, silver and copper were created in a variety of designs bearing auspicious inscriptions, quotations from the Chinese classics, etc., in addition to the king's name. The native coinage ceased when Annam became a French possession. After independence from France, Vietnam substantially retained the western alphabet on its often very attractive coinage. Separate coinages were in circulation in Cambodia, Laos and North Vietnam.

8. Thailand.—Siam, as Thailand was previously known, down to the middle of the 19th century struck gold and silver in the form of balls formed by doubling in the ends of a short thick bar of silver, and bearing the stamp of the reigning monarch ("bullet" coins). Since *c.* 1860 it has had a coinage on European lines with portraits and issues in gold, silver, copper and, later, nickel, though "bullet" coins circulated until 1909. (J. AL.; S. M. SN.)

X. AFRICA

Ethiopia, which developed a coinage influenced by Arab models in the early Byzantine period, in modern times has long enjoyed the currency of the silver Maria Theresa thalers; but from Menelik II (1889–1913) onward handsome portrait-coins of its emperors have been produced in gold, silver and bronze, with reverses showing the lion of Judah. Eritrea, federated with Ethiopia in 1952, had a fine thaler-size coinage in the late 19th and early 20th centuries. Libyan coinage after 1949 bore a singularly fine portrait of Idris I. The currency of Liberia for over a century has consisted mainly of copper or bronze; the elephant has displaced the head of Liberty. France's widespread dependencies have since World War II showed the French cock, or the head of "Marianne," and often the cross of Lorraine on the reverse. Of Portuguese dependencies Angola has had copper coins since 1814. Coinage for the Congo began with copper in 1887; later issues, some hexagonal, have shown fine elephant designs.

XI. MEDALS AND MEDALLIC ART

Aesthetic and commemorative medals (as distinct from war medals) have a history going back to the classical period. Under the earlier Roman empire, various bronze pieces were struck with special care, bearing specially elaborate types, and not related by weight to the coinage; these (now conventionally termed medallions) were in fact medals, wholly official and imperial in their emphasis. They tended to die out as the habit of precious-metal multiples increased.

In the late 14th century, commemorative pieces appeared, struck for the Carrara family, lords of Padua, in a classicizing style to celebrate the independence of their city. About the same time medals, this time of richest late medieval style, were made, probably as repoussé shells of gold and silver, for the duc de Berry, representing famous Christian rulers of the past.

1. The Renaissance.—Renaissance medals began with the Italian Antonio Pisano, known as Pisanello, born at Verona in the 1390s. First famous as a painter of portraits and animals, he made a portrait medal of the Byzantine emperor John VIII Palaeologus in 1438, followed by a brilliant series for princely and noble persons. All were cast and not struck; they showed a technical perfection allied to a pure naturalism and a genius in composition that gained them universal fame. The fashion of privately commissioned portrait-medals rapidly spread, and among the more famous 15th-century artists were Matteo de' Pasti, Sperandio Savelli, Giovanni Boldù (with a curious leaning to the antique), Francesco Francia, Caradosso Foppa and, a little later, Niccolò Fiorentino and Leone Leoni. This last was in some sense a rival of Benvenuto Cellini, whose medallic work, so far as can be judged, was disappointing, perhaps because (together with Caradosso) he was thinking increasingly of the substitution of mechanically contrived striking for the casting process, which hitherto had given Renaissance medals their superbly sensitive treatment and finish. The Italian medals of the 15th and 16th centuries reveal a common formula—obverse, a portrait; reverse, a device (sometimes pictorial and naturalistic, more often an *impresa,* or badge of devious, riddlelike significance) referring to the person represented on the obverse.

In France the earliest medals were in the medieval late Gothic style; the transition to Italian Renaissance took place at the end of the 15th century: the Lyons medal welcoming Anne of Brittany and Charles VIII, her first husband, in 1494 was fully Gothic, but that for Anne and Louis XII in 1500 was well advanced toward the new naturalism. The principal influences on French medallic art in the 16th century continued to be exerted by Italian artists, including Cellini, who worked for Francis I; but Henry II favoured native talent, employing among others Étienne de Laune, and under Charles IX the emergence of a new, robustly dramatic style may be attributed to Germain Pilon.

Medallic art in the Netherlands had its origin with Italians in the 15th century, but from the 16th century native masters ap-

peared, of whom the painter Quentin Massys (*c.* 1466–1530) was among the first with his fine medal of Erasmus, 1519. The most prolific and technically skilled artist, if not by any means the greatest, was Jacob Jonghelinck (1531–1606), sculptor, engraver, mint-master and goldsmith; Steven van Herwyck was much superior, showing some real affinity with the dominant Italian school.

German Renaissance medals from the first followed an independent tradition. Their emphasis was upon realism in portraiture; the portrait image was very large in relation to the field it occupied, and often strongly featured, heavy, harsh or formidable. The reverses concentrated on complex and sometimes overloaded heraldic designs. In the technique of casting, these works showed high perfection from 1514 onward. The chief centres of activity were Augsburg and Nürnberg, each the home of metalworking and goldsmithery. Among the best-known artists of the 16th century were Hans Schwarz, Friedrich Hagenauer, Christoph Weiditz and Matthes Gebel.

Renaissance medallists had thus shown the brilliant possibilities of profile portraiture on a small scale, not as an imitation of the antique, but as an up-to-date idiom transcending stiff medieval forms. The effect on coinage was of course dramatic, particularly when machinery first began to increase the facilities for the mass production of fine portrait-coins from well-designed, well-cut dies. But the subsequent reverse reaction upon medallic art of the mechanical production of coins was less happy. Although the best medallists throughout the 16th century continued to use the casting process for their most important medals, even when they were also die-engravers by profession, official patronage, requiring number rather than quality, tended to favour the struck medal.

2. The 17th and 18th Centuries.—In the first half of the 17th century France emerged as the finest centre of medallic art, with Guillaume Dupré and Jean and Claude Warin as the supreme exponents of the baroque medal-portrait. Dupré (1574–1647) was both sculptor and metalworker, and his preference was for the cast medal, in which he memorably combined elegance, decorative instinct and technical splendour. Jean Warin (1604–72), no less elegant or accomplished, was perhaps more robust; his output, moreover, was great, and in an age when machinery was taking its place in France he did not hesitate to strike as well as to cast. Claude Warin (d. 1654), less brilliant and less sure, was nevertheless outstanding in the succession of artists who mirrored admirably an age of combined luxury and academic taste. Their influence abroad was strong. In England it was a Frenchman, Nicolas Briot (1580–1646), who infused the coins and medals of Charles I with refinement and delicacy (also, incidentally, pressing on with the introduction of machinery); and the summit of English medallic art, when the skill of the metalworker was still taking the fullest legitimate advantage of the facility given by machinery, was reached by the brothers Abraham and Thomas Simon (*c.* 1622–92, *c.* 1623–65), whose baroque portraits are unsurpassed for brilliance and virtuosity. These developments are the last full flowering of medallic art before it passed into the clever, mechanical mediocrity of the 18th century, exhibiting a taste that was at once international and increasingly routine. Only perhaps in the great papal series of 18th-century medals did some real life survive.

3. The 19th and 20th Centuries.—The academic tradition encouraged in France by the empire and consolidated in England (after the classical Italianate brilliance of Benedetto Pistrucci) by the long reign of Victoria only began to break down after 1870. The French revival took its rise in François Ponscarme (1827–1903). By the extraordinarily sensitive study of character in portraiture, by the search for a dignified realism and for a harmonious relation of type to background and by the freeing of his portraits from the raised border that had for so long enclosed them, he inaugurated a return to the true principles of the art that Pisanello had established. The movement was continued under Jules Chaplain (1839–1909), and its fruits were to be seen even later in the splendid cast medals of the French-trained English artist Theodore Spicer-Simson (1871–1959). Elsewhere the occasional artist of real talent emerged, such as Anton Scharff (1845–1903) in Germany or Alphonse Legros (1837–1911) in England; but in general the use of the reducing machine has continued to tie the artist to his model and make him too careless of its translation into metal. In the first quarter of the 20th century the level of medallic art was everywhere very low, being characterized either by harsh treatment or insipid feeling. In the second quarter the standard rose sharply: not only did portraits increase in number and quality, but the medal borrowed from the plaquette in including purely genre, symbolic and also poetical subjects. More important still, the casting technique began to recover its lost popularity, especially in Italy, where the talent for portraiture and design was strong. In the United States outstanding sculptors have created cast medals, notably David Smith's polemic symbols and Jacques Lipchitz' commemorative roundels. In France casting has been less favoured, but modern French medals exhibit a high degree of poetically complex design and symbolism, as well as a combination of very sensitive portraiture: Josette Coeffin, Raymond Corbin, Henri Dropsy, André Galtié and Georges Lay have all made medals of memorable beauty. Holland has produced I. J. Pieters, and Finland the late Gerda Qvist; in England, beside the native talent of Mary Gillick could be set the contrasting qualities of A. Loewenthal (an expert in preparing models for casting) and P. Vincze. There was no lack of fine and accomplished portraiture, and this, combined with reconsideration of technique and willingness to allow medals to express some poetic or symbolical content, made the mid-20th century a period of experiment in which promise was higher than it had been for a long time past and which required only intelligent patronage to make the fashion for medals thrive again.

XII. PAPER MONEY

The earliest paper currency recorded is apparently that of the T'ang dynasty in China in the 8th century A.D., consisting of receipts for deposits of cash, and Marco Polo's residence in China in the 13th century familiarized him with the monetary notes (printed on mulberry bark paper and sealed in red) of Kublai Khan. Thereafter no paper currency was devised or produced until the Bank of Sweden briefly issued printed notes in 1661, doubtless to ease difficulties caused by coinage based on a cumbrous copper standard. In London a system had already just begun whereby merchants wishing to deposit money with the goldsmiths received a receipt promising to repay; such promissory notes could pass among merchants as currency, though being wholly in manuscript, they were limited in number and thus in circulation. The Bank of England, founded in 1694, at once began to issue promissory notes for "running cash," *i.e.*, such sums as depositors wished to withdraw; the first notes were handwritten, but plans were swiftly made for plate-printed notes (with blank spaces for the payee's name and for the date) for £5 upward.

The fact that these notes could be drawn in favour either of a named person or of "bearer" carried the corollary that they were no longer promissory certificates but, being capable of transference, a form of monetary exchange. Concurrently it became more necessary for an issuing bank to define the prudent balance of "running cash" to be held available for cash demands on presentation of notes, and private banks in the 18th and early 19th centuries that over-issued notes in relation to their cash reserves not infrequently failed, as was the case with John Law's bank in France in 1720. Subsequent practice tended to place the issue of paper money under state scrutiny: in the United Kingdom, for example, the only notes issued are those of the Bank of England, the Royal Bank of Scotland and the Ulster bank, and, although the number of notes issued need not bear an absolutely fixed relationship to British gold reserves, there is always an adequate reserve of other cash behind them. (This is in contrast to 1793 and 1797 when there was a rush to draw out gold, and cash payments had to be suspended in favour of notes.) To this extent notes, although purely token pieces of paper, are based on the strength of the country's economy as a whole.

Sharply distinct from bank-notes are those notes issued in times of necessity. Thus the bills of credit printed by the government of Massachusetts in 1690 originally stood in lieu of hard cash for the colonial troops engaged against the French in Canada; the co-

lapse of the French economy during the French Revolution called forth the assignats (*q.v.;* printed certificates of monetary value to fill the gap caused by the flight and loss of metallic currency); and emergency notes were issued by R. S. Baden-Powell during the siege of Mafeking (1899–1900). Slightly different was the "Bradbury" issue of notes (5*s.*, 10*s.* and £1) undertaken by the British treasury (over the signature of Sir John Bradbury, its permanent secretary) to stabilize the British currency system in and after 1914 when gold was withdrawn from circulation: in this emergency measure, the treasury assumed a responsibility that the Bank of England could not at immediate notice discharge.

The economic dangers arising from the temptation to print too many notes in relation to genuine monetary reserves, *i.e.*, to reduce paper money to a wholly token status, are well shown by the unhappy history of Confederate currency in the United States (in 1864 its value was estimated at only 10% of its face-value in gold) or by the inflation of the German mark after World War I, when, with each successive decline in value, notes were printed of ever growing face-value, until total collapse was reached with the issue of notes individually to the value of millions of marks.

Because notes are generally large enough to bear on their face a considerable amount of information, *e.g.*, issuing authority, value and date, they can also declare the territorial limits of their validity. Paper money has thus often been used for "closed-economy" groups or communities, such as an army-group in a particular theatre of war or an internment camp. Such official vouchers were the notes issued by the British economist Robert Owen in the early 19th century on behalf of the National Equitable labour exchange: these directed the store-keeper of the exchange to deliver goods worth from 10 minutes' to 80 or more hours' work, on the assumption that all men work equally hard and that value can thus be measured evenly in terms of time-output.

With the greatly increased use of paper money its physical design radically changed, not least as a guard against forgery. Paper, originally suitable for manuscript insertions, was specially made and became both tougher and smoother. Printing, originally in black upon plain white from an engraved plate, later called for the fullest skill of engravers and polychrome printers. With the disappearance of gold from the world's currencies paper money was assured of a long future, and, although many countries were disinclined to produce notes of less than the equivalent of about a dollar, the use of paper for higher sums (particularly after the inflation caused by World War II) became usual. (C. H. V. S.)

U.S. Paper Currency.—The continental congress and the individual states fared poorly with their paper emissions before, during and after the Revolution, and the federal government issued no paper money (except a few promissory notes, all long since redeemed) until the Civil War. Nevertheless, most states authorized banks to utter paper money to the amount of their gold reserves. With inadequate supervision, abuses developed; most banks inflated their notes, that is, they issued more than their gold assets could cover, in the hope that not too many people would demand redemption in specie. Many banks failed in 1860–62 when their creditors demanded gold in quantity for their paper money and when their debtors in turn defaulted on payments to the banks. Despite the resulting financial hardship, even larger issues of inflated paper currency followed; it is reliably estimated that, exclusive of the Confederate treasury and Southern state notes, over 3,500 varieties were in circulation up to 1862.

To help finance the Civil War, congress suspended specie payments and uttered some $60,000,000 in paper money in 1861, and larger amounts thereafter, proclaiming them legal tender although they were unredeemable in anything until 1879. From 1863 to 1876, as a substitute for jealously hoarded coins, the government printed nearly $369,000,000 in fractional currency, each bill being less than a dollar in value. The shortage of coins was so acute that postage stamps were being used as a medium of exchange, and the earliest regular fractional notes depicted stamps, the 25-cent note bearing five reproductions of the five-cent stamp, for example. After 1875, fractional notes were redeemed in silver.

Beginning in 1878 the government issued silver certificates backed by, and redeemable in, the silver dollars that were starting to accumulate in treasury vaults. Congress from 1863 to 1933 authorized many banks to issue notes backed by funds deposited in Washington, D.C., for the purpose, but the majority of these notes have been recalled. At irregular intervals from 1865 to 1922 the Treasury emitted gold certificates, but these were recalled in 1934. After 1914 the federal reserve banks issued fully secured notes. The cost of the special paper used for currency occasioned the reduction in note size in 1929. After 1933 U.S. paper money thus mostly comprised uniform silver certificates and federal reserve notes. Silver certificates are no longer being issued.

Sutherland in *Journal of the Royal Society of Arts*, 1955. *Periodicals: Aréthuse* (1923–31), *Médailles* (1938–). (C. H. V. S.; S. M. Sn.)

NUMMULITE, any of the thousands of extinct species of foraminiferan protozoa whose shells are often indicators of oil-bearing rock. See FORAMINIFERA.

NUN, a member of an order or congregation of women, living a life of religious observance under vows of poverty, chastity and obedience. In Roman Catholic canon law only women living under solemn vows are nuns (*moniales*); those under simple vows are properly called sisters (*sorores*). Widows and penitents, by dispensation, are received into all orders except the Carthusian, which requires complete bodily integrity. See MONASTICISM; WOMEN'S RELIGIOUS ORDERS.

NUNATAK, a hill or mountain peak appearing above the surface of a glacier. Greenland is for the most part covered by an icecap which moves slowly downward to the sea. It will rise upward and pass over a barrier if there is no outlet, but will flow between and around mountain peaks leaving them standing as hills (nunataks) above the general surface of the icecap. There are also nunataks in Antarctica but they are less numerous and more widely scattered. The term is an Eskimo loanword.

NUNC DIMITTIS, the canticle in the Bible also known as the Song of Simeon, beginning "Lord, now lettest thou thy servant depart . . ." (Lat. *Nunc dimittis servum tuum, domine*. . .). It was uttered by the aged Simeon when the Virgin Mary brought the infant Jesus to the Temple to be presented to God (Luke ii, 29–32). Since at least as early as the 4th century the Song of Simeon has formed part of the church's evening worship; it contains a reference to Christ's salvation as the light of the gentiles, which makes it appropriate for use when the church relies on the divine light through the hours of darkness. It is part of vespers in the Orthodox *Euchologion*, of compline in the Roman breviary and of evensong in Anglican prayerbooks. At the end of the liturgy of St. John Chrysostom it is repeated by the priest as he takes off his stole.

NUNCIO, the resident representative of the pope in major countries, diplomatically accredited to the government (since the congress of Vienna, dean in some countries of the diplomatic corps), and also endowed with certain papal rights of jurisdiction over the Catholic faithful. The office is historically related to that of the apocrisiary at the Byzantine and Frankish courts (5th and 6th centuries) and to that of later papal fiscal officials. Angelo Leonini, sent to Venice in 1500, is usually regarded as the first official nuncio. A nuncio differs from a legate, whose office is temporary. Internuncio is the title used in some countries of nonambassadorial status. Apostolic delegate (equivalent to minister plenipotentiary) is the title used in some countries. An apostolic delegate differs from a nuncio in that he lacks diplomatic status.

See also LEGATE; VATICAN. (J. C. MY.)

NUNEATON, a municipal borough (1907) in the Nuneaton parliamentary division of Warwickshire, Eng., on the Anker river and the Coventry canal, 19 mi. N.N.E. of Warwick. Pop. (1961) 57,376. The prefix "Nun" was added to its name when a Benedictine nunnery was founded there between 1155 and 1159. Situated near a coalfield and granite quarries, Nuneaton has large engineering and brick works and a flourishing textile industry. Other trades are leather dressing, boxmaking, fellmongering and the manufacture of needles. In 1819 Mary Anne Evans, who wrote under the name of George Eliot, was born at Chilvers Coton, Arbury, now within the borough.

NUNES, PEDRO (PETRUS NONIUS) (1492–1577), Portuguese mathematician and geographer, the peak figure in Portuguese nautical science, was born at Alcacer do Sal in 1492. He was professor of mathematics at Lisbon and Coimbra, and was made royal cosmographer in 1529 when Spain was disputing the position of the Spice Islands and maps did not agree in their longitude. He devoted himself to such problems, to maps and map projections. He was the first to show that a loxodrome course gives a spiral route, and published studies of the sphere and of the oceans. In 1538 he went to Spain, but returned to Portugal in 1544, when he was the best informed man in the world on the new discoveries of Spain and Portugal. He died at Coimbra in 1577.

See A. Cortesao, *Cartografia e Cartografos Portugueses*, 2 vol. (1935). (A. DS.)

NÚÑEZ, RAFAEL (1825–1894), leading Colombian political figure of the late 19th century, was born Sept. 28, 1825, in Cartagena. He entered politics in the Liberal party while in law school, and moved to the national political scene in 1853. Holder of many high government offices, pre-eminent political figure from 1880, three times president of Colombia (1880–82, 1884–86, 1886–92), he was leader of the independent faction of Liberals. A Radical Liberal rebellion in 1884 forced Núñez into alliance with the Conservatives and enabled him to institute a series of reforms called the Regeneration, including the concordat of 1888 ending religious conflict (1850–85) and the existing centralized constitution of 1886 terminating federalist anarchy (1858–86). Regarded as the leading intellect of his time, an active publicist and journalist, Núñez wrote on politics and economic policy and composed volumes of poetry. Domineering, able, opportunistic, he was during his public career on both sides of every national controversy. He died in El Cabrero, on Sept. 12, 1894. (R. L. GE.)

NÚÑEZ CABEZA DE VACA, ALVAR (*c.* 1490–*c.* 1560), Spanish explorer, was treasurer of the ill-fated expedition of Pánfilo de Narváez to Florida in 1527–28. Of 300 men who disembarked, only four, including Cabeza de Vaca, ever returned to civilization. For eight years they wandered among the Indians

of the Gulf coast and northern Mexico though their exact route has long been debated. Cabeza de Vaca's adventures (which he related upon his return) probably led to the De Soto expedition of 1538, and without question inspired the Coronado enterprise of 1540, both of which probed deeply into areas which later formed part of the United States.

Returning to Spain to seek recompense for his services, he was appointed governor of the province of Rio de la Plata. He reached Brazil in March 1541, and from November of that year to March 1542, he traveled 1,000 mi. to Asunción, the provincial capital. Intrigue and rebellion led by Domingo Martínez de Irala resulted in his seizure, confinement and (in 1545) deportation to Spain. The council of the Indies, finding him guilty of malfeasance in office, sentenced him to banishment from the Indies and to military service in Africa. Upon his appeal, the council reduced the sentence but never reversed the judgment. Cabeza de Vaca died in obscurity and poverty.

See Morris Bishop, *The Odyssey of Cabeza de Vaca* (1933); for sources, Cabeza de Vaca, "The Narrative" in *Spanish Explorers in the Southern United States* (1907). (K. M. S.)

NÚÑEZ DE ARCE, GASPAR (1832–1903), Spanish poet and statesman, once regarded as the great poet of doubt and disillusionment, though his rhetoric is no longer found moving. He was born in Valladolid on Aug. 4, 1832, became a journalist and Liberal deputy, took part in the 1868 revolution and was colonial minister for a time after the Restoration. He died in Madrid on June 9, 1903. As a dramatist he had some success, his best play being the historical *El haz de leña* (1872), but he attained celebrity with *Gritos del combate* (1875). This volume of verse sought to give poetic utterance to religious questionings and the current political problems of freedom and order. His longer poems include *Última lamentación de Lord Byron* (1879); the allegorical *La selva oscura* (1879); a study of Luther, *La visión de Fray Martín* (1880); and the sentimental narratives *La pesca* (1884) and *Maruja* (1886). (H. B. Hl.)

NUORO, a province of central Sardinia, created in 1927 out of parts of Cagliari and Sassari provinces; it had been a province under Piedmontese rule from 1848 to 1860. Pop. (1961) 265,750; area 2,808 sq.mi. The headquarters town is Nuoro, lying on an east-west road linked with the east coast road and the western north-south highway. It was first recorded (as Nugorus) in the 12th century; the site was inhabited from remote antiquity. The province consists essentially of the highland backbone of Sardinia, including the massifs of Gennargentu, Albo, Monte Ferru and Catena del Marghine. It is the poorest region of the island, occupied largely by pastoralists, but after 1950 developments included 30 mi. of new road, improvement of more than 17,500 ha. of mountain pastures (Argosolo, Mamoiada, Fonni) and the grafting of 2,000,000 wild olive trees (Siniscola, Posada, Torpè). (J. M. Ho.)

NUPE. This Islamized kingdom in the heart of Nigeria (*q.v.*) lies at the confluence of the Niger and Kaduna rivers. About 360,000 people in the 1960s, they speak five main dialects of the Nupe language, which belongs to the Kwa language group (*see* African Languages). They are organized into a number of closely related subtribes, of which the Beni, the Zam, the Bataci (Batache) and the Kyedye (Kede) are the most important, although a dozen others can be named. The Kyedye and Bataci are river people, subsisting primarily by fishing and trading, while the other Nupe are primarily farmers, the staple crops being millet, sorghum and yams. There is a highly developed guild organization for craftsmen who specialize as blacksmiths, brass-smiths, weavers, beadworkers, glassmakers, tailors, matmakers, barbers and drummers. Either men or women may be specialist traders.

Nupe live in grass-thatched huts of mud brick built in villages or towns varying in size from a few families to towns such as Bida, Kutigi and Mokwa with populations of several thousand people. Villages were formerly surrounded by a wall, but today walls are seldom encountered. Indigenously the Nupe kingdom was divided into four zones for purposes of government, with a series of ranked officials who owed a feudallike allegiance to the king, called Etsu Nupe. The Beni and the Kyedye both are organized as kingdoms within the greater Nupe kingdom, their kings also owing fealty to the Etsu Nupe. The population is divided into nobility, commoners and clients. The office of Etsu Nupe rotates among three noble families.

Nupe are polygynous, and bridewealth (*q.v.*) changes hands at most marriages. The majority are now Muslim, but many pagan rituals are still performed. They are noted throughout Nigeria for glass beads, fine leather and matwork, as well as brass trays and fine cloth.

NUREDDIN (Arab. Nur al-Din, "Light of the Faith"; Abu'l Qasim Mahmud) (1118–1174), a Muslim leader in Syria who by his achievements against the crusaders laid the foundations for the later triumph of Saladin (*q.v.*), was born in Feb. 1118. Succeeding his father, Zangi (*q.v.*), as ruler (atabeg) of Halab (Aleppo) in 1146, he speedily recaptured Edessa, which had been temporarily lost to the crusaders after his father's death. Apart from waging direct military campaigns against the crusaders Nureddin pursued a policy of the unification of the Muslim forces under his authority. After annexing Damascus (1154), he succeeded in submitting Egypt to his control (1168). As a result of this achievement Saladin, who participated in the conquest of Egypt, emerged as a powerful military commander. At the time of his death Nureddin's authority was recognized in Syria, Egypt and in parts of Iraq and Asia Minor.

Nureddin was a strict Muslim whose whole life was dedicated to the cause of Islam. Thus, while organizing the military effort of his kingdom, he also supported the religious and cultural activities of his subjects. He built many new mosques, schools, hospitals and caravanseries. But the greatest services were rendered by him in the struggle against the "infidels." His successes contributed to the popularity of the holy war against the crusaders and resulted in many defeats of the Christian enemy. His accomplishment in the field of the unification of Muslim forces proved to be fundamental for the subsequent victory of Saladin. Nureddin died at Damascus on May 15, 1174.

For a discussion of Arabic and western sources *see* C. Cahen, *La Syrie du nord à l'époque des Croisades* (1940). For a modern account of Nureddin's career *see* S. Runciman, *History of the Crusades*, vol. ii (1951); H. A. R. Gibb, "The Career of Nūrad-Dīn," in *A History of the Crusades*, vol. i, pp. 513–527 (1958). (A. S. Eh.)

NURHACHI (1559–1626), a tribal chieftain in Manchuria who organized an army of mounted archers during the 1590s and established military and political control over all of Manchuria. In the year 1616 he proclaimed himself emperor of China and was thus a forerunner of the Manchu or Ch'ing dynasty (1644–1912). He defeated a large Chinese army and captured several border cities but died before he was able to invade China.

See Ch'ing; Manchus; China: *History*.

NURI AS-SAID (Nuri al-Sa'id Pasha) (1888–1958), outstanding Iraqi statesman, was born in Baghdad in 1888, educated there and in Istanbul, and was commissioned in the Turkish army in 1909. He married, in 1910, the sister of Ja'far Pasha al 'Askari (*q.v.*). He saw service during 1912–13 against the Bulgarians. Thereafter, in Istanbul and later, during 1913–14, in Cairo and Basra, he became increasingly involved in Arab secret societies which envisaged home rule. In 1916, after a year's *résidence forcée* in India, he was helped by the British to join the (anti-Turkish) Arab revolt in the Hejaz, and reached Jidda in July. Thereafter for 26 months Nuri was a vigorous, competent, gallant and dynamic figure in the Arab army of Amir Faisal, to whom he came to stand in the closest personal relationship. He acted as staff officer, adviser and devoted supporter throughout the amir's rule in Syria (1920), and accompanied him to Versailles and on many journeys. When the Syrian kingship was lost, Nuri followed Faisal to his elected throne in Iraq (Aug. 1921). With integrity, ready accessibility and the highest contacts in neighbouring countries and in Europe, for the following 37 years he played a unique part in Iraqi constitutional, political and administrative life and was 14 times prime minister between 1930 and

1958. Standing for the monarchy and for a cordial relationship with Great Britain (not least in the critical mid-war period, 1940–41), the pasha suppressed extremism, Communism and the more effervescent forms of politics at home, opposed Zionism, and improved relations with Turkey and Iran. In wider Arab circles, in which by 1935 he had achieved a unique status, he urged all practicable forms of Arab unity and was an inspirer or founder of the Arab league (1945). Later, as pro-western creator of the Baghdad pact (1955), he lost popularity, and his somewhat autocratic regime at home offended the underemployed Iraqi intelligentsia. He was murdered in Baghdad during the military revolutionary *coup*, on July 16, 1958. *See* also IRAQ: *History*.

See Lord Birdwood, *Nuri as-Said* (1959); S. H. Longrigg, *Iraq 1900 to 1950* (1953). (S. H. Lo.)

NURISTAN (KAFIRISTAN), a region of eastern Afghanistan forming the northern part of the province of Nangrahar. Its area is approximately 5,000 sq.mi. and the population about 50,000. It comprises the upper parts of the three large north-south valleys of the Alinghar, Peech (Parun) and Bashgal. Its northern border follows the main range of the Hindu Kush, and on the east it is bounded by West Pakistan, west by the mountain ranges above the Nejrab and Panjshir valleys and southeast by the Kunar valley. Kafiristan ("land of the Kafirs," *i.e.*, infidels) came under Afghan rule in 1895 and after the forcible conversion of its people to Islam it was renamed Nuristan ("land of light or the enlightened").

The region is mountainous, forested and relatively rainy. The highest lying forests are dominated by conifers (deodar, pines) which grow from below 7,000 ft. to above 10,000 ft. Below 7,000 ft., mixed deciduous forest is prevalent with oak, maple, hawthorn and walnut. Below 5,000 ft. the deciduous forest becomes almost universal. The Asmar forest to the east produces a large part of Afghanistan's timber.

The people speak various Kafir languages (*see* DARDIC LANGUAGES) which are of unknown but very old Indo-European origin. They are light-skinned, of medium height, hardy and brave. Their record was one of pagan superstition, brigandage and plundering; they were, and still are, intensely loyal to their own people and strongly cherish their independence. They have a clan organization with village government, and are now settled agriculturists. The region as a whole has a most distinctive culture, and although it is possible to establish certain cultural differences between the three main valleys, yet they share a culture which gives them a unique position within Afghanistan.

The houses in the highest northern regions are built of stone or clay, but in the forested regions mainly of wood, and often (to save space) in several stories, stepwise above each other. They often have verandas and are richly carved. The small enclosed fields (often no bigger than an ordinary floor space), mostly lying in steep, narrow mountain valleys, are cultivated by the women, while the men hunt or tend livestock. The soil has to be fertilized and is sometimes irrigated by water brought for miles in wooden conduits along the mountainsides. Water mills for grinding grain are common. The usual Afghan wooden plow is used wherever possible, but is drawn by only one ox. The main crop is wheat, with barley, maize (corn), millet and peas. Grapes and mulberries are grown in the lower parts, and fruits are gathered—pomegranates, *Zizyphus* berries, blackberries and the fruits of conifers. Livestock consists mainly of goats, with some cattle, and a few sheep in the upper, wider valleys. There are no horses.

The whole of this recessive, very characteristic civilization is still partly preserved and marked by the strong geographical isolation and the paganism which prevailed until the 1890s, according to the descriptions of Sir George Scott Robertson, who visited Kafiristan at that time, and the Russian, Danish (1947–64) and German travelers who described it up to the mid-20th century. *See* also NANGRAHAR; AFGHANISTAN: *The People*.

See Sir G. S. Robertson, *Kafirs of the Hindu-Kush* (1896). (J. P. C. N. H.)

NÜRNBERG (NUREMBERG), the second largest town (pop. [1961] 454,520) in the *Land* (state) of Bavaria, which following the partition of the nation after World War II became part of the Federal Republic of Germany, and also administrative centre of the province of Mittelfranken (Middle Franconia), is situated on a sandy plain at the foot of the Franconian Jura, on both banks of the Pegnitz river 147 km. (92 mi.) N.N.W. of Munich. The Pegnitz flows into the Regnitz at the town of Fürth, 6 mi. to the northwest, and the Regnitz joins the Main at Bamberg (so connecting Nürnberg with the Rhine valley) and also makes possible communication eastward with Czechoslovakia. Nürnberg's wealth as a trading centre in the 12th and 13th centuries was devoted to building and to patronage of the arts. Its industrialization in the 19th century and its use as a war-production centre by the Nazis led to severe bombing during World War II. It was, however, reconstructed according to the original ground plan, and many of its damaged buildings were carefully restored. Its importance as a commercial and industrial centre has not destroyed its medieval character.

The older, central part of the city, the Altstadt, is still enclosed by the medieval walls (completed 1452), with their 128 towers and four main gates. It is divided by the Pegnitz river into the Lorenzer Seite (named after the Gothic St. Lorenzkirche) on the south and the older Sebalder Seite (named after the Romanesque-Gothic St. Sebalduskirche) on the north. The Sebalder Seite slopes up to the red sandstone castle rock on the northwest from which the gray-walled castle, with its five-cornered 11th-century tower and 12th–16th-century Kaiserburg (imperial castle), dominates the town. Just below is a perfectly preserved medieval square, near which is Albrecht Dürer's house (*c.* 1450, where he lived and died [1509–28]). St. Sebalduskirche (1225–73; east choir 1361–79) contains a magnificent bronze shrine by Peter Vischer and his sons Peter and Hermann (1508–19). Also on the Sebalder Seite are the Marktplatz, where stands the 14th-century Schöner Brunnen and the Gothic Frauenkirche (Church of Our Lady, 1352–61) on the west front of which is the Männleinlaufen, a mechanical clock made about 1509 to commemorate the Golden Bull of 1356, showing the seven electors moving round Charles IV; the gabled Fembohaus (1591–1600), the only surviving example of a burgher's house, which is now the old town's historical museum (founded 1953); and the Heiliggeistspital or Hospital of the Holy Ghost (founded 1331, expanded 1487–1527).

The two halves of the town are connected by the Königstrasse, a busy street containing modern shops as well as old buildings. It leads up to the St. Lorenzkirche (*c.* 1260–1360; choir 1439–77), containing the famous "Engelsgruss" (Annunciation) carved out of linden wood by Veit Stoss (1517–18), the stone sanctuary by Adam Kraft (1493–96) and an ornate rose window over the west door (1350–60). Also in the Königstrasse are the gabled market hall (built as the city granary, *c.* 1500) and the small churches of St. Klara (Gothic; choir 1273) and St. Martha (1360).

Among modern buildings worthy of mention (many built or rebuilt after World War II) are the school of economics and sociology, the school of music and the academy of art. The Germanic National museum (founded 1852) contains exhibits illustrating German art and culture from prehistoric times to the early 19th century. There are an industrial institute, a transport museum and an excellent municipal library, containing 3,000 manuscripts and 2,000 incunabula, in a modern building on the city's outskirts.

To the southeast of the city is Dutzendteich, which was used by the Nazis for their annual September rallies (1933–38). Some of its buildings have been dismantled. There is also a sports stadium (1923–28), and a national park on the slopes of the Schmausenbuck (1,276 ft.).

Nürnberg is an important south German railway junction, although the division of Germany after World War II severed many of its connections; *e.g.*, Halle-Leipzig-Berlin, Hof-Dresden-Warsaw, Eger-Prague. Nürnberg is on the Munich-Berlin *Autobahn* and the *Autobahn* to Frankfurt am Main, constructed in the 1960s, connects it to the Rhineland. The construction of the planned Rhine-Main-Danube canal would greatly aid its economy. An airport was opened to the north of the town in 1955.

Nürnberg is the centre of the great north Bavarian economic region. Its chief industries, in order of importance, are iron and metal production and manufacture, manufacture of business ma-

chines, cables, electrodes, telecommunications equipment, machinery and motor vehicles. Also characteristic are the toy industry (International Toy fair); the manufacture of gingerbread, chocolate, margarine and pharmaceutical goods; and brewing. Nürnberg is also important as a market for the export of Bavarian hops.

History.—Founded about 1040 as a stronghold by Henry III, duke of Bavaria and emperor of Germany, Nürnberg developed rapidly as a community of traders and artisans clustered around the castle. Destroyed in 1127, it was rapidly rebuilt, and in 1140–50 spread from the north to the south bank of the river. Its popularity with pilgrims because of miracles attributed to the tomb of St. Sebald, its position as a trading centre on the important trade route linking Germany with the Mediterranean and the patronage of the emperors caused it to flourish in the 12th and 13th centuries. In 1219 it received its great charter from Frederick II and after the middle of the century became a free imperial city, owning considerable land and ruled by a council of 42, most of whom belonged to wealthy patrician families. Alongside the development of wealth and influence went the development of learning and of crafts of all kinds. The names of the artists Michael Wohlgemuth and Albrecht Dürer, the sculptors Adam Kraft and Veit Stoss, the bronze founder Peter Vischer and his sons, and the scholars Martin Behaim, Johann Müller (Regiomontanus) and Willibald Pirkheimer testify to the quality of the city's artistic and academic life in the 16th century. The *Gymnasium Aegidianum*, founded in 1526 by Philipp Melanchthon, was among the first in Germany. The city also achieved fame as the nursery of German *Meistergesang* and home of Hans Sachs (*see* MEISTERSINGER). It was in Nürnberg that Peter Henlein invented (1500) the mainspring and possibly the first pocket watch, the "Nürnberg egg"; J. C. Denner invented the clarinet there in the early 18th century. In 1525 it was the first imperial city to adhere to the Reformation.

As a result of the change of direction of the great European trade routes after the discovery of the Americas and of the sea route to India, of the devastation of the Thirty Years' War during which Gustavus II Adolphus was besieged there, and of the customs policy of the great powers in the 17th century, Nürnberg gradually declined in importance. In 1806 the town and its lands were absorbed into the kingdom of Bavaria. The first German railway, the Ludwigs-Eisenbahn (1835–1922), ran from Nürnberg, and the city's industrialization in the 19th century gradually reestablished its position. In the 1930s it became a centre of the National Socialist party; in 1935 it gave its name to the anti-Semitic Nürnberg decrees. It was severely damaged in air raids in Jan.–Feb. 1945; 6,716 people lost their lives. It was captured by U.S. troops and was the scene of the Allied trials of German war criminals (*see* WAR CRIMES).

NURSERY: *see* ARBORICULTURE.

NURSERY AND COUNTING-OUT RHYMES. A nursery rhyme may be understood to be any verse that is customarily said or sung to small children. From the point of view of definition, the source and age of the rhyme is immaterial, and it need not originally have been intended for children. It becomes a nursery rhyme through usage. It happens, however, that when a child has to be entertained, the rhymes and songs most readily recalled are those from an adult's own childhood, and this is the reason why the nursery repertoire remains moderately stable. Nevertheless a rhyme or song which was new when the adult was a child may occasionally come to mind along with the old verses, and thus enter the stream of tradition. It follows that the ages of nursery rhymes vary considerably, and the origin and history of each rhyme must be examined individually.

Some of the oldest rhymes are probably those which accompany simple babies' games, such as "Handy dandy prickly prandy, which hand will you have?" (recorded 1598), and the face-tapping formula "Brow bender, eye peeper, nose dropper, mouth eater, chin chopper" (recorded 1788). These formulas were almost certainly old when they were first recorded, as is shown by the existence of parallel formulas on the continent of Europe. For instance the German "Windle, wandle, in welchem Handle, oben oder unt" and "Kinnewippchen, Rotlippchen, Nuppelnäschen, Augenbräunchen, Zupp-Zupp-Härichen."

In a few cases—for example the verse addressed to the ladybird

> Ladybird, ladybird, fly away home,
> Your house is on fire and your children all gone;

the singing-game "London Bridge is falling down"; and the riddle rhyme popularized by Lewis Carroll, in *Through the Looking-Glass* (1872), "Humpty Dumpty sat on a wall"—numerous parallels are to be found half across Europe. The likelihood of direct translation can be discounted, and it is possible that these rhymes have come down from very early times. The ancient practice of incarcerating a human being in the foundations of a new bridge to serve as a guardian spirit may lie behind the stanza of "London Bridge is broken down" which begins "Set a man to watch all night." The watchman was thought necessary to overcome the supernatural opposition which kept destroying the bridge.

Counting-Out Rhymes.—Another type of rhyme which has European equivalents is the gibberish counting-out formula employed by children in their games to determine which one of them shall take some special role. The similarity of the sound of formulas repeated by children in different countries is sometimes remarkable. In Great Britain children may say:

> Eena, meena, mona, my,
> Barcelona, bona, stry,
> Air, ware, frum, dy,
> Araca, baraca, wee, wo, wack.

And in northern Germany:

> Ene, tene, mone, mei,
> Pastor, lone, bone, strei,
> Ene, fune, berke, berke,
> Wer? Wie? Wo? Was?

The refrain "Eena, meena, mina, mo" can also be compared (as can the refrain "Hickory, dickory, dock") with certain sets of numerals, reaching to 20, which have long been used in England by country folk in their work, for instance by shepherds counting their sheep and fishermen assessing their catch. An example from Yarmouth begins: "Ina, mina, tethera, methera, pin, sithera, lithera, cothra, hothra, dic." The origin of these scores is uncertain; they may be Celtic or Danish survivals, but there can be little doubt that when schoolchildren indulge in "Chinese counting" as they call it in England, or "Indian counting," as they call it in the United States, they are preserving, even if in a corrupted form, the sounds of very ancient numerals.

Sources.—Such relics of the far past are exceptional. The majority of nursery rhymes date back only to the 16th, 17th or more frequently, to the 18th century. Almost all of them appear to have been deliberate compositions rather than to have evolved over a course of years, and to have been primarily intended for adult entertainment. A number of them seem to have been popular ballads or songs. The original version of "The frog who would a-wooing go" was entered in the Stationers' Register as *A most Strange weddinge of the frogge and the mowse* in 1580. "Nose, nose, jolly red nose," which still flaunts its bacchanalian associations, was featured in *The Knight of the Burning Pestle* by Beaumont and Fletcher in 1607. A version of "Three blind mice" was printed, with tune, in Thomas Ravenscroft's *Deuteromelia* (1609). A verse of "There were three jovial Welshmen" appeared as "There were three men of Gotam" on a broadside of 1632, and may earlier have been known to Shakespeare (*The Two Noble Kinsmen* [1613], Act III, sc. v). "Lavender's green, diddle, diddle, lavender's blue" appeared on a broadside printed between 1672 and 1685. More recently, "If I had a donkey wot wouldn't go" was written by Jacob Beuler about 1822. "Oh where, or where has mine little dog gone?" was written in 1864 by Septimus Winner, and another song of his is still repeated in American nurseries:

> Ten little Injuns standin' in a line,
> One toddled home and then there were nine. . .

From this came the diminishing "Ten little nigger boys" of the

English nursery, written by Frank Green in 1869 for performance by the Christy minstrels.

There is no reason to think that many of these songs have a hidden significance, any more than have the popular songs of the present day. Some, naturally enough, were inspired by personalities of the time, and occasionally these can be identified. The original Elsie Marley who "is grown so fine, She won't get up to feed the swine" was almost certainly an attractive alewife living in county Durham in the 18th century; and "The brave old Duke of York" probably slanders Frederick, son of George III. Many political lampoons were brief doggerel verses, such as "Hector Protector was dressed all in green," "Little General Monk sat upon a trunk" and "William and Mary, George and Anne" (the daughters and sons-in-law of James II). "Jack Sprat could eat no fat" appears (at latest in 1659) to have been used to ridicule an Archdeacon Pratt, and local tradition in Somerset associates "Little Jack Horner" (recorded 1725) with a Thomas Horner of Mells who did well for himself during the dissolution of the monasteries.

Collections.—The earliest known collection of nursery rhymes, *Tommy Thumb's* (*Pretty*) *Song Book*, was published in London in two small volumes in 1744. Only a single copy of the second volume has survived, but it contains 39 rhymes including "Little Tom Tucker," "Bah, Bah, a black Sheep," "There was a little Man, and he had a little Gun," "Sing a Song of Sixpence," and "Who did kill Cock Robin?" The most influential collection in the 18th century was *Mother Goose's Melody: or, Sonnets for the Cradle*, printed *c.* 1780, but probably compiled earlier. This collection of 51 rhymes, including "Jack and Jill," "Ding dong bell," and "Hush-a-by baby on the tree top," was reprinted by Isaiah Thomas of Worcester, Mass., *c.* 1785, and it seems to be through this collection that the rhymes are frequently thought of as belonging to "Mother Goose." The name "Mother Goose" had been taken from *Mother Goose's Tales*, the familiar title of Charles Perrault's collection of fairy tales which had been translated into English in 1729. There is no verifiable evidence and little likelihood that a book called *Songs for the Nursery; or Mother Goose's Melodies for Children* was printed in Boston, Mass., in 1719; and the association of this legendary collection with one Elizabeth Goose (1665–1757) is merely delightful hey-diddle-diddle.

NURSERY SCHOOL: *see* DAY NURSERY; PRE-ELEMENTARY EDUCATION.

NURSING as a profession is of comparatively recent origin, but the art of nursing in the form of nurturing the young, protecting the helpless and tending the sick and injured is at least as old as recorded history. The evolution of nursing in different countries has been extremely uneven. Historically, its development falls into four loosely defined periods: pre-Florence Nightingale, up to 1860; the pioneer Nightingale period, 1860 to about 1900; the period of expansion and professional organization, *c.* 1900–19; and the period of improved methods of nursing education, government recognition and growing international relationships, from about 1919 onward.

Before the Christian era, nurses, or attendants, are mentioned in the early medical records of China, India, Greece and Rome, but no reliable data about them exist. From the earliest Christian times nursing was regarded as a paramount duty of the church and with the rise of monasticism the care of the sick became the function of many religious orders of men and women. Among the earliest nursing records are those of the *hôtel Dieu* in Paris (early 7th century) and of the *hôtel Dieu* in Lyons (6th century). The military nursing orders, notably the Knights Hospitallers of St. John of Jerusalem (*c.* 1100), established well-equipped hospitals under rigorous quasi-military discipline. Many later nursing orders were important, *e.g.*, the Brothers of St. John of God in the 16th century and the world-famous Sisters of Charity, founded by St. Vincent de Paul, whose work began in 1633 under Mlle Le Gras (St. Louise de Marillac) and whose rule was confirmed in 1645.

The Reformation, with the suppression of monastic hospitals, left England without a system of hospital nursing and consequently nursing had no distinctive part in the colonial development of the United States. Hospitals built by the Spaniards in Latin America antedated those in the U.S. by about 300 years. The Jesuit missionaries in "New France" sent "relations," *i.e.*, reports, which aroused interest in France as to the needs of Canada's colonists. The first nursing sisters to cross the Atlantic ocean, in 1639, were Augustinians from Dieppe; they were established at the Quebec *hôtel Dieu* in 1658. Jeanne Mance (1606–73), the first white woman to arrive in Montreal, founded the *hôtel Dieu* there in 1644, assisted by nursing sisters of the order of St. Joseph de la Flèche, while herself remaining a lay woman. During the 18th century there was little development in Canada or elsewhere although Mme Marguerite d'Youville organized the Soeurs Grises at Montreal in 1755, and the Charity hospital, New Orleans, was staffed by Ursuline sisters from 1737 until Louisiana was purchased by the U.S. in 1803.

The early 19th century heralded the beginning of several nursing reforms. In Ireland, Catherine McAuley (1787–1841) started the Sisters of Mercy in 1831 and Mary Aikenhead (1787–1858) began the work of the Irish Sisters of Charity in 1834. In England two nursing sisterhoods of the Church of England, the Devonport sisters and St. John's House, began work in 1848; St. John's House undertook the nursing in King's College hospital in 1856 and later in several other London hospitals. In 1836 Pastor Theodor Fliedner and his wife established at Kaiserswerth, Ger., an institute for deaconesses in whose training nursing was included. At Lausanne, Switz., an independent school of nursing was opened, in 1859, in order to give young women theoretical and practical instruction in nursing. This school, La Source, was still active in the 1960s.

UNITED KINGDOM

The Birth of Modern Nursing.—Florence Nightingale (*q.v.*, 1820–1910) made outstanding contributions to the development of sanitation, medical statistics, military medicine and hospital administration, but she is best known as the founder of modern nursing. Although born to luxury and wealth, she was from her youth dissatisfied with a life of leisure. The administration of hospitals and the provision of proper nursing became her main interest. She visited several hospitals in Europe and in 1851 spent three months at the Deaconess institute at Kaiserswerth. In 1853 Miss Nightingale took charge of a small London hospital for gentlewomen, but a year later she undertook, at the request of the secretary at war, Sidney Herbert, the organizing and leading of a band of nurses for the British army hospitals in the Crimean War. This most difficult task was brilliantly accomplished and she returned to England a national heroine.

With a fund raised in her honour by public subscription, she established and financed the Nightingale training school at St. Thomas's hospital, London. The first 15 probationers entered the school on July 9, 1860, the date regarded as the birth of modern nursing. The basic principles of what came to be known as the Nightingale system of training, although subsequently often modified, included the following: (1) a trained matron (or superintendent) with undisputed authority over all members of the nursing staff, including those in training; (2) a planned course of theoretical and practical training, the latter to be given in the hospital with which the school was connected; (3) a home attached to the hospital in which carefully selected probationers were placed under a special sister responsible for their moral and spiritual character training.

The financial independence of the Nightingale school gave it the power to arrange for the practical training in the hospital, which should follow the course laid down by the school. The aims of the school were (1) to train the ordinary, or nurse, probationers as nurses for hospitals and for attending the sick poor at home, and (2) to qualify the pupils of superior education, *i.e.*, the lady,

or special, probationers, to become heads of new schools to train others. The Nightingale training was rooted in Christian ideals, based on strict discipline and imbued with a crusading spirit. It opened the door to a new profession for women.

Florence Nightingale's work and writings also emphasized the need for health teaching. In 1859 William Rathbone, in Liverpool, had introduced district nursing by employing a trained nurse to care for the sick poor in their own homes. In 1861 he wrote to Miss Nightingale for advice on how to establish a body of nurses trained for such work. In 1875 the Metropolitan and National Nursing association was established with her support. In 1887, to commemorate Queen Victoria's jubilee, a nationwide organization known later as the Queen's Institute of District Nursing was founded with the aim of preparing and maintaining nurses to care for the sick in their own homes.

By the end of the 19th century the Nightingale principles had been adopted by nurses' training schools connected with both voluntary and tax-supported hospitals in the English-speaking countries and had exerted some influence in continental Europe. The value to hospitals of nursing service by probationers, plus lack of endowments for independent schools, led to a type of apprenticeship training.

Professional Development.—Owing to the increasing demand for trained nurses in hospitals and elsewhere in the community, the need for a professional organization was apparent to some of the leading nurses in England before the end of the 19th century. The first such association was the British (later Royal) Nurses' association, founded in 1887 by Mrs. Bedford Fenwick, who before her marriage was matron of St. Bartholomew's hospital, London. One of the main objectives of the association was to obtain government registration for nurses and statutory control over standards of training. Several efforts were made without success to get a nurses' registration bill through parliament. The profession itself was divided on this issue: Mrs. Fenwick and her supporters believed that such a step was necessary in the interests of patients as well as of nurses; Miss Nightingale, on the other hand, was bitterly opposed to registration. She held that such action was premature and that examinations, which could never test the qualities of a nurse, would merely "standardize mediocrity." From 1887 to the end of World War I, the arguments for and against registration continued. In 1916 the College of Nursing, now the Royal college, was founded; one of its aims was to press for statutory recognition of the trained nurse. Finally, a nurses' bill was sponsored by the minister of health and the first Nurses act received the royal assent in Dec. 1919.

The State and Nursing.—The Nurses act, 1919, established the General Nursing council for England and Wales as the statutory body responsible for forming and maintaining a register of nurses. Similar acts established statutory bodies for Scotland (1919) and Northern Ireland (1922). The councils have the duties of approving hospitals as nurses' training schools, formulating the syllabus to be covered and conducting the examinations for admission to the register. Although the original intention was that this should be a register of general trained nurses, supplementary parts of the register were established, as a result of representation from special fields of nursing, for sick children's, fever (infectious disease) and mental nurses. There was a separate part for male general nurses, but this was later amalgamated with the general part of the register. The male nurse undergoes the same kind of training and largely performs the same duties as the female nurse, except that his study tends to specialize in genitourinary conditions in place of gynecology and midwifery.

The next legislation initiated was the Nurses act, 1943, which empowered the General Nursing council to form and maintain a roll of assistant nurses, to lay down the conditions for their training and to conduct the assessment for admission to the roll. This act also limited the right to use the title "nurse" to registered nurses, enrolled assistant nurses and those in training for admission to the register or the roll.

The National Health Service act, 1946, which was implemented in July 1948, brought all hospitals, with a few exceptions, under state ownership and in addition the community health services, including general medical practice, became part of the national service. The majority of nurses working in the United Kingdom are employed within the national health service, either in hospital, public health or midwifery. Salaries and conditions of service for all these nurses and training allowances for students and pupil nurses are nationally negotiated by the Nurses and Midwives Whitley council, composed jointly of a management and a staff side, this being one of the nine functional councils of the Whitley Councils for the Health Services.

In 1949 a further act enlarged the membership of the General Nursing council and gave it power to approve experimental programs of nurses' training and to allocate funds to hospital authorities for nurses' training. Regional committees were set up under the National Health Service act under the name of Area Nurse-Training committees to advise and assist nurses' training schools in their respective areas. The 1949 act also gave the council power to register nurses who had trained abroad. In 1957 a new act consolidated the previous 1919, 1943 and 1949 Nurses' acts.

The treatment and care of persons suffering from mental disorders was formerly largely limited to custodial care, which had as its main aim preventing the patient from harming himself or other people. The admission of patients and the administration of institutions for the mentally sick or the mentally subnormal were governed by the various acts relating to lunacy and mental treatment passed between 1890 and 1930 and the Mental Deficiency acts of 1913 to 1938. As knowledge of and interest in mental illnesses increased, the old idea of providing primarily custodial care gave way to the conception of the hospital as a therapeutic community. The Mental Health act, 1959, repealed the previous acts and hospitals for the mentally disordered are no longer differentiated by any legal or statutory requirements from hospitals admitting other types of patients. The act also envisaged considerable changes and progress in the treatment of mental illness in the hospital and in the community.

Nursing Education and Training.—The extension and development of the medical and health services, resulting from an increased knowledge and understanding of the causes and processes of disease and from the changed social pattern of modern life, have not only extended the scope of the nurse's work but also have made her responsibilities increasingly more complex and exacting. Furthermore, she is now expected to take part in the regular life of the community; no longer is she set apart by compulsory residence within the nurses' home of the hospital, nor is she isolated by long and inconvenient hours of work and a low level of remuneration, conditions that had made it difficult for her to participate in normal social and cultural pursuits. The basic preparation for nursing underwent many adjustments until it came to be considered a form of adult education as well as training for skilled professional service. Postcertificate education became increasingly necessary in order to prepare the nurse for work in a special field, or for community service, or to qualify her for teaching and administration.

The basic training course for the general part of the register (state-registered nurse, abbreviated S.R.N.) is undertaken in a hospital, or group of hospitals, approved by the General Nursing council for this purpose and, with the exception of certain experimental programs of training, covers a period of three years. Qualified nurse-teachers and medical lecturers are responsible for the theoretical side of the training; practical experience must include general medicine and training in surgical, sick children's and (except for men students) gynecological nursing. A variety of experience is gained under general medicine and surgical nursing in most training schools, such as ear, nose and throat, eye and orthopedic conditions. Many training schools include in addition one or more periods of specialized experience within the three-year training, for example, geriatric or psychiatric nursing, and obstetrical nursing for women students.

A few training schools have included some practical experience in home nursing and health teaching outside the hospital in their basic training, and some interesting experimental projects aim at preparing the nurse both for general nursing and for work in the

public health field and home nursing in a combined course of approximately four years' duration.

Training in psychiatric nursing for the qualification of registered mental nurse (R.M.N.) or registered nurse for the mentally subnormal (R.N.M.S.) also takes three years, but a nurse who is already admitted to one part of the register can qualify for admission to a second part in a shorter period. This is normally two years, but a number of training schools have been allowed, under the provision for experimental programs of training, to give an 18-month postregistration training to general trained nurses. Similarly the qualifying course for registration on the part of the register for sick children's nurses (R.S.C.N.) is of three years' duration. A number of training schools combine this course with preparation in general nursing; the dual qualification (*i.e.*, as S.R.N. and R.S.C.N.) can be obtained in four years' training. The training for admission to the part of the register for fever nurses (R.F.N.) is of two years' duration and again the training can be combined with general training to give the dual qualification. However, the diminution of the incidence of infectious diseases has reduced the number of hospitals required for this purpose, although there is a continuing need for isolation units.

The majority of training schools for the register set their own standards for admission in terms of general education. In July 1962 it became compulsory in England and Wales for all candidates who did not hold a recognized educational certificate to pass the General Nursing council's entrance test. The minimum age of entry to training under the council's rules is 18.

Training for the roll (see *The State and Nursing* above) is of two years' duration. In 1960 the term "assistant" was withdrawn from the title "state enrolled assistant nurse," and the qualification "state enrolled nurse" was authorized in parliament. The assessment (the type of examination used in this training) may be taken at the end of one year, although many training schools prefer to enter their pupils at the end of 18 months' preparation. This type of training is mainly practical, but a certain amount of relevant theoretical work is necessary and each approved training school must appoint a nurse to give this teaching. Any type of hospital that can meet the General Nursing council's requirements may be approved for this training, but the pupil nurse is required to have experience in the nursing of men, women and children (except in the case of male pupils) and to work in both long-stay wards and wards for acutely ill patients.

The many and varied courses available to nurses after registration are for the most part not the responsibility of the General Nursing council, with the exception of the training of nurses as teachers. The General Nursing council (for England and Wales) and the councils for Scotland and Northern Ireland have the duty however, of registering qualified teachers for schools of nursing. The regulations for such registrations are laid down in consultation with the university under whose aegis the course is conducted: in the case of the General Nursing council for England and Wales this is the University of London; in Scotland the course for nurse-teachers is conducted by the nursing studies unit in the University of Edinburgh. Courses are offered by professional nursing groups and other bodies and some courses, in addition to the teachers' course mentioned above, are associated with a university.

Apart from the combined experimental programs of training, additional qualification is required for public health nurses after they qualify for registration. District nurses' training under the Queen's Institute of District Nursing, Ranyard nurses or a local health authority is a four or six months' course, followed by examination for the national certificate of the ministry of health. Local health authorities have a statutory duty (under the National Health Service act, 1946) "to make provision for the visiting of persons in their homes by visitors to be called "health visitors" for the purpose of giving advice as to the care of young children, persons suffering from illness and expectant or nursing mothers, and as to the measures necessary to prevent the spread of infection."

The present function of the health visitor is primarily health education and the care of mothers and their young children. She also has responsibility for the prevention of illness both mental and physical, the care of the mentally subnormal, also the physically handicapped, the aged and infirm. She may be employed on general duties, or as a school nurse or in special projects or conditions such as tuberculosis. The examining body for the health visitor's certificate was the Royal Society for the Promotion of Health until the Council for the Training of Health Visitors was appointed in 1962 by the government. The course lasts one academic year, following registration as a general or sick children's nurse and successful completion of the first part of the midwifery course (six months).

Although the majority of midwives in England are also trained nurses, the training and control of midwives is conducted by a separate authority, the Central Midwives board. Statutory control of the practice of midwifery antedated similar control of nursing by 17 years, the Midwives act having been passed in 1902. For registered nurses midwifery training is a one-year course that may be taken in two parts. Part I is required for many nursing positions, part II for those intending to practise as midwives. The training is for two years for those without registration as a nurse, and the minimum age of entry is 20. (*See* also MIDWIFERY.)

Nursing Service.—The qualified nurse has a great range of opportunities from which to select the type of work best suited to her. As a staff nurse or ward sister in a hospital she may care for patients of any age from premature babies to the aged sick; she may work in medical or surgical units or in research wards where radioactive substances are used in diagnosis or treatment; in operating theatres she will be one of the surgical team carrying out operations of all kinds; she will assist in the treatment and investigation of all the varied conditions seen in the casualty (emergency) and outpatient departments. If specially suited to teaching or administration she may qualify as a tutor or matron after adequate nursing experience.

All local authority health services employ midwives, district nurses, school nurses and health visitors; many appoint specially prepared nurses with experience as supervisors and public health nurse tutors. Outside the health service nurses specially concerned with welfare and the prevention of illnesses or injury are employed in major industrial and commercial concerns as occupational health nurses. Private nurses, maternity nurses and private visiting nurses work independently or through a co-operation (*e.g.*, an employment register conducted by a nurses' association) or a private employment agency.

Hospitals in prisons are staffed by nurses appointed to the nursing service of the government prisons; these nurses also provide the maternal and infant welfare services required and nursing care in preventive detention institutes.

State-registered nurses serve as officers with the armed forces in Queen Alexandra's royal naval nursing service, Queen Alexandra's royal army nursing corps and Princess Mary's royal air force nursing service, each of which has a matron in chief. Nurse training is also offered in all three services to noncommissioned ranks, who thus qualify for registration by the General Nursing council.

Nursing appointments abroad are available, through Queen Elizabeth's overseas nursing service, in colonial and former colonial countries where rapid development increased the number of nursing schools with curricula and standards comparable with those in Britain. As the numbers qualifying from these schools increased, the new nurses were expected to staff the hospital and health services of the country, but there continued to be a great need for nursing administrators and teachers to help develop these services.

In the local, regional and national administration of the hospital and health services of the United Kingdom, nurses were being appointed in the 1960s as nursing officers or as members of advisory councils or boards of management. They also were appointed as members of special teams, research groups and planning commissions. Nurses are elected to the council responsible for nurses' training and registration; nurses appointed as chief nursing officers in government departments (*e.g.*, the ministry of

health) take part in the planning and administration of nursing and allied services at the national level.

The number of nurses practising in Britain cannot be stated with complete accuracy because of fluctuating conditions and the varied bases for making personnel returns. In the British national health services in Sept. 1962 there were the following: in hospitals, 54,902 full-time nurses and 18,470 part-time nurses (not including midwives); in local health services, 10,588 domiciliary nurses (including 352 male nurses), 7,884 midwives, 4,657 general health visitors, 367 health visitors who specialized in tuberculosis and 544 clinic nurses. Health visitors are also employed as school nurses (under the ministry of education) and occupational health nurses may be health visitors but neither they nor private nurses come under the health service, so that figures for them were not available.

OTHER COUNTRIES

In Canada, Australia, New Zealand and South Africa, the early development of the nursing service and of nurses' training followed, as might be expected, the British pattern as established by Florence Nightingale. Geographical and other factors influenced their later developments, as, for example, in Canada, where the close relationship between that country and the United States considerably influenced nurses' training and led to the increasing adoption of graduate courses leading to a degree in nursing. Also in Canada, especially in the French-speaking regions, there existed hospitals and nurses' training schools that had been under the direction of French religious orders from early days. In Australia and New Zealand nursing continued to develop along lines very similar to those in the United Kingdom.

In several European countries, notably in those of Scandinavia and of Finland and the Netherlands, professional nursing had achieved a high standard by the end of the 19th century. The schools were frequently attached to hospitals, following the English custom, but many were modeled on the motherhouse pattern, whether run by deaconesses or by the Red Cross. Other schools were organized by Roman Catholic orders, which in many countries (*e.g.*, France, Italy, Belgium and Germany) are actively concerned with hospital and public health nursing.

In the modern age of quick and easy transport, and with the increasing desire of professional people everywhere to have worldwide contacts with their colleagues, nurses from the United Kingdom, Canada, Australia, New Zealand and South Africa are finding many opportunities of visiting and working in each other's countries. Registered nurses from one country may be accepted as fully qualified professional nurses in other countries, although registration is not automatic.

Possibly nowhere has the development of the profession made more rapid strides than in such present or former British Commonwealth countries as those of east and west Africa, the Caribbean territories, the far east, India, Burma and Malaya. The government medical and nursing services formerly depended on the United Kingdom for their senior medical and nursing staff and the only nurses' training given locally was at first often necessarily of a simple type, partly on account of language difficulties, partly because of the lack of opportunities for general education. In a number of countries tradition or religious customs did not favour women's taking part in any kind of public activities and they particularly were against any form of nursing that required women to work in male wards. When such countries became independent, nurses and midwives boards or councils were established and were made responsible for registration and for the standards of training. Also established were schools of nursing that met or would soon meet the requirements for full professional training. Nursing progress in these countries was also greatly helped by the hospitals and schools established by religious bodies of many denominations and from many countries. It may be truly said that the missionary societies were, in many cases, the first authorities to provide education, and through their schools they materially aided the advances in both medical and nursing training, since progress in establishing such training depended on the attainment of a satisfactory level of general education. Full university education became available to an increasing number of persons in many of these countries, and where a faculty of medicine is included in the university program an undergraduate medical teaching hospital provides the spearhead for progress in both medicine and nursing.

An increasing number of nurses who receive their basic training in their own country in Asia, Africa and the Caribbean now travel abroad to Europe and elsewhere to take advanced nursing courses that prepare them for posts of the highest level in their own nursing service. At the same time, some of these countries need help from outside and a number of posts are open to nurses from the countries with established nursing services.

In many countries, including most European countries, the nursing service and the training of nurses is undertaken both by religious bodies and by the state or the national Red Cross society. In general, the duration and scope of the training is broadly comparable to the training of the registered nurses in the United Kingdom, although in some countries, such as Finland and France, considerably more emphasis is placed on the dual aim of the basic training of the student, *i.e.*, preparing her for work in the public health field and in the hospital. However, the need for closer contact between community and hospital nursing services is everywhere now recognized. Again, apart from language difficulties, very few barriers prevent nurses from profiting by contact with their colleagues in any part of the world. In some instances, regulation regarding work permits will not allow the paid employment of foreigners, but the exchange of nurses, particularly for study and visits of observation, is in most cases arranged without difficulty by the national nurses' associations through the exchange program of the International Council of Nurses.

INTERNATIONAL NURSING

As countries develop their health and hospital services the need for more and better qualified nurses becomes apparent. The World Health organization, after the First World Health council in 1948, adopted three gradually defined objectives concerning nursing in each country: enough nurses to assure the nursing service required for preventive and curative work; nurses capable of leadership in teaching and administration; and nurses able to participate in the planning of health services. The first teams sent to countries to tackle such problems as malaria, tuberculosis and venereal diseases, or to develop maternal and child health services, included a nurse member. Later, international teams included a senior nurse educator, a midwifery tutor and a public health nurse, all three of whom worked with the national staff in selected schools in order to form the qualified staff the country would continue to need for providing the necessary services.

Differences in nurse training in the rapidly developing countries include: combining the preventive with the curative aspects throughout training; including maternity nursing in the basic program; and introducing some preparation in teaching and administration.

The International Council of Nurses (I.C.N.), a federation of independent self-governing nurses' associations, was founded by Mrs. Bedford Fenwick of England in 1899. The first three member groups were the associations of the United Kingdom the United States and Germany. By 1961 national nurses' associations in 59 countries had joined the council and a nurse representative had been appointed in 12 other countries. The first international congress was held in Buffalo, N.Y., in 1901. The I.C.N. maintains contact with the World Health organization and other UN agencies such as the Economic and Social council, the International Labour organization and the United Nations Children's fund; in addition it belongs to the International Hospital federation and the World Federation for Mental Health. The objectives of the I.C.N. are the promotion of self-governing national nurses' associations in order to provide and maintain the highest standards of nursing service and nursing education, to promote the economic and social welfare of nurses and to encourage the interchange of knowledge and ideas on all matters relating to nursing as a professional service. *See* also HOSPITAL; RED CROSS.

UNITED STATES

History.—The beginning of professional nursing in the United States dates from the early 1870s, when the first schools of nursing were established. Prior to that time the sick in hospitals were cared for by members of religious orders, both Roman Catholic and Protestant, or by untrained employees.

The first secular hospital was established on Manhattan Island by the Dutch West India company in 1658 as a pesthouse for soldiers and sailors. It later became a combination of city poorhouse, house of correction and penitentiary, orphan asylum and hospital for the pauper sick and insane. Much later, it became Bellevue hospital. Old Blockley, founded in 1713 in Philadelphia, had a similar history and characteristics—squalor, filth, high death rate, indifferent medical staff and ignorant, rough attendants. It was to become the Philadelphia General hospital many years later.

The Pennsylvania hospital, founded in Philadelphia in 1751, was the first secular hospital without workhouse qualities. The New York hospital was founded in 1771. Each of these employed a staff of nurses who were paid though they were still classed as domestics and had no training. Valentine Seaman, a physician at the New York hospital, developed in 1798 a course of 24 lectures for nurses, the first organized training for nurses in the U.S.

Nursing services for mothers and infants at home were first provided by the Ladies' Benevolent society of Charleston, S.C., in 1813 and by the Philadelphia Laying-in charity in 1828. Later, the "nurses" in these services were given small amounts of instruction.

When the American Civil War began, no trained nurses were available. Volunteer women in New York city organized the Women's Central Association of Relief, which later became the U.S. Sanitary commission. The commission organized volunteer groups, initiated intensive short training programs and disseminated literature on care of the sick and injured to government and other agencies and to some groups in the south. Its work could be considered similar to that of the modern American Red Cross. About 2,000 women volunteered in the south and the north. Most of the Civil War nursing for both armies was done by untrained volunteers and by orderlies drawn from enlisted men.

Dorothea Dix, who had organized the Western Sanitary commission, was designated by the U.S. government in June 1861 as superintendent of nurses. Clara Barton (*q.v.*), who in 1881 was to persuade the government to ratify the Geneva treaty of the Red Cross, served as a nursing volunteer during the Civil War.

After the war the reform movement in all health fields, including nursing, moved ahead rapidly. Louisa Lee Schuyler, who had served on the U.S. Sanitary commission and later in the State Charities Aid association (New York), organized hospital visits to study conditions in that state. At Bellevue the reformers found that patients were neglected and that nurses were vagrants or workhouse prisoners who terrorized the sick, accepted fees and could not be trusted with medicines or food. Action was taken at once to establish a school of nursing based on the Nightingale pattern. The school at Bellevue was established in 1873 along with two others in New Haven, Conn., and Boston. Opponents of this plan, among them physicians who did not approve of the school's independence and its direction by a nurse, were soon won over by the excellent nursing care given by the students and young graduates of the school.

The number of schools of nursing increased rapidly in the next 50 years, reaching more than 2,500 by 1925. The independence of schools from hospitals weakened markedly as the years passed, as did the idea that students were to receive selected educational experiences rather than to staff the hospital. Graduates found employment primarily with private patients at home, or sometimes in hospitals; only after 1930 did hospitals begin to employ graduate nurses to care for their patients and at the same time they began to decrease their dependence on student nurses to provide the major portion of their nursing services.

The first state law setting forth requirements for state examination and registration of nurses was passed in 1903 by North Carolina. All states had such laws within 20 years.

In 1886 visiting nurse societies began to expand. A new approach, a nurses' settlement on Henry street in New York city, was established by Lillian Wald in 1893. She coined the phrase "public health nurse." Miss Wald played a leading role in starting school nursing (in New York, 1902), helped establish home visiting by nurses to industrial holders of life insurance policies (1909), participated in the institution of a rural public health nursing service by the American Red Cross in 1912 and promoted the establishment of the Children's bureau in 1912.

Visiting nurse societies were established in large cities, often with financial support from community chests and philanthropic agencies. Many public health nursing methods received their initial trial in these societies, spreading later to official public health nursing agencies.

When tuberculosis was found to be a preventable disease, city health departments began about 1900 to employ nurses to visit patients in their homes, often at the insistence of and with help from tuberculosis associations. As public health movements expanded and government health agencies in states, cities and counties increased in number and scope, nurses were employed in greater numbers and for a wider variety of activities, first for special programs, later as generalists.

An unusual agency in a rural area was the Frontier nursing service, organized in 1925 by Mrs. Mary Breckinridge to carry out a nursing program among mountain families in southeastern Kentucky. The service began in a county without roads passable to motor traffic, and the nurses rode horseback. By the mid-1960s the service had been extended over a four-county area with a population of more than 9,000 and its facilities had been expanded to include a hospital directed by a physician, outpost clinics staffed by nurse-midwives and a school of midwifery.

The first national organization in nursing was founded after a conference on hospitals, dispensaries and nursing at the Chicago World's fair of 1893. At first it was called the American Society of Superintendents of Training Schools for Nurses, and in 1912 it became the National League of Nursing Education. Improvement of nursing education throughout the United States was its aim.

A second organization, called the Nurses Associated Alumnae of the United States and Canada, was founded in 1896. All nurses were eligible for membership. The organization, which became the American Nurses' association in 1911, focused its attention on problems of practice and legislation and the legal status of nurses. State and district associations were established throughout the nation.

In 1912 the National Organization for Public Health Nurses (later Nursing) was founded for the purpose of improving services in both government agencies and the growing number of voluntary visiting nurse services. It also carried on a program of improvement and standardization in the education of public health nurses.

The National Association of Colored Graduate Nurses was formed in 1908. It worked for higher standards of education and development of leaders among the group and against discrimination. While none of the other national organizations in nursing had excluded members on the basis of race, some state branches did so. The aggressive and successful efforts of the National Association of Colored Graduate Nurses, with support of the other organizations, culminated in the dissolution of this association in 1951 and the merging of memberships.

Just as the Civil War called national attention to the importance of nursing to the nation, so did subsequent wars. The Associated alumnae had pressed for use of qualified nurses in the Spanish-American War and the organization of a nurse corps in the military establishment. The army nurse corps was authorized in 1901 and the navy nurse corps in 1908. In 1909 the Associated alumnae volunteered to organize a Red Cross nursing reserve to act as a group of trained nurses to serve in disasters as well as in war. Jane Delano of the Red Cross led the combined planning so that by World War I this plan was in operation. After the war it provided both military and civilian nurses for work in former Spanish colonies and initiated the interests of American nursing in international health. During World War II, recruit-

ment to the military nurse corps became direct, with strong support of the Red Cross.

The first five nursing education programs in colleges or universities combining general and professional education and leading to the bachelor's degree were founded in 1916. The first university course for graduate nurses was given in 1899 and this expanded into programs at Teachers college, New York, in which nurses could qualify for the bachelor's degree and later for the master's and doctoral degrees. Other universities also developed both basic and advanced programs.

From the end of World War I through 1950, nursing experienced many studies and self-analyses. Among these was the Goldmark report in 1923, financed by the Rockefeller foundation, which revealed needs for an improved educational system. The Grading Committee study (1927–34) resulted in information needed for improvement and in many recommendations for improvement. The national organizations, with support from many sources, implemented many of these recommendations.

World War II greatly increased the demands for both civilian and military nurses. Congress authorized the Cadet Nurse corps program, in which nearly 170,000 students were recruited for schools of nursing. Nurses volunteered in large numbers for military service and at the peak period in 1945 there were more than 70,000 nurses in the U.S. armed forces. Nursing and related organizations and government nursing services worked together through the National Nursing Council for War Service.

Following the war, the national nursing associations were reorganized. Five associations—the American Nurses' association, the National Organization for Public Health Nursing, the National League of Nursing Education, the Association of Collegiate Schools of Nursing (founded 1933) and the National Association of Colored Graduate Nurses—became two groups in 1952, namely, the reconstituted American Nurses' association and the National League for Nursing. The former is composed solely of nurse practitioners and the latter is composed of nurses, practical nurses and aides, physicians, general educators, hospital and public health administrators and private citizens, as well as of institutional members—*e.g.*, schools of nursing and public health nursing agencies.

Current Situation.—More than 500,000 professional nurses were at work in the U.S. in the mid-1960s. They provided nursing services in more than 7,000 hospitals, 3,500 public health agencies, and in health programs in 4,000 public school systems. Some served in physicians' offices, nursing homes and in industrial plants. Nurses provided direct services in all these situations and also supervised and administered nursing services. They taught in schools of nursing and served as directors and deans of these schools. Some served as consultants with government and voluntary agencies. Some assisted in the conduct of research or carried on their own researches. Some wrote the literature of nursing. More than 60% of the 500,000 nurses worked in hospitals. About 1% of the nurses were men.

Another nearly 500,000 professional nurses in the U.S. are inactive in nursing. Most are married and in younger age groups. Beginning in 1950 an increasing number of these nurses returned to active status, many on a part-time basis. Nurses can usually resume active practice without additional training other than a refresher course, which usually is provided by the employing institution.

About 250,000 practical nurses work in hospitals, physicians' offices and nursing homes. In hospitals approximately 400,000 nursing aides, trained only on the job, assist nurses in caring for patients. The high ratio of untrained workers in hospitals underscores the shortage of professional and practical nurses.

The number of professional nurses was increasing more rapidly in the 1960s than the population of the United States. But the demand for services was increasing more rapidly than the supply of nurses. Factors creating the demand for nurses were: rapid scientific advance in medicine; expansion of hospitals and other health facilities and agencies; and an increase both in the population and in the proportion of it that seeks health care. Each medical discovery adds new ways in which nurses can serve; and more people were demanding the new benefits. Insurance plans for prepayment of hospital and medical expenses and widespread information about health and sickness bring more people to health facilities. New plans for care of the chronically ill and aged in their own homes require more nurses. Development of better community and institutional services for the mentally ill and mentally retarded was expected to increase the demands for nursing services still more.

The demands for nursing services increase qualitatively as well as quantitatively and bring changes in education for nursing. Deeper background in biological and physical sciences is required to understand and use the new diagnostic and therapeutic measures; greater knowledge of behavioural and social sciences is required to understand community relationships and health-related services as well as to gain insight into patients' feelings about illness and motives for recovery. For these reasons, collegiate education for nurses came to be emphasized.

The educational system for nursing is comprised of three major types of programs: (1) the collegiate program, four years in length, combining professional and general education and leading to the bachelor's degree; (2) the hospital school program, three years in length, leading to a diploma; and (3) the junior college program, two years in length, leading to an associate degree. Graduates of all these programs are eligible to take the state examination; after passing it, they are authorized to use the title registered nurse (R.N.).

There were approximately 175 collegiate programs, 850 hospital schools and 100 junior college programs in the U.S. in the mid-1960s, graduating about 32,000 nurses each year.

For advanced and special education, nurses undertake graduate study in universities. Thirty-four universities offered a variety of graduate programs in the mid-1960s. More than 1,000 nurses receive master's degrees annually and a small but growing number receive doctoral degrees. These nurses are qualified for administrative, teaching, supervisory, research, clinical specialist or consultative positions.

Practical nurses are prepared in one-year educational programs, some of which are operated by hospitals although most are conducted by vocational schools. The rapid expansion in practical nurses' schools after World War II was in large part attributable to federal financial aid under a vocational education program. There were more than 700 schools of practical nursing in the United States in the mid-1960s. After completing a state-approved program, graduates are eligible to take the state examination and, after passing it, to use the title licensed practical nurse (L.P.N.) or, in a few states, licensed vocational nurse (L.V.N.). A considerable number of practical nurses who achieved their skills through experience, not training, are licensed under a waiver of regulations. This number decreases each year.

The definitions of the practice of professional nursing and of practical nursing, and the legal control of practice, are established by the nurse practice acts of each state. The American Nurses' association has formulated items that it recommends for inclusion in such legislation; it seeks revisions of state laws so that standards of education and practice attain a uniformly high level.

The American Nurses' association formulates and promotes a code of ethics for members of the nursing profession, as does the National Federation of Licensed Practical Nurses for practical nurses. The American Nurses' association operates a program aimed at economic security for nurses. It also works to increase the clinical competence of its members. Through the association nurses of the United States are members of the International Council of Nurses.

The National League for Nursing operates a voluntary accreditation program for schools of nursing. About 60% of the U.S. nursing schools are so accredited. The league provides information for recruiting students to the schools and also maintains a program of school improvement; similarly, it works to improve public health nursing services through its member agencies.

The official organ of the American Nurses' association is the *American Journal of Nursing* (founded in 1900); *Nursing Outlook* is the official publication of the National League for Nursing.

A quarterly journal, *Nursing Research*, is sponsored by both.

The nursing councils of two regional organizations—the Southern Regional Education board and the Western Interstate Council on Higher Education—carry on programs aimed at improving nursing education in their regions.

Government Role in Nursing.—Several departments of the federal government carry on activities in nursing. The department of labour compiles and distributes manpower and salary data on nursing. The department of defense maintains three corps of nurses—army, navy and air force—totaling about 8,500 nurses who staff military hospitals and plan the nursing role in national defense. The Veterans administration is the largest single employer of nurses in the United States; about 15,000 nurses work in its hospitals.

The children's bureau of the department of health, education and welfare provides leadership to nursing in the care of mothers and babies; the office of vocational rehabilitation plays a similar role in restorative nursing. The office of education administers the program of federal aid for practical nurse education.

The public health service of the department of health, education and welfare employs 2,500 nurses. In addition to operating its hospitals, which include those for American Indians, this service conducts research in nursing and administers a research grant program. It also administers scholarship programs under which, by the mid-1960s, 11,000 nurses had completed graduate preparation for teaching and administration and 2,500 nurses had completed graduate study in mental health nursing. It also provides nursing consultation service to voluntary and official health agencies and institutions in a wide variety of public health fields.

Most states employ nurses in state hospitals, the state health department and other governmental agencies. County and local governments employ nurses in similar capacities. (L. P. LE.)

NUSAYBIN (NISIBIN; ancient NISIBIS), a small frontier trading town of Mardin *il* (province), Turk., situated near the Syrian border about 130 mi. N.W. of Mosul, Iraq. Administratively, it is the centre of a *kaza* (district) of the same name. Pop. (1965) town 7,241, district (1960) 29,685. It lies at the point where the Gorgarbonizra river (Cagcaga, Jaghjagha; ancient Mygdonius) passes through a narrow canyon and enters the plain, and strategically, like Edessa, it commanded the entrance of the valley country from the mountains. During the Assyrian empire it formed a frontier fort against aggressions from the north and occupied a similar position in Seleucid times. From the middle of the 2nd century B.C. until the early years of the Christian era, it was the residence of the kings of Armenia. The fortress was important during the struggle between Rome and Parthia, and it became a Christian centre with a Nestorian (*see* NESTORIANS) and a Jacobite bishop. Under the caliphs it was a frontier stronghold and the scene of continuous fighting. It finally declined because of internal troubles and, according to the Arab chroniclers, the compulsory substitution of wheat for fruit crops. Nusaybin remains of some significance, however, because of its position on the upper trade route from Mosul to the west and its location on the Aleppo-Baghdad railway.

(N. TU.; S. ER.; E. TU.)

NUSKU, a light and fire god in the Sumero-Akkadian pantheon. Shulgi, second king of the 3rd dynasty of Ur, *c.* 1900 B.C., gives the god the title "exalted vizier of Enlil"—*i.e.*, of the second member of the cosmic triad of deities. On tablets of the same period from Drehem, near Nippur, Nusku is named together with Nergal, the god of the underworld, in lists of offerings. His father was Sin, the moon-god, whose cult centre was at Ur in Sumerian times and at Harran in Neo-Babylonian times. But while Sumerian tablets from Ur do not mention Nusku, a historical text relates how Nabonidus, the last Babylonian king, brought him from Babylon to Sin's temple at Harran (6th century B.C.).

Semitic texts describe Nusku as the king of the night, who illumines the darkness and repels the demons of the dark. On Babylonian boundary stones he is identified by a lamp. He is visible at the new moon, hence is called its son. The last day of the month is sacred to him, so that he is a lunar deity. He figures much in incantations and rituals as the fire. Without his firelight there would be no banquets for the gods, no sweet smell of incense, nor could Shamash, the sun-god, exercise judgment. In an Assyrian prayer Nusku is described as "counselor of the heart of the god Marduk."

A temple rubric of Seleucid date from Uruk (biblical Erech) in southern Babylonia directs that Nusku, "with the torch," shall proceed with other deities to the sanctuary of the goddess Antu, wife of Anu, god of heaven.

On stele of the 7th century B.C. from Nerab near Aleppo, Nusku, written Nushku, is named alongside the Aramaean moon-god Shahar.

For bibliography, *see* ADAD. (T. FH.)

NUT, generally any seed or fruit consisting of a kernel, usually oily, surrounded by a hard or brittle shell. Most edible nuts, *e.g.*, almond, walnut, Brazil nut, peanut, etc., are well known as dessert nuts. Not all nuts, however, are edible; some are used as sources of oil or fat and may be regarded as oil seeds (*see* OIL PLANTS); others are used for ornament. The botanical definition of a nut, based on morphological features, is more restrictive: a hard, dry, one-celled, one-seeded fruit that does not split open at maturity. Among the nuts that fit both the botanical and popular conception are the acorn, chestnut and filbert; other so-called nuts may be botanically seeds (Brazil nuts), legumes (peanuts) or drupes (almond, coconut, pecan and walnut). In this article the term nut will be used in its broadest sense unless otherwise indicated.

IMPORTANCE AND USES

Dietetic Value and Use as Food.—From the earliest times nuts have been food for man and are still of great importance in many parts of the world; *e.g.*, the coconut in the eastern tropics and the groundnut in China, India and Africa. In most western countries nuts do not constitute part of the staple diet, except perhaps of vegetarians, but they are popular for between-meal snacks and as dessert. Large quantities of nut kernels are also used in candies and in processed foods of various kinds.

The dietetic or food value of nuts is high; most dessert nuts are rich in protein and oil or fat, and also in mineral matter. Many nut kernels consist of more than 50% fat and average in excess of 20% protein, while vitamins may be present in appreciable quantities. Nuts are therefore a concentrated food.

Most nuts are eaten raw, though some nuts, such as the almond and the macadamia, are equally palatable raw or cooked and others, such as the peanut and chestnut, have a better flavour when cooked and salted. The flavour of nuts is largely dependent on the oils they contain and these may be modified in cooking.

Modern methods of processing, packing and storing nut kernels,

Common names	Scientific name	Original source	Principal use of nut
Almond (sweet)	*Prunus amygdalus*	Mediterranean basin	Food
Almond (bitter)	*P. amygdalus*, var. *amara*	Mediterranean basin	Flavouring extract; oil
Almond, Indian	*Terminalia catappa*	East Indies	Food
Almondette	*Buchanania lanzan*	India, Burma	Food
Araucarian pine nut (piñon, pinyonie)	*Araucaria araucana*	Chile	Food
Arnut (yer-nut, earth chestnut, hawk nut, lousy-nut)	*Bunium* species	W. Europe to Caucasus	Food
Australian nut, *see* Macadamia			
Babassu nut	*Orbignya oleifera*	Brazil	Food; fuel oil
Bambarra groundnut	*Voandzeia subterranea*	Tropical Africa	Food
Barbados nut (physic nut)	*Jatropha curcas*	Tropical America	Medicine
Baroba	*Dispoldiscus paniculatus*	Philippines	Starchy seeds boiled and eaten
Beech nut, American	*Fagus grandifolia*	E. United States	
Beech nut, European	*Fagus sylvatica*	Cent. Europe, S.W. Asia	Salad oil
Ben nut	*Moringa oleifera*	India, West Indies	Artists' oil; lubricant
Betel nut (areca nut, pinang)	*Areca catechu*	E. tropics	Masticatory
Bladder nut	*Staphylea* species	Temperate North America, S. Europe, S. Asia	Necklaces
Bomah nut	*Pycnocoma macrophylla*	Africa	Tanning; poison
Bonduc nut	*Caesalpinia bonduc*	Tropics	Medicine; beads
Brazil nut (castanea, creamnut, para nut)	*Bertholletia excelsa*	N. South America	Food (*see* BRAZIL NUT)
Breadfruit, African	*Treculia africana*	Tropical Africa	Seeds ground for meal
Bread nut	*Brosimum alicastrum*	Tropical America	Food
Butternut (long or white walnut)	*Juglans cinerea*	E. United States, S.E. Canada	Food (*see* BUTTERNUT)
Butter pit, *see* Naras nut			
Candle nut	*Aleurites moluccana*	Malaysia	Drying (*see* ALEURITES)
Cashew (acajou, caja, cajou)	*Anacardium occidentale*	West Indies, tropical America	Food (*see* CASHEW)
Castanopsis nut (golden chinquapin, wild chestnut)	*Castanopsis* species	S.E. Asia, California	Food
Chestnut	*Castanea* species	E. United States, S. Europe, N. Africa, Asia	Food (*see* CHESTNUT)
Chile hazel	*Gevuina avellana*	Chile	Food
Chile pine nut, *see* Araucarian pine nut			
Chinquapin	*Castanea* species	S.E. United States, China	Food (*see* CHESTNUT)
Chufa (rush nut, earthnut, ground almond)	*Cyperus esculentus*	S. Europe	Food
Cobnut, *see* Filbert			
Cobnut, Jamaican	*Omphalea diandra*	West Indies, tropical America	Food; oil
Coconut	*Cocos nucifera*	Tropics	Food; oil (*see* COCONUT PALM)
Cohune nut (cahoun nut)	*Attalea cohune*	Honduras	Oil
Cola nut, *see* Kola nut			
Coquilla nut	*Attalea funifera*	Brazil	Turnery
Coquita nut (coker nut)	*Jubaea spectabilis*	Chile	Oil; food
Coumara nut, *see* Tonka bean			
Dika nut	*Irvingia gabonensis*	W. Africa	Food; oil
Doum nut (dom nut)	*Hyphaene thebaica*	N. and central Africa	Turnery; vegetable ivory
Filbert (hazelnut)	*Corylus* species	E. North America	Food (*see* FILBERT)
Galo nut	*Anacolosa luzoniensis*	Philippines	Food
Gasso nut	*Manniophyton africanum*	W. Africa, Congo	Food
Gevuina nut, *see* Chile hazel			
Ginkgo nut	*Gingko biloba*	China, Japan	Food
Gnetum seed	*Gnetum gnemon*	Tropical Asia	Food
Goat nut, *see* Jojoba nut			
Groundnut (wild bean)	*Apios tuberosa*	North America	Tubers eaten
Grugru nut (corozo nut)	*Acrocomia aculeata*	Tropical South America	Beads; oil
Hazelnut, *see* Filbert			
Heartnut, *see* Japanese walnut			
Helicia nut	*Helicia diversifolia*	Queensland, Austr.	Food
Hickory nut	*Carya* species	North America, China	Food
Hodgsonia seed	*Hodgsonia macrocarpa*	Tropical Asia	Food
Hyphaene nut, *see* Doum nut			
Indian nut, *see* Pine nut			
Inoi nut	*Poga oleosa*	W. Africa	Food
Ivory nut, *see* Tagua nut			
Jack nut	*Artocarpus heterophyllus*	India	Food
Japanese walnut (heartnut, cordate walnut)	*Juglans cordiformis ailanthifolia*	Japan	Food (*see* WALNUT)
Java almond (Luzon or Philippine nut)	*Canarium commune*	Pacific tropics	Food
Jojoba nut (goat nut, sheep nut)	*Simmondsia californica*	California, Mexico	Food; hair oil
Karaka nut	*Corynocarpus laevigatus*	New Zealand	Food
Kola nut	*Cola acuminata*, *C. nitida*	W. tropical Africa	Masticatory; stimulant
Kubili nut	*Cubilia blancoi*	Philippines	Food
Ling (caltrop, lingko)	*Trapa bicornis*	China	Food
Litchi (lychee, Chinese nut)	*Litchi chinensis*	S. China	Food
Lotus seed	*Nelumbium nelumbo*	Asia	Food
Lunan nut	*Olophora fruticosa*	Pacific region	Food
Macadamia (Queensland nut, Australian nut)	*Macadamia* species	Australia, Hawaii	Food (*see* MACADAMIA)
Manketti nut	*Ricinodendron rautanenii*	S. Africa	Food

Common names	Scientific name	Original source	Principal use of nut
Marking nut	*Semecarpus anacardium*	India	Ink; varnish; food
Moreton Bay chestnut (black bean)	*Castanospermum australe*	Australia	Food
Naras nut (butter pit)	*Acanthosicyos horrida*	S.W. Africa	Food; oil
Nicuri Palm nut	*Cocos coronata*	Brazil	Food
Nitta nut (nete)	*Parkia biglobosa*	Tropical Africa	Food
Nutmeg	*Myristica fragrans*	East Indies	Spice
Nut pine, *see* Pine nut			
Olive nut	*Elaeocarpus ganitrus*	India	Beads; ornaments
Owusa nut	*Plukenetia conophora*	W. tropical Africa	Food
Oyster nut	*Telfairia pedata*	E. Africa	Food
Palm chestnut	*Guilielma gasipaes*	Tropical South America	Food
Palm nut	*Elaeis guineensis*	W. Africa	Oil (*see* PALM)
Paradise nut (sapucaia nut)	*Lecythis zabucajo*	Tropical South America	Food
Pascualito nut (pinonchillo)	*Garcia nutans*	Mexico to Venezuela	Quick-drying oil
Peanut (groundnut)	*Arachis hypogaea*	Brazil	Food (*see* PEANUT)
Peanut, hog	*Amphicarpa monoica*	North America	Food
Pecan (Illinois nut)	*Carya illinoensis*	S. United States	Food (*see* HICKORY)
Pekea nut, *see* Swarri nut			
Pili nut	*Canarium ovatum*	Pacific tropics	Food
Pine nut (piñon, pignolia)	*Pinus* species	S.W. United States, Europe, Asia	Food
Pistachio (pistache, green almond)	*Pistacia vera*	Mediterranean basin to S.W. Asia	Food (*see* PISTACHIO)
Poison nut	*Strychnos nuxvomica*	India	Medicine
Quandong nut	*Fusanus acuminatus*	Australia	Food
Queensland nut, *see* Macadamia			
Ravensara nut (clove nutmeg)	*Ravensara aromatica*	Madagascar	Spice
Rose nut (red nut)	*Hicksbeachia pinnatifolia*	Australia	Ornamental; food
Sapucaia nut, *see* Paradise nut			
Sassafras nut	*Ocotea* species	South America	Aromatic
Shea butter nut	*Butyrospermum parkii*	British Africa	Food; soap oil
Singhara nut (water nut)	*Trapa bispinosa*	India, Kashmir	Food
Snake nut	*Ophiocaryon paradoxum*	Guiana	Charm for snakebite
Soap nut	*Sapindus saponaria*	S. Florida to N. South America	Soap substitute
Soap nut, Indian	*Sapindus inocarpus*	India	Soap substitute
Sterculia nut	*Sterculia foetida*	Tropical Africa	Food
Swarri nut (souari nut, sawarri nut, pekea nut, butter nut, piki)	*Caryocar* species	Tropical America	Food
Taccy nut	*Caryodendron orinocense*	Colombia	Food
Tagua nut (ivory nut, vegetable ivory)	*Phytelephas macrocarpa*	Central America	Ornaments; buttons
Tahiti chestnut (South Sea chestnut)	*Inocarpus edulis*	South Seas	Food
Tallow nut (false sandalwood)	*Ximenia americana*	Tropical Africa	Food
Tallow nut, Chinese	*Sapium sebiferum*	China	Wax for soap and candles
Tiger nut, *see* Chufa			
Tonka bean (tonqua or tonquin bean, coumara nut)	*Dipteryx odorata*	Tropical South America	Perfume
Torreya nut (kaya nut)	*Torreya nucifera*	China, Japan	Food; oil
Tropical almond (myrobalan, tavola nut, Demerara almond)	*Terminalia catappa*	S.W. Asia	Food
Tung nut (wood-oil tree)	*Aleurites* species	S. China	Paint; varnish; oil (*see* ALEURITES)
Walnut, African	*Coula edulis*	W. tropical Africa, Congo	Food
Walnut, other	*Juglans* species	W. hemisphere, Iran, China, Korea	Food
Water chestnut (water caltrop)	*Trapa natans*	Europe, Asia	Food
Water chestnut, Chinese (matai)	*Eleocharis tuberosa*	S. China	Food
Yeheb nut	*Cordeauxia edulis*	Somaliland	Food

In particular the use of hermetically sealed vacuum or gas-filled containers, have done much to improve their condition and appearance on reaching the consumer. Nut kernels must be protected against insect (weevil) attack, to which they are very prone, and against rancidity.

Nuts, as human food, are used in a great variety of ways in different parts of the world. They are often ground up or grated in soups and stews (in West Africa groundnut chop, a kind of stew, is a national dish.) They are much favoured in salads and in stuffing for poultry. As ingredients of puddings, cakes and sweetmeats of many forms, nuts are in universal use. Nut butters and pastes of various kinds are popular. Nuts are a common ingredient in ice cream and extensively used, either whole or chopped, for nut chocolate and other sweets and candies; those generally used for these purposes are almonds, pecans, walnuts, Brazil or Barcelona nuts.

Dessert Nuts.—*Almond.*—This is the most universally popular dessert nut. Spain is one of the main producers, supplying the superior Jordan and Valencia varieties. The almond tree grows under a wide range of conditions, but a dry harvesting season is necessary for successful commercial production (*see* ALMOND).

Brazil Nut.—This nut, known also as para nut or creamnut and as *castanha* in Brazil, is one of the best-known and most generally liked of edible or dessert nuts. Like the almond, it is much used in confectionery (*see* BRAZIL NUT).

Cashew.—For dessert purposes the cashew kernel has come to the fore since World War II. Although the tree itself is a native of the Americas, it was carried to other countries by the early Portuguese explorers, and commercial production of the kernels is now centred in India (*see* CASHEW).

Chestnut.—Chestnuts are usually cooked, often roasted, before being eaten. The common European chestnut is often called sweet chestnut or, in Britain, Spanish chestnut. The best, large chestnuts (marron), of rich creamy flavour and definite aroma, are used for *marrons glacés*, the well-known French sweetmeat (*see* CHESTNUT).

Coconut.—The kernel or flesh of the coconut has numerous culinary uses, especially when grated, when it is used in salads, curries, etc. Dried or desiccated coconut, available in several forms and much used in confectionery and home cooking, is pre-

pared from fresh, selected nuts, mainly in Ceylon (*see* Coconut Palm; Copra).

Filbert.—Hazelnuts in the broad, botanical sense include such nuts as filberts, cobnuts, Barcelona and Turkish nuts (these are the small nuts of the nut trade). Their convenient size may account in part for their extensive use in nut foods and nut chocolate (*see* Filbert; Hazel).

Hickory.—There are several kinds of hickory nuts and all are American. Although some are difficult to crack, the better kinds have large plump kernels with a good flavour. These nuts keep well. They formed an important item in the diet of American Indians (*see* Hickory).

Macadamia.—The Macadamia or Queensland nut is native to Australia, as the latter name indicates, but is grown commercially in Hawaii. There are several different recognized varieties. The nuts are spherical in shape, 1½–2 cm. in diameter, with a white, pleasantly crisp kernel with an appetizing, slightly sweet flavour.

Oyster Nut.—It is mainly since World War II that this nut has been marketed as a dessert nut, although it has long been popular in east Africa, where it is indigenous. The nut, the seed of a large gourd, is flat, from 3–5 cm. in diameter, and covered with a fibrous layer that unfortunately prevents the use of mechanical crackers.

Paradise Nut.—This South American nut, also called sapucaia nut, resembles the Brazil nut, to which it is closely allied botanically, although it has a softer shell and softer kernel than the Brazil nut. The nuts are produced in a large woody fruit or "monkey pot."

Peanut.—The peanuts used as dessert nuts are usually specially selected or hand-picked nuts with large pods and large kernels. A light-coloured shell that does not darken unduly on roasting is desirable. These nuts are produced in various countries, notably in the United States, Spain and certain Asian and African countries (*see* Peanut).

Pecan.—This American nut, a member of the hickory family, is widespread in North America in the wild state. The nut somewhat resembles the walnut; there are many varieties.

Pine Nut.—Pine nuts, or pignolias, usually from the European stone pine (*Pinus pinea*), are relished by many people and much used in vegetarian cookery as a substitute for animal fat. As dessert they may be eaten raw, roasted, salted or made into sweetmeats. The kernels of many other pines are also eaten. In North America pine nuts are obtained from the so-called nut pines or piñons.

Pistachio.—This well-known nut, also called pistache, is a native of the Mediterranean region. It differs from all other nuts in the characteristic green colour of the kernel. It is popular, in grated form, for ornamenting dishes. Other features of the nut are its pleasant mild flavour and good keeping qualities (*see* Pistachio).

Swarri.—This little-known South American nut, also called the souari or butternut, from the Guianas, is sometimes imported into Europe and America. It is about four times the size of a Brazil nut with a thick (over 1 cm.) hard shell enclosing a soft white kernel with a good flavour (*see* Butternut).

Walnut.—The common walnut has been used in Europe from very early times as an article of food and in everyday cookery (*see* below). The green or immature nuts are often pickled. There are about half a dozen different species of walnut, the American black walnut and Japanese walnut being among them.

Nuts as Sources of Oil.—Oil for a variety of purposes can be obtained from nuts. At one time walnut oil was a much-used vegetable oil in France, although it is now little used. For centuries walnut oil has also been used for artists' colours, especially for mixing whites and delicate shades. Another nut oil, much used in Europe in the past for edible purposes and also for lamps, is beech nut oil. It is said to be a good frying oil that does not readily go rancid.

The tung nut, from a Chinese tree, yields a nonedible drying oil; it resembles linseed oil and is used for paints and varnishes. In west Africa the shea butter nut yields a fatty oil much used locally and suitable for soap making. The kernel of the babassu nut of Brazil, which grows on a palm, is also a source of oil. The Indian ben nut, the product of a small tree, yields an oil at one time used for lubricating watches. (*See* Oil Plants.)

Nuts as Sources of Starch or Carbohydrate.—A few nuts have kernels of a starchy nature, without the high oil and protein content of most edible nuts. The best-known of these are the chestnuts, notably the common European chestnut. In southern European countries it was an important food for man and his domestic animals for centuries, taking the place of bread or wheat flour in some areas. The closely related North American chestnut has been largely destroyed by disease The Chinese chestnut, now cultivated in other countries, is somewhat similar to the European although the nut is larger.

The so-called water chestnut of the orient and the chufa or tiger nut are not true nuts but the edible tubers of grasslike sedges; they are cultivated as a source of starchy food, especially in China The so-called Bambarra groundnut, a common legume crop in many parts of tropical Africa, may be cooked in various ways.

Nuts as Masticatories.—The betel or areca nut, produced by a palm, is chewed in the eastern tropics by all classes. It imparts a characteristic red colour to the spittle (*see* Betel Nut).

The kola nut is a well-known masticatory with stimulating properties and is widely chewed in west Africa and is also exported.

Other Uses for Nuts.—The finely-ground shells of various nuts may be added as bulk fillers in the manufacture of plastics. Some palms have very hard seeds, nuts or hard kernels that may be used in turnery and for making ornaments. The tagua or vegetable ivory nut, from Central America, which has also been used for making buttons, is the best-known of these. The African doum palm nut is somewhat similar although inferior, as it has a cavity in the centre. The thick, hard shell of the South American coquilla nut was used in the carving and turnery popular in the 19th century.

Marking ink for linen is prepared from the marking nut of India. The clearing nut is another unusual Indian nut. The seeds or nuts are cut open and rubbed round the inside of the rough earthenware vessels used for drinking water: the juice they contain thus impregnates the water and causes impurities to coagulate and sink.

The Chinese litchi nut is really a fruit, not a nut, but has a brittle, though thin, nutlike shell. The bonduc or nicker nut of the tropics is a hard marblelike seed, not edible but sometimes used as beads or as marbles by boys.

PRODUCTION

The world's trade in nuts varies a great deal from year to year as crops are often very dependent upon seasonal climatic conditions. For example, annual exports of the Brazil nut from the Amazon forests during the decade 1950–60 varied from 16,000 tons to 31,000 tons. (There is an increasing tendency to extract and pack the kernels in Brazil to save freight.) The related South American paradise nut is produced only in small quantities exports go mainly to the United States. The cashew is produced to some extent in the American tropics and West Indies but commercial production is mainly in India, annual production there exceeding 60,000 tons in the early 1960s. More than 100,000 tons (in the shell) of East African cashews may eventually go to Indian factories for kernel extraction and processing. The United States consumes more than 70% of India's cashew kernel production. The macadamia nut is produced commercially in Hawaii, where 100–200 tons of kernels annually (early 1960s) are exported in vacuum containers, chiefly to the United States.

Southern European countries, especially Spain and Majorca, are the main producers of almonds, but there is also considerable production in the southwestern United States and to some extent in Australia and South Africa. Walnuts are grown in the same regions as almonds, France being a notable producer. France Spain and Italy are important producers of chestnuts. Among small nuts of the filbert type, Spain is an important producer of Barcelona nuts, and Turkey of Turkish nuts. In Britain the county of Kent is noted for its filberts or cobnuts. Pistachio nuts are produced by various Mediterranean countries and in Asia

VARIOUS KINDS OF COMMERCIAL AND EDIBLE NUTS

1. Pecan (*Carya illinoensis*), variety Schley (Sly)
2. Peanut or groundnut (*Arachis hypogaea*)
3. Cashew (*Anacardium occidentale*)
4. European Filbert (*Corylus avellana*), variety Barcelona
5. European Filbert, variety DuChilly
6. Chinese Chestnut (*Castanea mollissima*): nuts in bur at maturity
7. Chinese Chestnut: top left, kernel with pellicle still attached; right, pellicle removed; below, outer and inner views of end nuts

Minor, and also to a small extent in California. The United States is the main producer of pecans. Italy is the chief commercial source of pine nuts. (F. N. H.)

NUT (Engineering): *see* BOLT.

NUTCRACKER, the name for species of the genus *Nucifraga*, foot-long birds of the crow family (Corvidae). They are found chiefly in evergreen woods of the northern hemisphere, and are known for their habit of storing nuts and other food for the winter. The common European nutcracker (*N. caryocatactes*), of which many races exist, is black-brown, brightly speckled with white, with conspicuous white under tail coverts and white-tipped tail feathers. The beak is blackish, long and thick. The nutcracker feeds mainly on conifer seeds but also takes fruits, insects and young birds. The nest, built about 20 ft. up in a tree, is a large structure of sticks lined with grass. The eggs are pale bluish-green, freckled with pale olive or ash.

Clark's nutcracker (*N. columbiana*), found in America, has a light gray body with white patches on black wings and tail.

NUTHATCH, the name for stubby, little tree-climbing birds, so called from their occasional habit of hacking nuts, which they fix, as though in a vise, in a chink or crevice in the bark of a tree, and then hammer with the bill till the shell is broken. Nuthatches, which constitute the subfamily Sittinae of the family Sittidae, are most numerous in the northern hemisphere; aberrant forms, however, are found in Africa and Australia. Smaller than sparrows, they have long dark bills, short tails, short legs and powerfully taloned feet, features associated with the nuthatches' remarkable adeptness at creeping jerkily about in all directions on the bark of trees. Nuthatches are the only tree climbers that habitually descend trees headfirst.

HENRY C. JOHNSON FROM NATIONAL AUDUBON SOCIETY

WHITE-BREASTED NUTHATCH (SITTA CAROLINENSIS) DESCENDING TREE TRUNK

Four species occur in North America. The best known is the white-breasted nuthatch (*Sitta carolinensis*), with gray or slate back and wings, a black cap, black eyes on a white face and chestnut under tail coverts. Its nasal song and familiar call of "yank, yank" may be heard at all seasons in woodlands and towns from southern Quebec and northern Minnesota to Florida and Mexico. (The treeless parts of the Great Plains and the deserts are devoid of nuthatches.) During most of the year it feeds on insects, which it seeks on the boles and larger limbs of old trees, but in autumn and winter it feeds on acorns and other nuts and on hard seeds. It makes its nest in a hole in a branch or stump of a tree, often in an empty nesting hole of a woodpecker. The interior contains a bed of dry leaves or the filmy flakes of the inner bark of a fir or cedar, on which the 5–8 whitish, brown-speckled eggs are laid. The red-breasted nuthatch (*S. canadensis*), slightly smaller and with rusty underparts and a black line through the eye, prefers conifer forests of both east and west coasts. The brown-headed nuthatch (*S. pusilla*) occurs in the southeastern U.S., and the pygmy nuthatch (*S. pygmaea*) is found along the middle California coast.

The common nuthatch of the old world (*S. europaea*) is widely distributed, with many local races from England to as far as Siberia and Japan. It has a blue-gray crown and back, buff underparts and chestnut flanks; the cheeks and throat are white and a black line passes through the eye. Like its American counterparts, it is a common visitor in gardens, orchards and parks. The rock nuthatches, *S. neumayeri* and its races and close relatives, nest and hunt among rocks rather than trees; they range from southeast Europe to Israel, Iran and Turkistan. Other less known species of *Sitta* occur in various parts of Asia. No nuthatches are found in South America, Africa from the Sahara southward or New Zealand.

A peculiar genus with a single species, *Hypositta corallirostris*, is confined to Madagascar. The Malay velvet-fronted nuthatch, pink and black, and the deep-blue nuthatch, with a beautiful blue belly, belong to an allied genus, *Dendrophila*, living in India and the Malay countries and islands. The genus *Neositta*, Australian tree runners, is also found in New Guinea, where also the single species of *Daphoenositta* is confined. (HT. FN.)

NUTLEY, a town of New Jersey, U.S., 5 mi. N. of Newark on the Passaic river, 13 mi. W. of New York city, adjoining Bloomfield and Belleville. Founded in 1680 by the Dutch as part of Newark, it was detached in 1812 to become part of Bloomfield. In 1874 it was separated as an independent township and renamed Franklin in honour of William, son of Benjamin Franklin, last royal governor of New Jersey. In 1902 it was renamed Nutley and incorporated as a town. Primarily residential, with many old colonial style homes, it has various industries: textiles, insulators, chemicals, pharmaceuticals, paints, machine tools, radar, telephone and electrical equipment and paper. In the late 19th century it was an authors' and artists' settlement; living there were Frank R. Stockton, author of "The Lady or the Tiger?" and *Rudder Grange*, and Henry C. Brunner. For comparative population figures *see* table in NEW JERSEY: *Population*.

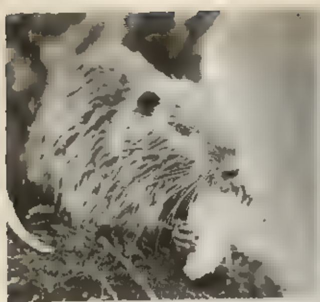
See E. S. Brown, *History of Nutley* (1907). (D. N. A.; M. P. M.)

NUTMEG, the commercial name of a spice representing the kernel of the seed of *Myristica fragrans*, a dioecious evergreen tree that may reach 70 ft. high, found wild in the Moluccas or Spice Islands and extending to New Guinea.

True Nutmeg and Mace.—Nutmeg and mace are mostly obtained from the Moluccas and the West Indies, although cultivation has been attempted with varying success elsewhere. The trees yield fruit in 8 years after sowing, reach their prime in 25 years and bear for 60 years or longer. The stands on the Moluccas thrive in the shade under groves of lofty trees. The fully ripe fruit is about two inches in diameter, of a rounded pear shape, and when mature splits into two, exposing a crimson aril surrounding a single shiny brown seed. When the fruit is collected the pericarp is first removed; then the aril is carefully stripped off and dried, in which state it forms the mace of commerce. The seed consists of a thin, hard shell, enclosing a wrinkled kernel, which, when dried, is the nutmeg. To prepare the nutmegs for use, the seeds are dried in the sun, gradually and with frequent turning, until the kernels will rattle in their shells when shaken. When thoroughly dried the shells are broken and the nutmegs picked out and sorted, the smaller and inferior ones being reserved for the expression of the fixed "oil of mace" that they contain. Oil of mace, or nutmeg butter, is a solid fatty substance of reddish-brown colour, obtained by grinding the refuse nutmegs to a fine powder, which is steamed and compressed while still warm, the brownish fluid that flows out being afterward allowed to solidify. Nutmegs yield about one-fourth of their weight of this substance. It is partly dissolved by cold alcohol, the remainder being soluble in ether. The latter portion, about 10% of the weight of the nutmegs, consists chiefly of myristin, which is a compound of myristic acid with glycerin. Nutmegs, maces and their oils are used as condiments and carminatives. A liniment or ointment made of nutmeg butter has been used as a counterirritant and in treatment of rheumatism. The oils are used to scent soaps and perfumes.

Other "Nutmegs."—The name nutmeg is also applied to other fruits or seeds in different countries. The Jamaica or calabash nutmeg is derived from *Monodora myristica*, the Brazilian from *Cryptocarya moschata*, the Peruvian from *Laurelia aromatica*, Madagascar or clove nutmeg from *Ravensara aromatica* and the California or stinking nutmeg from *Torreya californica*.

NUTRIA (COYPU), *Myocastor coypus*, a large aquatic rodent native to South America. Features that distinguish it from other members of the family Capromyidae are: size (up to 25 lb.); reddish-brown fur; long, round-tipped tail; partially webbed hind toes; short, round ears; and smooth, broad, orange-coloured incisor teeth. These traits have given it the misnomer "South Amer-



DOUGLAS FISHER

NUTRIA FEEDING (MYOCASTOR COYPUS)

ican beaver," but it more closely resembles a guinea pig or an agouti. The mammary glands are peculiarly placed along the sides of the back, an arrangement thought to be an advantage in permitting the young to suckle while the mother is surface swimming. The nutria lives in shallow burrows along the banks of rivers and edges of ponds; it subsists largely on aquatic plants, coming ashore to feed, especially in the evening. It is prolific, producing from two to eight young at a birth, and having as many as three litters a year.

Prime nutria pelts are of some commercial value but require expensive processing. In the late 19th century a high demand for pelts led to the near extermination of the species in Argentina. Raising nutrias in captivity in South America began in 1922 and spread to many other countries. High prices were paid for breeding stock, but the pelts from ranch-raised stock were generally inferior, and these ventures were disappointing. Some nutrias were turned loose, others escaped, and populations became established in the wild. In many countries to which they were imported, France, for example, nutrias became a distinct liability, feeding on cultivated crops, damaging dikes and irrigation ditches, destroying habitats of and competing with other wildlife. They are established in several other European countries and in Canada, and are a problem in parts of the southern U.S. (R. H. MA.)

NUTRITION. All forms of life, plant and animal alike, from simple single-cell organisms to complex mammals, require certain food materials in certain minimum amounts and proportions to ensure an active life and successful reproduction. Nutrition is concerned with what these materials are, how they function, what effects they have when absent or in too plentiful supply, what happens to them when ingested and other related problems. Nutrition might be defined as the science of food and the nutrients in food and their relation to health. Because of this wide scope there has been increasing overlapping with such sciences as biochemistry, enzymology and physiology. In spite of the enormous diversity of living things, each can be said to have two major nutritional requirements: (1) compounds which are sources of energy; and (2) substances whose primary purpose is to fill a structural or functional need. Some of course fulfill both needs. Often what is an absolute dietary essential for one species is without effect in another, for the latter may be able to synthesize it from other materials. In many instances knowledge of the nutrition of one species aids immeasurably in gaining nutritional information about another. For example, the requirement of a microorganism for a given nutrient may make possible the analysis of this compound in foods which are to be consumed by other living organisms.

General Requirements.—All living cells, whether existing as separate entities or as part of a complex tissue, require one or more inorganic substances and some form of carbon and nitrogen. On the other hand, the need for complex exogenous organic compounds is quite different for the various forms of life. Whereas vitamins and proteins are essential for many animal species, plants are without this requirement for they are able to make these out of simpler chemicals such as carbon dioxide, water and ammonia. This difference between forms of life has a tremendous importance, for continuous cycles exist in nature whereby simple compounds of the elements such as carbon and nitrogen are converted into complex molecules by some species; these in turn are used by higher forms where they are again eventually converted to simple compounds. Thus, in the long run, only energy has been expended. Were these cycles to be interrupted for long, life on earth as we know it would cease.

Plants.—Much is known of the requirements of plants for minerals, carbon and nitrogen. As is the case with animals, certain of the elements are required in extremely minute amounts for normal growth and reproduction. These are known as trace elements, a term not to be confused with the word tracers, which refers to isotopes incorporated into compounds to facilitate the tracing of a biochemical pathway. Boron and silicon are examples of trace elements which are needed by some plants but have not been shown to be required by animals. The nutrition of plants has a very important bearing upon nutrition of animals because the latter consume the plants and thereby gain proportionately to the nutritional status of the plants. The importance of this is shown by the fact that the analysis of plants for important nutrients is a constant facet of nutritional research. Furthermore, agricultural research is engaged in improving the food value of crops through plant breeding and nutrition.

Microorganisms.—A fascinating phase of nutritional investigation has been that dealing with the requirements of microorganisms: bacteria, molds and yeasts. As might be expected the diversity of microorganisms makes for a diversity of nutritional requirements which is reflected among species and also among strains within a given species. Some, like the plants, require no complex organic material whatsoever. Nitrogen (usually as an ammonium salt), carbon (as a simple salt such as carbonate) and minerals are sufficient to provide optimum growth and reproduction in such organisms. Others, however, have almost as complex requirements as human beings do. In these cases amino acids, vitamins, carbohydrates and minerals must be made available in chemical forms readily utilized by the organism. So exacting are the requirements of many organisms for certain nutrients that in the absence of any particular one there will be no growth. If inadequate amounts are provided, the growth will often be proportional to the amount present. This forms the basis of several important tools for biochemical and nutritional research. One of these is the microbiological assay developed by E. Snell and F. Strong. In this procedure all but one of the nutrients necessary for rapid growth are furnished to an organism such as *Lactobacillus casei*, found in cheese. When the missing factor is furnished in some suitably prepared extract of a natural product, the increased growth that results is a measure of the amount of the compound present in a readily available form. Comparison of this response with that obtained when known amounts of the factor are present give a fairly exact estimate of the amount of the substance in the natural product. Such assays came to have widespread use because of their simplicity, accuracy and rapidity.

Microorganisms also aid in the understanding of the nutrition and biochemistry of higher animals in another way. They readily lend themselves to investigations which deal with the actual pathways of synthesis and degradation of important nutrients and biologically important compounds. Extensive studies, notably by E. L. Tatum and co-workers, have been made on organisms which have been damaged by X-rays. Such organisms have lost the ability to carry out one step in a series of biochemical reactions. By proper techniques it is possible to isolate the affected ones and determine where such a metabolic lesion occurs and what its exact nature is. Such damage is usually reflected in the need for an additional nutrient not ordinarily required. In a sense an almost unlimited number of mutants of a given organism can be produced which differ only in that each has a special "dietary" requirement.

Although it is usual to think of higher animals in terms of the individual, such is not strictly possible from a nutritional standpoint. The reason is that the intestinal tract supports a flourishing population of microorganisms which have their own nutritional requirements, produce various important nutrients themselves and also degrade other nutrients. It is difficult to assess the importance of these uninvited guests on the nutritional status of the host, however, except in certain instances. For example, the use of antibiotics and sulfa drugs is known to have definite effects on the intestinal flora which may influence the amount of certain vitamins available to the patient. In studies with animals born and raised under germ-free conditions, J. A. Reyniers and co-workers showed that good growth and reproduction are not dependent upon the intestinal flora.

Human and Animal Nutrition.—The nutrition of the more

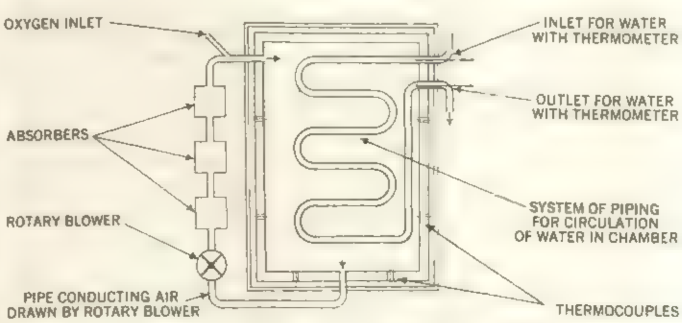
complex forms of life, the higher animals and humans, differs from that of the plants and microorganisms in several important aspects: First, all higher animals require a number of preformed complex organic compounds in their diet for bare survival, let alone optimum development and reproduction. Second, the requirements that must be met are not only those of a diversity of cells but also those of complicated tissues. Third, there is absolute dependency upon plants and microorganisms for dietary requirements. Fourth, higher animals have a greatly added caloric requirement to meet the needs imposed by muscular activity. In addition to these and other differences, the higher animals possess such additional traits as appetite, habits and idiosyncrasies that influence not so much their requirements as the problems of meeting those requirements adequately.

Caloric Requirements.—The fundamental requirement of the cell, and therefore of the animal as a whole, is for calories. Without a source of energy, the capacity to do work would be lacking and life would stop. Ordinarily, this need is satisfied by the consumption of sufficient caloric foodstuffs. In conditions such as starvation, the need for calories continues but the source now is the body's own reserves of fats, carbohydrates and, to some extent, proteins. Obviously, there comes a time when these sources are exhausted and death ensues. During the period immediately prior to death, it is found that the animal becomes progressively less active in order to economize on the expenditure of calories.

Energy must be provided to satisfy a number of different needs. In the adult the most basic one is for maintenance of the *status quo* of the body exclusive of voluntary muscular work and other additional energy-consuming functions. Many of the processes which contribute to this basic need are easily overlooked, for they include the maintenance of body temperature, breathing, heart action, gastrointestinal activity, muscle tone and many reactions which are involved in the chemical syntheses and degradations constantly going on in the tissues. One of the most important of the nonbasic functions is that of voluntary muscular work. The size of the caloric demand for this function is governed by the activity of the individual. Energy must also be supplied for growth in children and for women during pregnancy and lactation. The recommended caloric intakes for men, women and children under various conditions and the recommended intakes of certain other nutrients have been tabulated by the Food and Nutrition board of the National Academy of Sciences–National Research council (*see* Table).

In order to determine either the caloric requirement or the amount of food necessary to meet this need, it is essential to know the caloric value of the energy-yielding components of food. This value can be established by completely burning a pure sample of fat, carbohydrate or protein in a device known as a bomb calorimeter. During this process all organic matter is converted to carbon dioxide, water and nitrogen oxides, and the energy liberated is calculated from the amount of heat evolved. The number of calories per gram of material obtained by this method, however, is above that available to the animal because of incomplete absorption of the compounds from the intestine and also because of incomplete metabolism of the protein which results in the loss of calories through the urinary excretion of urea, uric acid and related compounds. The losses can be measured and subtracted from the values derived in the bomb calorimeter. When this is done it is found that the caloric values of fat, carbohydrate and protein are nine, four and four calories per gram respectively. To calculate the caloric content of a food it is only necessary to multiply the per cent of each of the proximate principles (fat, carbohydrate and protein) by its respective caloric value and add the products together.

The use of a direct animal calorimeter enables the determination of not only the caloric values of foods, but the extent and degree of metabolic activity of the subject as well. The subject is enclosed in a special chamber or calorimeter so devised that all the heat given off by the subject can be directly collected and measured (*see* figure). In order that there be no escape of the body heat to the environment, the double copper walls of the chamber are fitted with elaborate electrical equipment that permits such a delicate balance that heat can neither pass out of nor into the chamber. In order to measure the heat given off by the subject, a current of cold water is circulated within the box in continuous piping. If the temperature of the incoming and outgoing water is carefully measured and if the quantity of water passing through



DEVISED BY W. O. ATWATER, F. B. ROSA AND F. G. BENEDICT

SCHEMATIC DRAWING OF RESPIRATION CALORIMETER

also is known, the heat lost by radiation and conduction by the subject in a given time can be determined. As part of the heat lost, amounting to about one-fourth of the whole, is eliminated by the subject in the form of water vapour, this loss is determined by absorbing the lost water in sulfuric acid and weighing the acid to measure its gain in weight.

This method of direct calorimetry is very accurate and reliable, but the method is difficult and the apparatus is very liable to get out of order. In addition to this direct measurement of the heat output, the metabolic activity of the subject can be calculated from a determination of the amount of carbon dioxide given off and the amount of oxygen utilized by the subject in a given period. This method of indirect calorimetry can be carried out simultaneously with the direct method and serve as a check upon it. The calorimeter chamber in which the subject is enclosed is gastight and the air is circulated through a gastight absorbing system by means of a rotary blower. The carbon dioxide given off is absorbed by means of soda lime, the amount absorbed being determined by weighing the soda lime at the beginning and the end of the experiment. The carbon dioxide-free air is returned to the chamber after the deficiency in oxygen, which is approximately determined by reduction in volume, has been corrected by adding oxygen from a cylinder. The amount of oxygen used during the experiment is determined either by metering the amount of oxygen passed in or by weighing the cylinder before and after the experiment. The heat lost by the subject can be determined from the amount of oxygen used. The caloric value of a litre of oxygen used in tissue combustion has been determined. This value varies with the carbon dioxide-oxygen ratio, called also the respiratory quotient (R.Q.), from 4.795 cal. with an R.Q. of .713, which is held to represent the combustion of fat alone, to 5.058 cal. with an R.Q. of 1.00, which is accepted as representing the combustion of pure carbohydrate by the tissues. The two methods of direct and indirect calorimetry have been found to give almost identical results.

A portable apparatus that measures the energy expenditure of subjects engaged in work was designed by N. Zuntz and later much simplified by C. Douglas. When using the simplified apparatus, the subject, wearing either a mask or special mouthpiece (with nose clip) fitted with two one-way valves, breathes into a gastight bag carried on his back. At the end of the experiment the air collected in the bag is measured by passage through a meter, a sample of the expired air is analyzed in the Haldane gas analysis apparatus, and the amount of carbon dioxide and oxygen present is determined. As the composition of the atmospheric air is known, it is easy to calculate how much carbon dioxide the subject excreted and how much oxygen he utilized in a given time; the caloric values can be determined as above. In order to relate the carbon dioxide output and oxygen utilization to the nonprotein moiety of the food the protein metabolized during the period of the experiment is determined from the nitrogen output in the urine. For every gram of urinary nitrogen derived from protein 8.45 g. of oxygen are required and 9.35 g. of carbon dioxide are given off. Hence, to determine the nonprotein utilization the appropriate amounts of carbon dioxide and oxygen are deducted from the total amounts. As the amount of nitrogen excreted during the period of examination is minute, it is usually ignored in practice. (*See* also CALORIMETRY.)

When the alterations of the gaseous metabolism are considered they are commonly referred to variations from the so-called basal metabolism. The basal metabolism may be defined as that of a subject lying comfortably at rest in a warm bed and in the postabsorptive condition; *i.e.*, about 12 to 15 hours after the last meal. With the subject in such a condition the metabolism reaches its lowest level. It has been estimated that functional activities of the various organs may account for about 25% of the resting metabolism (thus the activity of the heart for about 3.6%, respiratory movements for about 10% and the kidneys for about 5%).

This basal metabolism is shown to be high in childhood; as adolescence is reached it falls to a level which is more or less uniformly maintained until about the age of 50. Thereafter the decline is steady although small. The basal metabolism is also influenced by the sex of the subject, the nature of the food consumed and environmental conditions like temperature, climate, etc.

Differences in human weight, height and sex also complicate calculations of energy assessments. As a means of overcoming this difficulty, E. F. and D. Du Bois proposed the extensively used formula (height × weight × a constant) to obtain basal metabolism values in terms of caloric output per square metre of body surface area. In the early 1960s the caloric allowance for differences in size given by the Food and Nutrition board for persons neither over- nor underweight was calculated on the basis of weight. The assumption was made that 25% of the energy expenditure was independent of body weight and 75% was directly proportional to body weight.

Components of Nutrition.—Carbohydrates, fats and proteins form the major portion of the diet, while minerals and vitamins are present in smaller quantities. All are important and many have special functions as will be seen below. (*See* CARBOHYDRATES; OILS, FATS AND WAXES; PROTEINS; VITAMINS).

Until R. Schoenheimer and D. Rittenberg demonstrated otherwise, most of the body constituents such as proteins and fats were considered to be stable in the sense that they were not in equilibrium with ingested food components. The latter were thought either to undergo degradation or, if incorporated in body constituents, to remain there indefinitely. There was no adequate way to study this problem before the advent of isotopes, because there was no way of distinguishing an ingested compound or its parts from like ones already present in the body. By synthesizing compounds which contained an isotope of one of the atoms in the molecule, it was possible to follow the exact fate of the compound by making suitable isotope measurements. Such experiments have shown beyond doubt that there is a constant equilibrium between ingested substances and identical ones which have been incorporated into the body. This concept of a "dynamic state of body constituents" had profound effects on the understanding of biochemistry and nutrition.

Enzymes.—Many enzymes are involved in biochemical reactions that are concerned with the removal or addition of water between molecules while others are concerned with joining or splitting the bonds between atoms within a molecule. (*See* ENZYMES.) The process of digestion, for example, involves the addition of water (hydrolysis) to complex molecules with the formation of their simple integral parts. On the other hand, the metabolism of these simpler molecules may involve either their reincorporation into other complex compounds or their conversion to other simple molecules. It is believed that almost every reaction in the body is mediated by an enzyme which is specific for that particular reaction. Many of the enzymes had been isolated by the 1960s and in many cases had also been crystallized. One of the most interesting properties of enzymes is their high degree of activity under very mild conditions. Similar reactions carried out by chemical means alone would require in many instances drastic conditions and long reaction times. All enzymes discovered had been found to contain mainly protein, and it was also shown that they are not immune from the "dynamic status" referred to previously. Many toxic materials are known to inactivate enzymes, and this action is believed to be the basis of their toxicity. Numerous modern drugs also function by virtue of some effect on one or more enzyme systems. Indeed, such sought-for activity forms the basis of research in many fields such as cancer where the arrest of specific processes is essential.

Carbohydrates.—These compounds are present in most foods in the form of sugars known as disaccharides, such as cane sugar, and polysaccharides, such as starch. When ingested, they must be converted into monosaccharides, or simple sugars, before they can be absorbed. Ptyalin, an enzyme found in saliva, is able to effect some hydrolysis of starches, but the main agents which cause the hydrolytic breakdown of the carbohydrates are amylase, maltase, sucrase and lactase, which attack starches, maltose, sucrose and lactose (milk sugar), respectively. The nutritionally important simple sugars—fructose, glucose and galactose—which are thereby formed are absorbed and are made available via the blood stream to the cells of the various tissues. Here the first step in their

utilization involves enzymatic reactions which result in the formation of phosphorylated sugar. The sugar phosphates then either are converted to glycogen or undergo a series of reactions which lead eventually to the formation of carbon dioxide and water. The elucidation of these reactions by such workers as A. Harden and W. Young, C. F. and G. T. Cori, G. Embden, O. Meyerhof, H. Krebs and A. Szent-Györgyi was of tremendous importance to the fields of biochemistry and nutrition. (*See* also KREBS CYCLE.) It was absolutely established through isotope studies that some of the carbon present in the sugars can be recovered in the fat, protein and other important compounds in the body.

The proper utilization of carbohydrate is essential for health. Insulin (*q.v.*) is necessary to carry out the initial phosphorylation of glucose. When insulin is deficient, as in diabetes mellitus, the glucose concentration in the blood rises and some of the sugar is lost in the urine. Another hormone, adrenaline (epinephrine), which is produced by the adrenals, causes the breakdown of carbohydrate stored in the liver and muscles as glycogen. It is this source of energy which is called upon for immediate needs. About 100 g. of carbohydrate per day are necessary for the prevention of ketosis in human adults.

Fats.—When fats are eaten, relatively little happens until they reach the intestine. There they are emulsified and undergo extensive enzymatic hydrolysis by lipase to form mono- and diglycerides and fatty acids. The precise manner in which these products are absorbed was still undetermined in the 1960s. Ordinarily most of the fat upon being absorbed enters the lymphatic system and is present as an extremely fine emulsion known as chyle, which enters the blood stream through the thoracic duct. The small droplets of fat (chylomicrons) then appear to undergo a process of partial dissolution brought about by the action of an enzyme, lipoprotein lipase, found in blood and tissues. Further metabolism occurs within the cells.

Since the early studies of F. Knoop the mechanism by which fatty acids are degraded had been postulated to proceed by removal of two carbons at a time, but definitive proof of this was not obtained until much later. Through the research of A. L. Lehninger, F. A. Lipmann, F. Lynen, D. Green and others it became known that the fatty acids react to form phosphate esters which in turn react with coenzyme A (a derivative of the vitamin pantothenic acid) to form coenzyme A derivatives. In this form they undergo a series of enzymatic transformations to yield at intervals the coenzyme A derivatives of the next lower fatty acid and of acetic acid. This continues until the acid is degraded. The acetic acid-coenzyme A molecules may react with a carbohydrate derivative, oxaloacetate, and be converted to carbon dioxide and water, or form "ketone bodies." The latter are greatly increased in diabetes. By means of fats labeled with radioactive carbon it was definitely shown that fats can be converted to carbohydrates and proteins. Aside from serving as a source of energy, fats act as insulating material against cold and mechanical shock. They also serve as carriers for fat-soluble vitamins. The normal adult human male consumes about 150 g. of fat per day. As far as is known this amount is not necessary; however, it is easy to obtain part of the daily caloric requirement in the form of fat because of its higher caloric value per gram.

Essential Fatty Acids.—Historically, this group of nutrients is comprised of linoleic, linolenic and arachidonic acids, all of which are polyunsaturated. George O. Burr and M. M. Burr first demonstrated that without at least one of these acids in the diet the rat failed to grow, developed scaly skin and necrosis of the tail, and eventually died. Considerable study has shown that these acids may be of importance in atherosclerosis because they are effective in lowering the cholesterol concentration in the serum of man and animals. Such an effect often can be achieved by the inclusion in the diet of liberal quantities of maize, safflower or similar vegetable oils that are rich in essential fatty acids, mainly linoleic. An appreciable portion of the cholesterol of blood serum occurs as the ester of this acid. In the early 1960s linoleic and arachidonic acids were shown to be necessary in animals and human infants. (*See* also CARBOXYLIC ACIDS; CHOLESTEROL.)

Proteins.—Although available as a source of calories, dietary protein functions chiefly by supplying amino acids for the maintenance and synthesis of body proteins. When ingested, protein is not absorbed as such but is first converted to peptides and then amino acids. This conversion begins in the stomach through the action of the enzyme pepsin (*q.v.*), which is effective in the acidic condition found there. The rest of this degradation is carried out in the intestine by the enzyme trypsin. Both of these enzymes also occur in an inactive form or zymogen and are converted to the active form when the need arises. Once the amino acids are formed they are absorbed and transported via the blood stream to the various tissues. Here they may be incorporated into tissue proteins or undergo various metabolic degradations. Since the structures of the amino acids are on the whole dissimilar, these reactions are multifold and usually quite specific. The amino group of the acid may be transferred to a nonamino acid by means of an enzyme of the class known as transaminases. One of the B-complex vitamins, pyridoxine, plays a role in this type of transformation. The ultimate fate of the amino acids is metabolism to water, carbon dioxide, ammonia, urea, uric acid and related compounds. In species which have access to an abundant water supply, urea is the chief urinary nitrogenous excretory product, while in those with limited water supplies, uric acid is more important. When the amount of nitrogen excreted in the urine, feces and other excretory products such as perspiration equals the amount of nitrogen ingested, the subject is in nitrogen equilibrium. During growth, the output of nitrogen is smaller than the input; the reverse is true in starvation. The amount of protein ingested has an important bearing on the nitrogen balance.

Not all proteins are adequate for normal nutrition. This stems from the fact, as found notably by W. C. Rose, that of the approximately 20 naturally occurring amino acids, only eight are necessary in the human diet since the others can be synthesized by the body. This means that if a protein contains the essential amino acids in adequate amounts it is a complete protein and can satisfy the needs of the body when consumed in normal quantities. Incomplete proteins may be used to fortify one another in such proportions that they supply sufficient quantities of the amino acids. H. Borsook found that for optimum utilization the amino acids should be ingested simultaneously. An interesting interrelationship between tryptophan, one of the essential amino acids, and nicotinic acid, the pellagra-preventing vitamin, was uncovered. Many of the details were known by the mid-1960s, and it was definitely established that an interconversion between these compounds can take place in the body and as a result the intake of one can affect the apparent effectiveness of the other when the latter is in short supply. Thus, in the normal adult human 60 mg. of tryptophan furnishes the equivalent of 1 mg. of niacin.

Inorganic Materials.—The body requires a constant replenishing of the minerals and electrolytes that are excreted from the body in various forms. Among those that are needed by most species are calcium, magnesium, iron, iodine, phosphorus, sodium, potassium and chlorine. Whereas it is recommended that the adult male take in 0.8 g. of calcium per day, 10 mg. of iron are sufficient. In many instances with animals the need for trace elements has been shown. These include zinc, copper, cobalt and manganese, and the amounts required per day when calculated on the basis of humans is far below that of iron. Of interest is the fact that less than 0.0001 mg. of cobalt in the form of vitamin B_{12} is necessary to keep pernicious anemia patients normal. This vitamin is the only one known to have a metal as part of its molecule. On the other hand, metals are known to play a role in many enzyme reactions. Copper, for example, is necessary for the oxidation of ascorbic acid (vitamin C) by the enzyme ascorbic acid oxidase, while magnesium is essential for several enzymatic steps in the metabolism of carbohydrate. Phosphorus plays an important role in the metabolism of many compounds. In addition it is a major constituent of bone and teeth.

As a result of the different metabolic processes that take place in the tissues there is a constant production of acid, chiefly from sulfur and phosphorus, which must be neutralized by basic ions containing sodium and potassium and probably also calcium and magnesium. The kidney for the most part regulates in a very

selective fashion the output of these various inorganic constituents. It must not be imagined, however, that the body can completely protect itself from excessive salt loss, a loss so great that it may give rise to symptoms of a serious character. Thus it has been shown that men who, in the course of their work, are exposed to high environmental temperatures with consequently much sweating are very liable to a form of cramp. Further the cramp is frequently exacerbated where the men drink freely of water to allay their thirst. It has been found that the condition is due to an excessive loss of sodium chloride from the body carried away in the sweat and that the condition may be cured or prevented by taking salt tablets.

Although five-sixths of the total mineral matter of the body is found in bone, and in spite of the fact that bone has all the appearance of being firm and resistant, the evidence available shows that the bony structures must be regarded as active storehouses of mineral matter. When the need arises the body as a whole can draw upon the bones for constituents such as lime and phosphates. Under certain conditions the bones may give up so much of their mineral matter that they become soft and can no longer function as an effective framework.

The other one-sixth of the mineral constituents found in the body are not distributed uniformly throughout the remainder of the tissues. As regards this varying distribution of salts in the tissues and the blood, A. B. Macallum, in his study of paleochemistry, produced some interesting evidence in favour of his view that the present composition of the blood plasma, insofar as its inorganic constituents are concerned, is probably identical with that of the sea water just before the Cambrian period and that the salt concentration in protoplasm represents conceivably the salt concentration of the primeval ocean in which life first appeared. At any rate the curious ratio of potassium and calcium to sodium that is characteristic of protoplasm is reflected in the salt relationship in water drawn from Pre-Cambrian formations.

Water.—Because water forms about 60% of the body weight of man, it obviously plays an important part in metabolism. The whole series of chemical actions that are intimately related to the life of the living organism, animal or vegetable, are ultimately referable to changes that take place in solution. It has been conclusively shown that the younger the animal the richer it is in water. It has also been found that the fatter the animal the smaller the percentage amount of water present.

Studies with heavy and radioactive water have shown that exchange occurs between ingested water and metabolically derived water in the cells; much information concerning the extent and rate of exchange has been derived from these studies. Some water in cells is tightly associated with proteins and other cellular constituents and is referred to as bound water. Although some forms of life require little water, none can exist without any.

Vitamins.—These organic compounds are important components of nutrition. For detailed information about vitamins, *see* the article under that title.

See also BIOCHEMISTRY; DIGESTION. Daily food allowances and diet planning are discussed in DIET AND DIETETICS. Deficiency diseases and other problems are discussed in MALNUTRITION. *See* also references under "Nutrition" in the Index.

NUTTALL, GEORGE HENRY FALKINER (1862–1937), biologist and founder of the Molteno institute for research in parasitology at Cambridge, Eng., was born in San Francisco, Calif., on July 5, 1862. Graduating M.D. at the University of California, Berkeley, in 1884, he joined Johns Hopkins university, Baltimore, Md., in 1885. During 1886–99 he studied zoology, botany and hygiene, mostly in Germany, developing his eventual interest in parasitology. He was appointed lecturer in bacteriology and preventive medicine at Cambridge university in 1900, and elected in 1906 to the newly founded Quick professorship of biology, holding this until 1931. He founded the *Journal of Hygiene* in 1901 and remained editor until his death; in 1908 he founded *Parasitology* and was chief editor until 1933. In 1919 he raised funds for the erection of an institute of parasitological research in Cambridge—the Molteno institute. Nuttall's work covered a very wide field; he wrote almost 200 papers on bacteriology, serology, hygiene, tropical medicine and parasitology. He made pioneer experiments on life under aseptic conditions, founded the study of humoral immunity and work on precipitin reactions. He acquired British nationality on going to Cambridge.

His classical monograph, *Blood Immunity and Blood Relationship*, appeared in 1904. Later he studied diseases transmitted by ticks and with W. R. Hadwen discovered the curative properties of trypan blue for piroplasmosis. *Ticks, a Monograph of the Ixodoidea* (with C. Warburton and L. Robinson) appeared in parts from 1908. He died in London Dec. 16, 1937. (ED. HE.)

NUTTALL, THOMAS (1786–1859), British-U.S. naturalist, was an expert on North American flora and described many new genera and species of plants. He was born on Jan. 5, 1786, at Long Preston, Yorkshire. After serving seven years as an apprentice printer, he emigrated to the United States in 1808. Benjamin S. Barton (*q.v.*) encouraged and assisted him in his scientific career. Nuttall's expeditions included those to the Missouri river (1810–11), Arkansas territory (1818–20), and the Columbia river and Hawaii (1834–36). He was lecturer on natural history and curator of the botanic garden at Harvard university from 1825 to 1834. His publications include *Genera of North American Plants, and a Catalogue of the Species, to the Year 1817* (1818), describing genera and enumerating species; and *The North American Sylva* (1842–49). Nuttall's *A Manual of the Ornithology of the United States and of Canada* (1832–34; further editions in 1840, 1891, 1896 and 1903) was the first work of moderate size and price on American birds. In 1842 Nuttall returned to England. On Sept. 10, 1859, he died at Nut Grove hall, Lancashire.

See biography and list of works in *Leaflets of Western Botany*, vol. ix, pp. 32–42 (1959). (J. W. TT.)

NUWARA ELIYA, a town and district of Central province, Ceylon. The town, administrative centre of the district, is situated about 6,200 ft. above sea level in the heart of the picturesque central highlands, 48 mi. S.S.E. of Kandy and 110 mi. E. of Colombo by road. Pop. (1953) 14,405. It lies in a pleasant hollow only 2 mi. S. of Ceylon's highest mountain, Pidurutalagala (8,281 ft.). Nuwara Eliya is a hill station with a refreshing climate. It is the headquarters of the Ceylon Fishing club and has a beautiful setting. The mean monthly temperature varies from 13° C. (56° F.) in February to 16° C. (61° F.) in May; these figures, however, conceal a considerable daily range, and frost is not unknown at night.

NUWARA ELIYA DISTRICT (area 474 sq.mi.) had a population (1953) of 325,254. Much of it is under tea plantations. Indian Tamils form the main population group. (B. H. F.)

NUX VOMICA, a poisonous drug, consisting of the dried ripe seed of *Strychnos nux-vomica*, a tree (family Loganiaceae) indigenous to most parts of India and found also in Burma, Thailand, Indochina and north Australia. The drug was once used as a bitter tonic and stimulant in humans and is still employed in this way in animals.

The tree is of moderate size, with a short, thick, often crooked stem and ovate entire leaves, marked with three to five veins radiating from the base of the leaf. The flowers are small, greenish-white, tubular and arranged in terminal clusters. The fruit is the size of a small orange and has a thin hard shell, enclosing a bitter, gelatinous white pulp in which from one to five seeds are vertically embedded. The seed is disk shaped, about one inch in diameter, and one-fourth inch thick, slightly depressed toward the centre, and in some varieties furnished with an acute keellike ridge at the margin. Externally, it is grayish-green and satiny from a coating of appressed silky hairs. Internally it consists chiefly of horny albumen, which is easily divided along its

outer edge into halves by a fissure, in which lies the embryo. The latter is about three-tenths inch long and has a pair of heart-shaped membranous cotyledons.

The chief constituents of the seeds are the alkaloids strychnine (*q.v.*) and brucine, each of which constitutes from 1% to 2% of the dried seeds. The two have similar pharmacological actions, though brucine is much less active.

NUYTSIA, a genus of the mistletoe family (Loranthaceae) named after an early Dutch voyager, Peter Nuyts. Its single species, *N. floribunda*, is the Western Australian Christmas tree. It grows to a height of about 30 ft. and in December (summer in Australia) the massed golden-orange flowers make it a conspicuous feature of the sand heaths and eucalyptus forests of southwestern Australia from the Murchison river to King George's sound. *Nuytsia* is a semiparasite on the roots of native trees and shrubs, depending on its host only for mineral elements; containing chlorophyll, it is able to manufacture its organic food by photosynthesis. Around Perth many trees have been spared and are to be found in suburban parks and gardens. Cultivation is difficult, but some gardeners have grown seedlings successfully by allowing the roots to parasitize those of a grass such as Bermuda grass (*Cynodon dactylon;* in Australia called couch grass) in the early stages of growth. (J. W. Gr.)

NUZI. The city of Nuzi was located at present-day Yorgan Tepe, 13 km. S.W. of Kirkuk in the Kirkuk *liwa* of Iraq. It lies in the plain between the mountains of Kurdistan and the Little Zab and Khassa Shai rivers. Twelve levels of habitation were found at Yorgan Tepe during the excavations undertaken by the American Schools for Oriental Research, Harvard University museum and the University of Pennsylvania museum in the years 1925–31. Levels xii–vii contained material of the "protohistoric" and "protoliterate" periods; level ii, the Isin-Larsa period; and level i, the Nuzi period proper. The remains on the surface of the mound were of the Roman, Parthian and Sasanian periods. During the Akkadian period the site was known as Gasur. During the 15th and 16th centuries B.C., Nuzi was an important administrative centre.

The site has produced many specimens of great value for the study of Hurrian ceramics and glyptic art. The palace, rebuilt over the centuries, and private homes contained over 4,000 cuneiform tablets. The tablets are written mostly in Akkadian, the *lingua franca* of the period, but most of the personal names are Hurrian and the Akkadian used often contains Hurrian loanwords and shows strong Hurrian influence. From these tablets and those of nearby Kirkuk, an insight into specific Hurrian family law and societal institutions has been possible. Among these may be noted: fratriarchy; the adoption of a son-in-law when the only child is a daughter; inheritance by possession of the testator's house gods; inalienability of property and consequent fictive adoption; providing of a concubine to the husband by the childless wife without sacrifice of her position, etc. This Nuzi material has clarified many difficult passages in the contemporary patriarchal narratives of Genesis. The Hapiru (identified by many with the Hebrews) are mentioned in Nuzi texts in a servile role. After the Nuzi period, the site remained essentially uninhabited for over a millennium. *See* also HURRIANS.

NYACK, a village of Rockland County, New York, U.S., on the west bank of the Hudson River (which there expands into Tappan Zee, 3 mi. [5 km.] wide), 14 mi. (23 km.) above New York City. There is a ferry to Tarrytown, nearly opposite. With the adjacent villages of Upper Nyack, South Nyack, Central Nyack, and West Nyack, the population exceeded 11,000 in 1960. The industries include shipyards, machine shops, and factories. Permanent settlement dates from around 1700. Nyack was incorporated in 1833 and named after a tribe of Algonkin Indians. For comparative population figures *see* table in NEW YORK: *Population.*

NYAKYUSA, a Bantu-speaking people of Rungwe district, Tanganyika (Tanzania), immediately north of Lake Nyasa. Their country comprises alluvial flats near the lake and the mountainous country beyond for about 40 mi. In the 1960s their growing population was more than 230,000. Formerly consisting of six groups of chiefdoms of basically similar culture, they are now invariably known as Nyakyusa (the name of the group inhabiting the lake plains) as a result of modern administrative unification. Bananas are the traditional staple food, augmented with corn, millet, beans and some milk. Rice and coffee have become the principal market crops and, combined with the earnings of labour migrants, are the basis of the modern economy.

Traditionally the Nyakyusa lived in age-villages that may be unique human phenomena. Each village comprised men of about the same age with their wives and children. Boys left home at about the age of ten and lived in a new hamlet apart from their fathers and elder brothers. In due course, the new hamlet became an autonomous village with its own headman, and area of arable land and pasture. A village died as its founders died in old age. A number of villages comprised an independent chiefdom of a few thousand people. The chief had two senior wives and the eldest son of each succeeded to a half of the chiefdom. Succession occurred when the sons were about 30 years old and before their father reached old age. At that time their commoner contemporaries established their hamlets as new villages and chose their headmen. The old chief retired, his old headmen became mainly ritual leaders and the old villages might even shift off their land to make room for the villages of their sons. With modern land shortage the older men are no longer willing to shift and new age-villages seldom become established now.

NYAMWEZI, the Bantu-speaking inhabitants of a wide area of the western region of Tanganyika (Tanzania); their growing population was estimated at 400,000 in the 1960s. They form (together with the Sukuma people, who numbered about 1,000,000) the Sukuma-Nyamwezi language group. Several other peoples, although differing somewhat from the Nyamwezi in language, customs and way of life, have sufficient in common to be included in this group of tribes. The Nyamwezi live mainly in the Tabora, Nzega and Kahama districts.

Other tribes in the group include the Sumbwa (about 70,000, mainly in Kahama), the Kimbu (about 16,000) and the Bende (about 10,000). In some regions animal husbandry is limited by tsetse fly infestation, but these peoples have more than 700,000 cattle; there are also about 425,000 smaller livestock. In addition, the Nyamwezi grow rice, peanuts and sunflower seeds as their main cash crops. These mixed farmers also raise cotton for trade, but not in important quantities.

Tabora, capital town of the Nyamwezi, was the most important pre-European centre in this part of Africa. Arab traders settled there and explorers passed through; as porters, the Nyamwezi became the best-known tribe of east Africa. Although most tribes in the Nyamwezi cluster are matrilineal, the Sukuma follow patrilineal succession and practise leviratic marriage (*see* MATRILINY; LEVIRATE); their clan system has lost much in importance and the rules of exogamy are based on blood relationships rather than on clan tabus. The people of this tribal group have an extensive folklore and are enthusiastic and versatile musicians, singers and dancers. They are famous as practitioners of these arts and have formed a great number of secret societies, many of them relatively harmless (*e.g.*, snake charmers, porcupine hunters) and a few not so harmless. Ceremonies are performed to initiate novices into these societies, but puberty initiations and circumcision are not performed. *See* also TANZANIA, UNITED REPUBLIC OF; BANTU (INTERLACUSTRINE).

NYASA, LAKE, the southernmost and third largest of the Great Rift Valley lakes of east Africa, lies in a deep trough en-

tirely within Nyasaland, its northern and eastern shores forming much of the boundary with Tanganyika and Portuguese East Africa (Mozambique). With a length, in a general north-south direction, of 360 mi., and a width varying from 10 to 50 mi., its area is 11,600 sq.mi. The surface is 1,550 ft. above sea level, and the depth increases to 2,220 ft. toward the northern end, where the forested Livingstone mountains to the east and the Nyika plateau and Vipya mountains to the west (all between 6,000 and 8,000 ft.) fall steeply down to the lakeshore.

Away from the influence of coastal features, which continue beneath the surface, the bottom of the lake is regular and consists of mud. A fresh southeasterly wind (the *mwera*) prevails from May to August, causing steep, short seas, and the coastline offers little shelter. In 1946 a 370-ton vessel, the "Vipya," was overwhelmed in a storm with heavy loss of life. There are few settlements on the eastern shore but near it, halfway up the lake, is Likoma Island, a mission headquarters and site of an imposing Anglican cathedral (completed 1911). On the heavily populated Malawi shore there are government stations at Fort Johnston, Kota Kota, Nkata Bay and Karonga.

The water, fresh and potable, is derived largely from the area of high rainfall in the north. There are 14 perennial rivers feeding the lake, the largest being the Ruhuhu, but the sole outlet is the Shire river (*q.v.*) in the south, a tributary of the Zambezi. The lake has a seasonal rise and fall of about 3 ft., and also a long-period variation. Between 1915 and 1935 outflow was negligible and the lake rose 18 ft. A degree of stabilization of the lake, as well as hydroelectric power and irrigation, was envisaged in the Shire Valley scheme (1955), but this fell into abeyance. A feature of Lake Nyasa is the lake fly, which hatches in clouds large enough to obscure the horizon.

A passenger and cargo vessel "Ilala II," operated by the Nyasaland Railway company, makes three round voyages a month, leaving from Monkey bay, headquarters of the lake services. Cargo is also carried by two other vessels and by tugs with barges. Cotton, rice, rubber, tung oil and peanuts (groundnuts) are shipped to the only railhead at Chipoka, in the south, whence the railway connects through Limbe to Beira, Mozambique. Passenger and cargo traffic increased after World War II, and the former federal government of Rhodesia and Nyasaland improved navigation and harbour facilities.

Commercial fisheries exist at the southern end of the lake, thriving chiefly on *Tilapia*, which is sun dried for African consumption. African fishing is on a subsistence basis. The total annual yield is estimated at 7,000 tons. Of about 200 species of fish recorded by the Fisheries Research laboratory at Nkata Bay, about four-fifths are endemic, being isolated from the Zambezi fauna by the Murchison falls.

The existence of Lake Nyasa was first reported by a Portuguese, Caspar Boccaro, in 1616. David Livingstone (*q.v.*), with John Kirk, reached it from the south in 1859 and was told by the Yao people that its name was "Nyasa" (Nyanja), which describes any mass of water. The first steamer on the lake was the "Ilala I," carried in pieces and reassembled on the shore in 1875 by Scottish missionaries.

Until the end of the 19th century the lake was infested with Arab slave traders, whose influences are seen in the fleet of Arab-type dhows. Three small gunboats, brought to the lake in 1893, helped to establish order. The first shot of World War I between British and German forces was fired on Lake Nyasa when the S.S. "Guendolen" disabled beyond repair the German gunboat "Hermann von Wissmann" on her slipway at Sphinxhaven (Liuli) on the Tanganyika side. (R. T. BA.)

NYASALAND was the name of a British protectorate in east-central Africa, which on becoming an independent member of the Commonwealth of Nations in 1964 was renamed Malawi (*q.v.*). The present article deals with the history of this country up to independence.

The first foreigners known to have discovered Lake Nyasa (Malawi) and to make firm contact with the Bantu peoples on its shores were Arab slave traders who established a base on the lake in the early 19th century and carried the slave trade westward into central Africa. When David Livingstone reached Nyasaland in 1859 he was horrified by the barbarities of the trade, stirred the conscience of his fellow countrymen with his descriptions, and urged the churches to send out missionaries to heal what he called the "open sore of the world." The first of these arrived in 1861 but it was not until 1875 that missionaries of Scottish Churches were able to establish themselves in the country. At their request the African Lakes Company was formed, supplying the missions and providing "legitimate commerce" as an alternative to the slave trade. Both the missionaries and the company came into conflict with the slave traders. The British government was reluctant to take on more responsibilities, though in 1883 a British consul was sent out to the area, accredited to "the kings and chiefs of central Africa." In 1891, following an attempt by the Portuguese to extend their power inland, the area was proclaimed a protectorate. In 1904 responsibility for its administration was transferred from the Foreign Office to the Colonial Office. In 1907 the protectorate (known as the British Central Africa Protectorate after 1893) was named Nyasaland. Henceforth, for more than 50 years, its problems were mainly economic. With a crowded and growing African population and no exploitable mineral resources, Nyasaland remained poor and its chief export was manpower. In the 1930s it was realized that it would be difficult for the country to solve its economic problems in isolation and after World War II the idea of closer association with Southern Rhodesia was pursued.

In 1953 the protectorate of Nyasaland was included in a federation with two other British territories, Northern Rhodesia, also a protectorate, and Southern Rhodesia, a self-governing colony. The federal capital was located at Salisbury in Southern Rhodesia and the federal prime minister was Sir Godfrey Huggins. There were some disturbances in Nyasaland the same year, instigated by African opponents of federation. Political advancement continued and in 1955 the Legislative Council was reconstituted to include five Africans. In 1959 large-scale disorders broke out, a state of emergency was declared, Hastings Banda and other members of the Nyasaland African Congress were arrested, and a number of Africans were killed in clashes with security forces. In 1960 the report of the Monckton Commission indicated the strength of African opposition to the idea of federation. When, in 1961, elections were held under a new constitution, Banda's Malawi Congress Party gained control of the Legislative Council. In February 1963 Nyasaland achieved internal self-government and Banda took office as prime minister. The federation was dissolved at the end of 1963 and in July 1964 Nyasaland achieved independence under the name of Malawi. (K. G. B.; X.)

NYAYA, one of the six systems of thought into which ancient Indian philosophy divided itself in the centuries following the Epic period (*see* INDIAN PHILOSOPHY). For its outstanding achievement *see* LOGIC, HISTORY OF.

NYCTEUS, in Greek legend, father of Antiope, whose sons Zethus and Amphion were to build the walls of Thebes; brother of Orion, the giant hunter. Nycteus' father, Hyrieus, the founder and eponymous hero of the Boeotian town of Hyria, had been long childless until Zeus, Poseidon and Hermes on a visit remedied this. Nycteus and his brother Lycus, in what may be a later tradition, intrude into the Cadmeian dynasty of Thebes by acting in turn as guardians of the infant Laius, who was to be the father of Oedipus. (H. W. PA.)

NYE, EDGAR WILSON (BILL NYE) (1850–1896), U.S. journalist, humorist and lecturer, was born in Shirley, Me., on Aug. 25, 1850. In 1852 the family moved to Wisconsin, where Nye attended River Falls academy, taught school and read law. Settling in Laramie, Wyo., in 1876, he served as postmaster and justice of the peace, and contributed to the *Denver Tribune* and *Cheyenne Sun*. His humorous squibs and tales in the *Laramie Boomerang*, which he helped found in 1881, were widely read and reprinted. Collected, they form the substance of several published volumes. Later Nye returned to Wisconsin, and for several years wrote for the *New York World*. In 1886 he lectured with James Whitcomb Riley, the combination of Nye's wit and Riley's sentiment proving extremely popular. He continued writing, but

he suffered from poor health, and spent his last days in Arden, N.C., where he died on Feb. 22, 1896.

Nye is associated with Charles F. Browne ("Artemus Ward" [*q.v.*]), David R. Locke ("Petroleum V. Nasby" [*q.v.*]), Henry W. Shaw ("Josh Billings" [*q.v.*]) and other professional humorists who flourished after the Civil War. But he avoids their political satire and their tricks of faulty spelling, grammar and diction. Writing in his own person, rather than in the guise of a foolish character, Nye reveals his own kindly but droll nature. Possibly for these reasons he has worn better than some of his humorous contemporaries.

See F. W. Nye, *Bill Nye: His Own Life Story* (1926). (L. T. D.)

NYERERE, JULIUS KAMBERAGE (1922–), president of Tanzania and an important figure in the Organization of African Unity, was born in March 1922, the son of a chief, at Butiama, Musoma district, Tanganyika. First educated locally, he went to Makerere College, Uganda, in 1943, in which year also he became a convert to Roman Catholicism. At Makerere College he joined a branch of the Tanganyika African Association (the TAA), a moribund organization of African civil servants. On leaving Makerere in 1945, Nyerere went to teach at St. Mary's Roman Catholic school at Tabora. In 1949 he went to Edinburgh University, where he took an arts degree, returning afterward to teach in Tanganyika. In 1953 he was elected president of the TAA, which he soon converted into a lively political organization with the title Tanganyika African National Union. In 1954 and 1957 he served briefly as a member of the Legislative Council and became an elected member in 1958. In 1957 he addressed the UN Trusteeship Council in support of ultimate independence for Tanganyika with an African majority government. In September 1960, when Tanganyika gained responsible self-government, Nyerere became chief minister, and he was the first prime minister of independent Tanganyika from December 1961. When Tanganyika became a republic a year later he was elected president, and in 1964 he became president of the United Republic of Tanzania (Tanganyika and Zanzibar). His policy was consistently one of nonracialism inside Tanganyika and of nonalignment outside. (K. I.)

NYIKA, the Northeast Coastal Bantu tribes, including the Digo, who live along the Kenya and Tanganyika coast south from Mombasa to Pangani; the Giryama, who live north of Mombasa; and the Duruma, Jibana, Rabai, Ribe, Chonyi, Kauma and Kambe, who live in the arid bush steppe (*nyika* in Swahili) west of the Digo and Giryama. In the 1960s they were estimated to number 300,000. Most Nyika are of medium height, muscular, broad-headed and dark brown in complexion. Some, because of intermarriage with Arabs and Cushites, are slender, lighter brown and have narrow faces. Modern Nyika wear loincloths and pleated kilts or Swahili and western garments. They build rectangular mud, wattle and thatch houses or loaf-shaped grass huts and live in dispersed homesteads or compact villages. Before European rule ended tribal war they lived in fortified villages known as *kaya*.

Many Nyika are Muslims, some are Christians, and perhaps a quarter retain the traditional native faith. There is widespread belief in Islamic, pagan and ancestral spirits thought to require ritual placation. Nyika are governed by officials appointed by the Kenya and Tanganyika governments. Traditionally they were ruled by elders deriving authority from age grade (*see* AGE SET) and rank in secret societies. Digo social organization is bilateral, Duruma is double unilineal and the others are patrilineal. Nyika are cultivators and keepers of livestock. Some work in urban centres and on plantations. Many are traders, hunters, and fishermen. *See* AFRICA: *Ethnography* (*Anthropology*): *East Africa.*

(L. P. GE.)

NYÍREGYHÁZA, a town of northeast Hungary in Szabolcs-Szatmár *megye* (county), 169 mi. (272 km.) E.N.E. of Budapest by rail, is the main urban settlement of the Nyírség region. Pop. (1960) 56,834 (mun.). Nyírség was for centuries a spectacular wilderness of dune and fen, but it has been gradually reclaimed for farming, and its sandy soils are well cultivated. The countryside is noted for its *tanya* settlements (small isolated farms or groups of farmsteads). There are 73 identifiable separate hamlets round the town, originating from family colonies, each of which once had its own small school. The town is now an important road and rail intersection point. Since World War II light industry (hosiery) has developed, but Nyíregyháza remains chiefly a market for farm products, especially tobacco, potatoes and vegetables.

The history of Nyíregyháza as a town really begins with the determined effort of Count Ferenc Károlyi in the mid-18th century to colonize the region. The settlement of Slovak immigrants was conspicuous; they were known as *Tirpaken* ("without possessions") and their descendants, although more prosperous, still often bear the nickname. (H. G. S.)

NYLON: *see* FIBRE.

NYMPH, in Greek mythology the generic name of a large class of inferior female divinities. The word nymph is of uncertain etymology and means simply a marriageable woman; this is appropriate, for the nymphs are mostly associated with fertile, growing things, such as trees, or with water. Superior deities especially associated with them are Artemis, Apollo, Dionysus, Pan and Hermes. The nymphs were not immortal but were extremely long-lived; they were on the whole kindly disposed toward men. They were distinguished according to the sphere of nature with which they were connected. The Oceanids, for example, were sea nymphs, daughters of Oceanus and Tethys; the Nereids (*q.v.*), daughters of Nereus and Doris, inhabited both salt and fresh water; the Naiads (*q.v.*) presided over springs, rivers and lakes. The Oreads (*oros*, "mountain") were nymphs of mountains and grottoes; one of the most famous of these was Echo (*q.v.*), who either was vainly loved by Pan or herself vainly loved the fair youth Narcissus. The Napaeae (*nape*, "dell") and the Alseids (*alsos*, "grove") were nymphs of glens and groves; the Dryads (*q.v.*) or Hamadryads presided over forests and trees.

Italy had native divinities of springs and streams (Juturna, Egeria [*qq.v.*], Carmentis, Fons) and water-goddesses called Lymphae (originally Lumpae) with whom the Greek nymphs tended to become identified.

NYMPHAEUM, a monument consecrated to the nymphs (*q.v.*), especially those of springs. These monuments were originally natural grottoes, which were traditionally considered the habitations of the nymphs. They were arranged to furnish a supply of water. Subsequently, artificial grottoes took the place of natural. The nymphaea of the Roman period were borrowed from the Hellenistic east (*e.g.*, the Great Nymphaeum of Ephesus). The majority were rotundas, adorned with statues and paintings. They served the threefold purpose of sanctuaries, reservoirs and assembly rooms. A special feature was their use for the celebration of marriages. Such nymphaea existed at Corinth, Antioch and Constantinople; the remains of about 20 have been found at Rome and of many in Asia Minor, Syria and Africa. The term nymphaeum was also applied to the fountain in the atrium of the Christian basilica. *See* FOUNTAIN.

NYORO (Banyoro, Wanyoro, Kitara, Bakitara), a Bantu-speaking people of Uganda (*q.v.*) inhabiting the area east of Lake Albert between the Victoria Nile and the Kafu (*see* BANTU [INTERLACUSTRINE]). Before the growth of Ganda power in the 19th century, the Nyoro kingdom was the political focus of the region, controlling the now-independent Toro and the present Mubende district of the Ganda kingdom. The Haya, Nkole and northern Soga states also have traditional links with the Nyoro kingship, as also have some of the Nilotic Lango and Acholi. Including those living in areas presently controlled by the Ganda, but not including Toro, the Nyoro numbered about 200,000 in the 1960s.

Nyoro society was traditionally divided into two main categories which, however, are no longer distinct: the Iru (Bairu),

settled agriculturalists who grew millet and sweet potatoes; and the Huma (Bahuma), who were mainly transhumant cattle-keepers. A third category, the Bito (Babito), were of Nilotic origin and provided the ruler of the state, the *Mukama*. Chiefs of districts were appointed by the *Mukama* from all sections of the population. Nyoro religion was centred upon communication (through mediums) with the spirits of ancestors, natural phenomena and a pantheon of god-kings (*bacwezi*) who were believed to have formed a dynasty that ruled prior to the Bito.

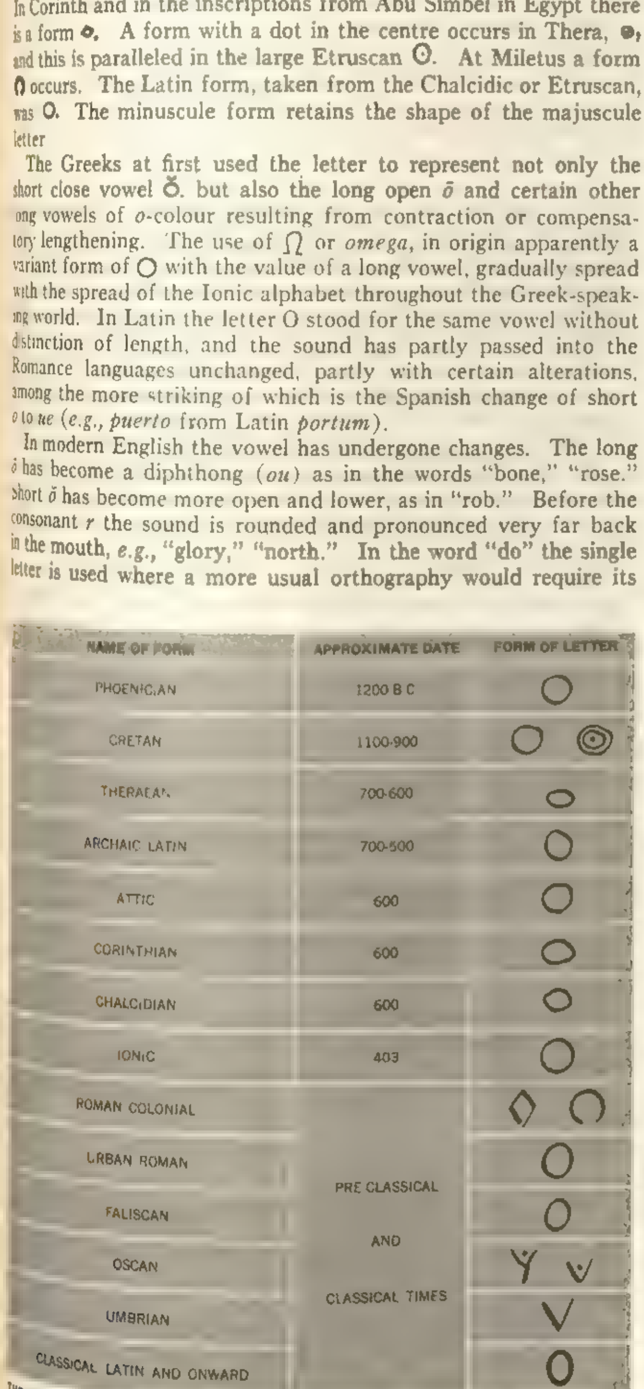
NYX, "Night," in Hesiod, daughter of Chaos and mother of numerous primordial powers including Sleep and Death. Orphic myth makes her rule the gods after her father, Phanes, and dominate her successors (Uranus, her son by Phanes; Cronus and Zeus) by her oracular gifts. Throughout antiquity she caught the imagination of poets and artists but was seldom worshiped.

(D. E. W. W.)

O THIS letter, the fourth vowel of the modern alphabet, corresponds to the Semitic *ayin*, which represented a breathing and not a vowel. The Semitic form may derive from an earlier sign representing an eye. The Greeks in adapting the Semitic alphabet to their own use used this letter (*omicron*) to express the vowel O, as the letters *aleph, he, cheth* and *yodh* were used to express vowels. Vowels were not expressed alphabetically in Semitic. The form of the letter on the Moabite stone was small O, and this small form appears in early Greek inscriptions from Thera and Corinth. In Corinth and in the inscriptions from Abu Simbel in Egypt there is a form ◇. A form with a dot in the centre occurs in Thera, ⊙, and this is paralleled in the large Etruscan ʘ. At Miletus a form Ο occurs. The Latin form, taken from the Chalcidic or Etruscan, was O. The minuscule form retains the shape of the majuscule letter

The Greeks at first used the letter to represent not only the short close vowel ŏ. but also the long open ō and certain other long vowels of *o*-colour resulting from contraction or compensatory lengthening. The use of Ω or *omega*, in origin apparently a variant form of O with the value of a long vowel, gradually spread with the spread of the Ionic alphabet throughout the Greek-speaking world. In Latin the letter O stood for the same vowel without distinction of length, and the sound has partly passed into the Romance languages unchanged, partly with certain alterations, among the more striking of which is the Spanish change of short *o* to *ue* (*e.g., puerto* from Latin *portum*).

In modern English the vowel has undergone changes. The long *ō* has become a diphthong (*ou*) as in the words "bone," "rose." Short *ŏ* has become more open and lower, as in "rob." Before the consonant *r* the sound is rounded and pronounced very far back in the mouth, *e.g.,* "glory," "north." In the word "do" the single letter is used where a more usual orthography would require its doubling. Again in the word "son" one would expect the vowel *u*. In words such as "word," "work," "world" the sound has been affected by the preceding bilabial. The short sound is the descendant of Middle English short *ŏ* in which both the close and open short *ŏ*, which were distinguished in Old English, met. The long *ō*, now a diphthong, descends from Middle English long *ō*, an open sound, which was derived from Old English long *ā*. In Middle English this was a rounded back vowel akin to the modern vowel in "shore," "north." Old English close long *ō* became in Middle English *oo* (*ū*). *See* also ALPHABET. (B. F. C. A.; J. W. P.)



THE DEVELOPMENT OF THE LETTER "O" FROM THE PHOENICIAN THROUGH CLASSICAL LATIN TO THE PRESENT FORM

OAK is the common name for more than 300 species of trees and a few shrubs belonging to the genus *Quercus* of the beech family (Fagaceae).

True Oaks.—Oaks are widely distributed throughout the temperate regions of the northern hemisphere and are quite abundant at high elevations in many parts of the tropics. A few are found below the equator, in the new world as far south as Colombia and in the old to the Indian archipelago. Their greatest concentration occurs in the highlands of Mexico, especially in the Sierra Madre range where they are the principal components of vast mixed hardwood forests. Several of the oaks indigenous to the eastern United States are productive of some of the world's finest cabinet and structural timbers. The forests of Japan, India, the U.S.S.R., Czechoslovakia and Poland also include valuable timber-producing species.

As a group the oaks are characterized by alternately disposed, simple, deciduous or evergreen leaves with lobed, toothed or entire margins and a featherlike arrangement of their principal veins. Their small inconspicuous unisexual flowers are borne in separate inflorescences on the same plant (monoecious). The male or staminate flowers are borne in many-flowered, sulfurous-yellow, pendent catkins that appear with or after the leaves, each being comprised of a 4- to 7-lobed calyx and 4 to 12 (mostly 6) stamens. The female or pistillate flowers; by contrast, appear in few-flowered spikes or are solitary. Each flower consists of a 6-lobed calyx and 3- to 5-celled pistil, the whole partially enveloped by many involucral bracts. The fruit of the oak is the distinctive acorn, a nut that is partially (rarely wholly) encased in a "cup" composed of the greatly enlarged involucral bracts that attended the pistillate flower. The bark pattern of oak trees varies greatly not only among species but often within a species of different age classes. The bole of several species features transverse and longitudinal fissures resulting in a blocklike configuration reminiscent of alligator leather. Barks of other trees are often smooth, superficially scaly, plated or irregularly ridged between deep longitudinal and often anastomosing furrows.

On the basis of certain common botanical features the genus *Quercus* is readily divided into three very distinctive subgeneric groups known as the *Cyclobalanus, Leucobalanus* and *Erythrobalanus* oaks. *Cyclobalanus* oaks feature fruits in which the involucral bracts of the acorn cups are fused together into several concentric rings. In the other two groups the bracts are spirally arranged. *Leucobalanus* oaks, commonly known as the white oaks, feature leaves with smooth or occasionally glandular margins but are never bristle tipped. Their acorns, which mature at the end of a single growing season, are usually sweet meated and germinate within a few days following their fall. *Erythrobalanus* oaks, the red or black oaks of commerce, in contrast, are characterized by leaves with bristle-tipped lobes and apices, and astringent fruits that not only mature at the end of two growing seasons but also winter over and germinate the following spring. The term "live" oak is applied to any of the oaks that feature persistent, evergreen foliage.

Of the more than 85 species of *Quercus* indigenous to the United States, more than 50 attain the stature of large trees, and fully half of these are of primary importance in the timber industry.

Many of them attain heights in excess of 100 ft., and diameters of from 4 to 7 ft. are not at all uncommon. While oaks are found in every forested region in the United States, the chief centres of oak lumber production lie in the southeast.

Among the most valuable of the eastern leucobalanus oaks are the white oak (*Q. alba*), a tree 80 to 100 ft. tall with a trunk 3 to 5 ft. in diameter, productive of some of the world's finest white oak lumber; the massive bur oak (*Q. macrocarpa*), often 150 to 170 ft. high and 4 to 7 ft. in diameter, easily recognized by its corky twigs, obovate leaves with deep central sinuses and large fruits, the fringed cups of which nearly enclose the nut; the post oak (*Q. stellata*) with its leaves in the form of a cross; the chestnut oak (*Q. prinus*) and swamp chestnut oak (*Q. michauxii*), two species with chestnutlike leaves, the former an upland form, the latter largely restricted to permanently wet sites on the coastal plains; and the overcup oak (*Q. lyrata*), another denizen of southern coastal swamps, readily recognized by its irregularly lobed leaves and large nuts completely enclosed in thin scaly cups. The eastern red oaks of primary importance to the lumber industry include the northern red oak (*Q. rubra*), the fastest growing of the eastern oaks which at maturity often attain a height of 150 ft.; the black oak (*Q. velutina*) another equally large tree, whose bark is the source of a yellow dye principle, quercitron (*see* QUERCITRON BARK); the Shumard oak (*Q. shumardii*); the scarlet oak (*Q. coccinea*); and the willow oak (*Q. phellos*) a large tree of the southern coastal plains with willowlike leaves, commonly used as a street and shade tree throughout many of the southern states. The live oak (*Q. virginiana*), the only evergreen oak in eastern United States, was once highly prized by both British and American shipbuilders.

J. HORACE MCFARLAND CO.

LEAVES AND ACORNS OF THE WHITE OAK (QUERCUS ALBA)

The oaks of the Rocky mountain region are mostly small trees that at high elevations are little more than shrubs. The Gambel oak (*Q. gambelii*), rarely 45 ft. tall, is the largest oak in Colorado, and the somewhat larger Arizona white oak (*Q. arizonica*), is the principal oak of Arizona and New Mexico.

A number of deciduous and evergreen oaks are indigenous to the Pacific slope. The most important of these is the Oregon white oak (*Q. garryana*), found from British Columbia to San Francisco bay, commonly used locally in the production of furniture and flooring. Two other deciduous species, the California white oak (*Q. lobata*), a massive tree with a crown spread of 150 or more feet, and California black oak (*Q. kelloggii*), are trees of secondary importance. Among the evergreen species are the interior live oak (*Q. wislizenii*) with hollylike leaves; canyon live oak (*Q. chrysolepis*) with small, thick, unlobed leaves and woolly twigs, the California live oak (*Q. agrifolia*) and the small shrublike California scrub oak (*Q. dumosa*).

The timber of both the American red and white oaks is put to many diverse uses. The better grades of lumber are used for flooring, furniture, paneling and millwork. The white oaks are admirably suited for staves and headings for tight cooperage. Large quantities are also consumed in the production of crossties, structural timbers and mine props, stulls and sills.

Among other important oaks of the world particular mention should be made of the cork oak (*Q. suber*), a small- to medium-sized tree of the Mediterranean basin, the bark of which is the principal source of the world's supply of commercial cork (*q.v.*).

The brown oak (*Q. robur*), the only oak indigenous to England, is a cosmopolitan tree of wide distribution through most of the milder parts of Europe and the Caucasus mountains in Asia. At least 40 varieties are known in cultivation. Long noted for its heavy, fine-grained, rich brown heartwood, it was once used in the construction of British merchant shipping. At one time it was also a favourite of wood carvers, and the shrine of Edward the Confessor in the abbey at Westminster was fabricated of this handsome wood. This species, also known as English oak, attains great longevity, and many of the largest trees still standing in the British Isles are believed to date from Saxon times. One venerable old forest giant, the celebrated Newland oak in Gloucestershire, known for centuries as "the great oak," was 47.5 ft. in diameter 5 ft. from the ground at the time of its destruction.

The Turkey oak (*Q. cerris*) abounds over the Taurus ranges along the Turkish peninsula and in many other parts of southern Europe. It is also a common ornamental plant in England and in several of the older cities of eastern United States.

The evergreen holly oak (*Q. ilex*) is indigenous to southern Europe and northern Africa. In its native lands it attains great age. Pliny attributed to several trees growing in Rome a greater antiquity than the city itself.

While the oaks are principally known for the many fine timbers they produce, several of them are also important sources of other valuable forest products. The kermes oak (*Q. coccifera*), a small bushy tree of the Mediterranean basin, is heavily preyed upon by kermes, small insects whose body juices are bright red and which are used as a source of dye. Tannin (*q.v.*), a chemical complex used in converting raw hides to leather, is obtained in commercial quantities from the barks of several oaks. Valonia tannin is traceable to the acorn cups of *Q. aegilops*, a small tree indigenous to Greece and the coasts of the Levant, while Aleppo tannin is derived from insect galls commonly found on the twigs of the Aleppo oak (*Q. infectoria*), a Turkish tree. The acorns of several oaks are a common article of diet of small game, and because of their high nutritive value have been used to fatten swine.

Leaf-eating organisms (tent caterpillars; larvae of gypsy, Luna, browntail, Cecropia and buck moths; striped oak, American silk and canker worms) commonly denude several species of oak but seldom bring about their death. Other insects cause unsightly twig and leaf galls. Oak wilt fungus causes severe loss in several areas, threatening extinction of some species.

Other Trees Bearing the Name of Oak.—Several other unrelated groups of trees, the timbers of which also display large prominent wood rays that on the quarter section of boards give rise to a spangled figure, are likewise known in the lumber trade as oaks. Notable among these are the Australian silky and satin oaks, a group of highly prized ornamental woods traceable to the genera *Cardwellia, Grevillea, Embothrium* and *Orites* of the Proteaceae. The tulip oaks, another group of Australian trees, belong to the genus *Tarrietia* of the cocoa family (Sterculiaceae; *q.v.*). The she (or shee) oaks, including beef oak and flame oak are members of the genus *Casuarina* of the Casuariniaceae, a monotypic family widely distributed through the southern hemisphere but most abundant in Australia. African oak timber is the product of two unrelated species from the Ivory Coast, *Oldfieldia africana* and *Lophira alata*. Wood of the former has been used in marine construction by the British navy but is virtually unknown in the United States.

Tanoaks belong to the genus *Lithocarpus*, also a member of the Fagaceae and may be distinguished from the true oaks on the basis of their unisexual flowers, which appear in bisexual catkins.

See also TREE; FAGACEAE; WOOD; and references under "Oak" in the Index.

OAKHAM, a market town and urban district in the Rutland and Stamford parliamentary division, and the county town of Rutland, 17 mi. E. of Leicester. Pop. (1961) 4,571. It is an ancient market town in the fertile Vale of Catmose and the headquarters of the Cottesmore hunt. By the market place with its old octagonal Butter cross stands the Norman castle, originally a fortified manor house, which has a banquet hall hung with a collection of the horseshoes presented by custom since the time

of Elizabeth I to the lord of the manor by royalties and peers passing through the lordship for the first time. All Saints parish church, dating from *c.* 1190, is mainly Perpendicular. The grammar school was founded in 1584. Light industries include the manufacture of hosiery and shoes.

OAKLAND, a city of California, U.S., is the county seat of Alameda county and part of a metropolitan area surrounding San Francisco bay in central California. The city land area covers 53 sq.mi. in the centre of a continuously built-up plain between the east shore of the bay and parallel ranges of hills. The east bay also includes the cities of Richmond and Berkeley on the north, Alameda across a narrow estuary to the west and San Leandro and Hayward (*qq.v.*) to the south, together with the smaller communities of Albany, El Cerrito, Emeryville and Piedmont. Residential areas rise into the hills, and extend beyond them where the Broadway tunnel opens a way into the valleys of Contra Costa county.

The population in 1950 was 384,575 and in 1960, 367,548 by federal census. The population of the San Francisco-Oakland standard metropolitan statistical area, which includes Alameda, Contra Costa, Marin, San Francisco, San Mateo and Solano counties, was 2,783,359 in 1960. In 1963, Solano county (1960 pop., 134,597) was deleted. (For comparative city population figures *see* table in CALIFORNIA: *Population.*)

History.—The east bay was settled by the Spanish in 1820, when Luis Maria Peralta received a royal grant of about 48,000 ac. and established the Rancho San Antonio. In 1849 Moses Chase leased land for farming and laid out a town named Clinton in the area of east Oakland. In 1851 Horace W. Carpentier gained control of a large section of waterfront and started a ferry to San Francisco. The following year he secured a town site and named it Oakland after the live oaks on the grassy plain. In 1854 Carpentier and his associates extended the area and reincorporated it as a city. In spite of bitter competition, Carpentier and the railroads which later took over his interests maintained control of access to San Francisco through the old waterfront claims. By 1885 the Southern Pacific railroad had established its western terminus on the Oakland mole and was operating numerous ferries. In 1903 the Key system, formed out of a small railroad and local electric lines, began another system of ferries. The 1906 earthquake and fire in San Francisco caused a shift of population to Oakland, and regular commuter traffic across the bay increased rapidly.

Under Frank K. Mott, mayor from 1906 to 1915, a new city hall and auditorium were constructed, large areas to the south annexed and a new charter adopted. Most important of all, the city secured court decisions breaking the railroad monopoly on the waterfront and gained control of the tidelands in 1911.

Thereafter, the commercial and industrial growth of the east bay was rapid, and it ceased to be primarily a "bedroom" for San Francisco. World War II brought tremendous military and naval activity, and the construction of extensive shipyards. This expansion continued in the postwar years, until the whole area from the refineries of Richmond to the orchards of Hayward became a continuous urban complex.

Administration.—Oakland is governed under a charter adopted in 1911 and amended in 1931 and 1951 to provide for a council elected by a city-wide vote, a city manager appointed by the council and a popularly elected mayor. The council appoints commissioners for the port, the parks, recreation, city planning and civil service.

Since 1923 water has been supplied through the East Bay Municipal Utility district, which received rights to the water of the Mokelumne river in the Sierra Nevada. Construction of the Pardee dam and aqueducts across the San Joaquin valley provided enough water to expand the district to include 225 sq.mi. of the east bay. In 1944 Oakland and six neighbouring municipalities placed their common problems of sewage treatment and disposal in the hands of the district.

The state of California bridge authority operates all toll bridges crossing the bay. It built the tremendous double-deck bay bridge from Oakland to San Francisco, which is 8¼ mi. long, including the approaches. The bridge was an immediate success when it was opened in 1936, but was already inadequate ten years later. Controversies regarding the location of a second bridge to San Francisco were not resolved, but a new bridge from Richmond across the northern arm of the bay was completed in 1956. In 1957 a San Francisco Bay Area Rapid Transit district was created by the state to plan an integrated system of public transportation for the region. The same procedure of creating special districts in the bay area has been used to deal with the problems of water pollution and smog control.

Commerce and Industry.—The port of Oakland covers 19 mi. of waterfront in the outer, middle and inner harbours. Including the Alameda side of the inner harbour, it handles 4,000,000 tons of cargo annually. There are large terminals and warehouses, shipbuilding and repair yards, dry docks, small-boat harbours, various industries, an international airport and Jack London square, a restaurant area developed by the port commissioners. The Oakland army base, the Oakland naval supply centre, and the naval air station in Alameda across the estuary are tremendous installations, covering over 3,000 ac. of filled land. Large areas in the north harbour and around San Leandro bay are held by the port for further development, as well as 8,000 ac. of submerged land annexed in 1955 to provide for the expanding airport.

The principal industries of Oakland and the east bay include food processing and milling, oil refining, manufacture of automobiles, calculating machines, electrical equipment, containers of all kinds, steel fabrication, chemicals and drugs. Oakland is headquarters for Kaiser Industries Corp. and the related Kaiser enterprises, which have built a large and strikingly beautiful office building overlooking Lake Merritt.

Education.—Public education is in the hands of an elected school board, which maintains a junior college and 5 senior high schools as well as more than 75 junior high schools and elementary schools. Mills college, founded in 1852, the oldest college for women in the far west, occupies a 136 ac. campus in east Oakland. The College of the Holy Names (for women) and the California College of Arts and Crafts are inside the city, and St. Mary's college (for men) is in the Moraga valley to the east. The University of California is in Berkeley, about a mile from the city line.

Oakland maintains a public library system, an art gallery, a public museum, the Woodminster outdoor theatre and the Chabot observatory.

Parks.—The park system includes Lake Merritt, a large salt water inlet from the estuary near the heart of the city. In the park around its shores are the children's fairyland and the waterfowl sanctuary, established in 1867, the first public wild fowl refuge in the United States.

Oakland includes the Knowland state park and arboretum, and is adjacent to large areas in the Contra Costa hills maintained by a regional park district. (F. H. HK.)

OAKLEY, ANNIE (in full PHOEBE ANNE OAKLEY MOZEE) (1860–1926), U.S. markswoman best known as "Little Missy" of Buffalo Bill's Wild West show, was born on a farm in Darke county, O., Aug. 13, 1860. As a youngster she won local acclaim for marksmanship and after winning a shooting match at Cincinnati with ranking marksman Frank E. Butler became a nationally known figure. Later Butler and Annie were married and together they successfully toured the vaudeville circuits and circuses until 1885 when the "Butler and Oakley" team joined the Buffalo Bill (William F. Cody) show and remained with it for 17 years. So startling were "Little Missy's" performances and so enthusiastic her audience response that she was given main billing as "Miss Annie Oakley, the Peerless Lady Wing-Shot," while her husband served as manager and attendant. Annie's was always the opening act in the Wild West show, and the performances were incredible. Her most spectacular feats were, at 30 paces, to hit the thin edge of a playing card, a dime tossed in the air and the end of a cigarette held in Butler's lips. Once while performing at Berlin she obliged Crown Prince Wilhelm (later Kaiser Wilhelm II) by performing the cigarette act while the prince held the cigarette. Everywhere that the Buffalo Bill show traveled—at home and abroad—the

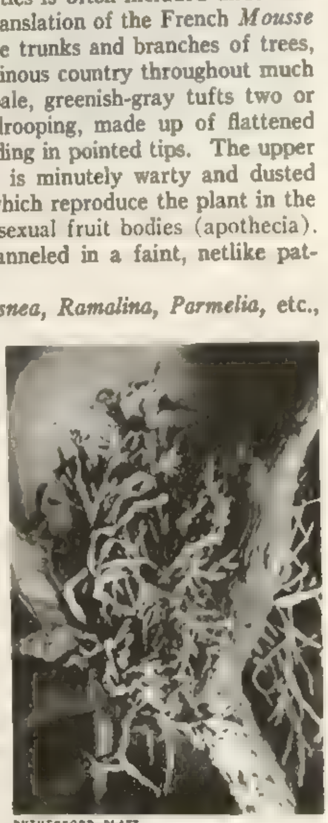
acclaim for Annie Oakley was spontaneous and great. In 1901 she was severely injured in a train wreck but recovered and continued her performances. She died at Greenville, O., on Nov. 3, 1926, and was buried at Brock, near her Ohio birthplace. Her husband died three weeks later.

One of many reminders of this remarkable woman is the use of her name to denote a complimentary ticket. The hole customarily punched in such a free pass recalls the bullet holes that she shot in small cards during her theatrical performances. A free ticket thus came to be known as an "Annie Oakley."

See Walter Havighurst, ***Annie Oakley of the Wild West*** (1954).
(O. O. W.)

OAK MOSS (*Evernia prunastri*), a lichen containing an oleoresin valued in perfumery both for its own fragrance of a heavy, oriental type and as a fixative base. Another species (*E. furfuracea*) having similar properties is often included under the same common name, which is a translation of the French *Mousse de chêne.* Oak moss grows on the trunks and branches of trees, also on poles and rails, in mountainous country throughout much of the northern hemisphere, in pale, greenish-gray tufts two or three inches long, extending or drooping, made up of flattened strands which fork repeatedly, ending in pointed tips. The upper or outer surface of these strands is minutely warty and dusted with pale-gray soredia, particles which reproduce the plant in the absence of the rare, disk-shaped, sexual fruit bodies (apothecia). The under surface is whitish, channeled in a faint, netlike pattern.

Other lichens of the genera *Usnea, Ramalina, Parmelia,* etc., which grow intermingled with the *Evernia,* frequently gathered with it in the commercial product, have little fragrance, but may contribute to the value of the oleoresin as a base. Chief sources of oak moss from about 1900, when the perfume first came into general use, until 1940, were Yugoslavia and France, large quantities being shipped for distillation in northern Europe. After the disruption of trade by World War II, investigation showed the lichens to exist in Canada and northern United States, and they have been distilled in America to a limited extent.



RUTHERFORD PLATT

OAK MOSS (EVERNIA PRUNASTRI) GROWING ON THE BRANCH OF AN INCENSE CEDAR TREE

Oak moss was used in perfumery as early as the 16th century and later forgotten. Baskets filled with it have been found in the ancient royal tombs of Egypt, but whether intended for perfume or, as some suggest, for making bread, is not known. It contains a starchy edible substance.

OAK PARK, a village of Illinois, U.S., in Cook county, west of and adjacent to Chicago. Oak Park was first settled in 1833 and served as a stopping place for farmers taking their produce into Chicago. In 1871 after the Chicago fire the population grew rapidly, and in 1901 the village was incorporated. Primarily a residential community, Oak Park has an extensive retail trade, little light industry and no heavy industry. Oak Park is unusual in possessing 24 homes designed by Frank Lloyd Wright. It has a number of public and parochial schools and a Catholic military academy. In 1953 Oak Park adopted a village manager-council form of government. For comparative population figures *see* table in ILLINOIS: *Population.* (J. ZA.)

OAK RIDGE, a city of Tennessee, U.S., is about 20 mi. N.W. of Knoxville, at the eastern end of a remote 58,800-ac. tract selected in 1942 as headquarters site for the U.S. wartime atomic energy program, the Manhattan project. Originally known as the Clinton Engineer works, Oak Ridge was picked for the vital government installation because it was isolated, yet accessible to power, water, transportation and manpower. Army engineers began work in early 1943 on the community to house project personnel. The town, built in 2½ years behind security fences, reached a peak population of 75,000 in 1945. Maximum wartime employment was 82,000. After World War II, Oak Ridge's population declined, so that in 1960 the population was 27,169. For comparative population figures *see* table in TENNESSEE: *Population.*

In the latter 1950s the internationally known community, by then headquarters for a major Atomic Energy commission field office, was still centred about a single industry, atomic energy. The government investment at Oak Ridge totaled $1,500,000,000 in two huge uranium processing plants and Oak Ridge National laboratory.

Oak Ridge bears slight resemblance to the temporary wartime boom town. In 1949 fences were removed from the community area. In 1953, roads through the plant areas were opened, and for the first time land was leased for private construction. New churches and schools were built as were many homes.

In 1955 congress provided for the sale of property in Oak Ridge, and in Sept. 1956, the first government-owned house was sold. In less than a year, Oak Ridge became the city with the largest percentage of individual home ownership in the U.S. The resulting renovation and remodeling effected a major face-lifting in the community.

Oak Ridge, which from its inception depended upon the federal government for services normally rendered by municipal government, was incorporated in 1959. (J. A. Hs.)

OANNES, in Babylonian mythology an amphibious being who taught mankind wisdom. He was called thus by the Babylonian priest Berossus, writing in Greek in the 3rd century B.C. (Oannes' name is sometimes also found in the forms Iannes, Euhanes. Fragments of Berossus' writings are preserved by the Jewish historian Flavius Josephus (1st century A.D.) and by the Christian historian Eusebius of Caesarea (3rd–4th century A.D.), the latter transmitting the Oannes legend from earlier Greek sources. Berossus describes Oannes as having the form of a fish, but with under his fish's head, the head of a man and, under his fish's tail the feet of a man. He rose in the daytime from the waters of the Persian gulf and, upon the seashore, instructed mankind in writing, the arts and the sciences. Likewise upon the seashore was the city Eridu, sacred to Ea (*q.v.*), god of the freshwater deep and of wisdom and symbolized as a "goat fish." But the possibility that Oannes and Ea were identical is remote. Oannes is more likely to have been Ea's emissary, sent by him to educate mankind. (T. FH.)

OARFISH, any oceanic fish of the family Regalecidae (a group sometimes included in the closely related dealfish family, Trachypteridae), characterized by a long, compressed silvery body; short head; large eyes; and long, coral red dorsal fin that forms a crest on the top of the head. Oarfishes and their relatives are fragile, usually deepwater species that are rarely seen alive dead or dying specimens being beached occasionally. The long filamentous pelvic fins ending in oarlike expansions give the family its common name. Oarfishes, especially the widely distributed giant oarfish or king of the herrings (*Regalecus glesne*), may reach a length of about 30 ft.; such large individuals are undoubtedly the basis for some of the reports of undulating sea serpents. *See* also FISH; SEA SERPENT.

OASIS, a fertile tract occurring in a desert wherever a perennial supply of fresh water is available. Oases vary in size from a few acres around small springs to vast areas of naturally watered or irrigated land. The largest occur along rivers traversing deserts from headwaters in distant rainy regions; in Egypt, for example, most of the population is concentrated within the nearly 14,000 sq.mi. of the intensively cultivated, irrigated land along the Nile river.

Underground water sources account for large numbers of oases, where springs and wells, many of them artesian, are supplied from sandstone and limestone aquifers. (*See* also GROUND WATER.) The oases of Kharga and Dakhla, northwest of Aswan in the Libyan desert, are watered by an aquifer whose area of water ac-

cumulation lies more than 500 mi. to the south in the Sudan. Water from the deep Artesian basin underlying much of southwestern Queensland, Austr., is widely used for watering livestock but is too saline for crop irrigation.

Desert oases are almost invariably under cultivation. In the Sahara the date palm is characteristic and cotton, olives, figs, citrus, tomatoes, gourds, onions, mint, fennel and numerous other fruits, vegetables and herbs are cultivated. Barley, wheat, maize, millets, rice and other grains are economically important crops.

Heat oases occur in the cold arctic tundra (*q.v.*) where dark-coloured soil materials, which absorb solar radiation with greatest efficiency, are in a topographic position providing both protection from cold winds and exposure of the ground to the most direct angle with the sun. Greater variety of plant species and increased vegetative growth, flowering, intensity of flower coloration and seed maturation characterize these bright spots on the usually drab landscape. (M. E. B.)

OASTLER, RICHARD (1789–1861), English factory reformer, one of the instigators of the Ten Hours bill (1847), was born at Leeds on Dec. 20, 1789. In 1820 he became steward of Thomas Thornhill's estate at Fixby, near Huddersfield, Yorkshire. A Wesleyan family background and a Moravian schooling directed Oastler's attention to practical philanthropy as well as business. In 1830 John Wood, a Bradford worsted manufacturer, revealed to him some of the evils of child employment in the local factories. Oastler was shocked and wrote a vigorous letter, entitled "Yorkshire Slavery," to the *Leeds Mercury*, thereby starting an agitation which soon passed from philanthropy to politics.

During the next ten years Oastler was the most prominent of a band of Tory-Radicals who attacked the "factory system" and the poor law of 1834 and pleaded for a stable social order, based on the principle that "every man born in England has a natural right to live well." Although not a Chartist, he was just as prepared as the Chartists were to agitate when parliament seemed insensitive to operatives' pressure. For his efforts in the West Riding he began to be called the "Factory King," and at last, after many rebuffs, in 1847 a Ten Hours bill was passed by parliament, which appeared to secure the objectives he and his parliamentary colleagues, particularly Lord Shaftesbury, had demanded. A further act of 1850 was necessary to enforce the ten-hour law; by that time the factory reform movement was divided into hostile sections and Oastler was still dissatisfied with results.

His opposition to the poor law of 1834 had led to his dismissal from his stewardship, and being unable to pay an outstanding debt to Thornhill he was sent in 1840 to the Fleet prison where he spent more than three years. From prison he published the *Fleet Papers*, which summarize his philosophy. In 1844 his friends paid his debt, and after his release he was given a triumphal entry into Huddersfield. He died at Harrogate on Aug. 22, 1861.

BIBLIOGRAPHY.—W. R. Croft, *The History of the Factory Movement* (1888); B. L. Hutchins and A. Harrison, *History of Factory Legislation* (1926); C. Driver, *Tory Radical: the Life of Richard Oastler* (1946). (A. BRI.)

OATES, TITUS (1648–1705), renegade Anglican priest who, with Israel Tonge, invented the "popish plot" in 1678. He was born on Sept. 15, 1648, at Oakham, Rutland, the second son of Samuel Oates, an Anabaptist preacher, who was for some time chaplain in Col. Thomas Pride's regiment of foot. From his earliest years he seemed destined to a career of villainy. Expelled from Merchant Taylors' school, London, within a year of his admission, and sent down from both Caius and St. John's colleges, Cambridge, he yet secured admission to orders in the Church of England. He became successively vicar of Bobbing, Kent, in 1673, and curate to his father, who had conformed after the Restoration, at All Saints, Hastings, in 1674. While serving in the latter position, he made his first serious essay in the art of perjury by uniting with his father to bring scandalous and quite unfounded charges against a local schoolmaster whose place he coveted. He sought refuge from prosecution in the navy and in the summer of 1675 visited Tangier as chaplain to the "Adventure" man-of-war. From this post also he was dismissed on the return of the "Adventure" to England, yet early in 1677 he contrived to secure appointment to the position of chaplain to the Protestants in the household of the Roman Catholic duke of Norfolk.

There for the first time he came into intimate and extensive contact with Catholic circles, and was inspired by the association he had formed with Israel Tonge, a fanatical anti-Jesuit, to see what profit could be derived from them. He joined the Roman Catholic Church on March 3, 1677, and in the summer of the same year was sent to Spain to study for the priesthood at the English college at Valladolid; he later claimed to have received the degree of doctor of divinity from the University of Salamanca. His stay at Valladolid was short, however, for he was expelled within five months, only to secure admission instead to the English seminary at St. Omer, from which in turn he was expelled on June 23, 1678. Making his way back to London with a mass of miscellaneous information about the Catholics, he rejoined his ally Tonge, and on the basis of that information and Tonge's imagination the pair proceeded to draw up their account of a vast Jesuit conspiracy to assassinate Charles II, place James, duke of York, on the throne and recover England for the Roman Catholic Church. Tonge, with the utmost affectation of secrecy, took the first step toward making a disclosure of these designs to Charles II and the government on Aug. 12, 1678; and on Sept. 28, Oates, dissatisfied with the progress that had been made, deposited a written account of the plot with a prominent justice of the peace, Sir Edmund Berry Godfrey (*q.v.*), and swore to the truth of its contents.

The tale told by Oates was a clumsy fabrication, but unfortunately it contained just sufficient truth to enlist the support of the ignorant. It was welcomed by several of the contending factions at court, who imagined they could turn it to their own advantage; and it received immediate apparent confirmation with the discovery of Godfrey's corpse under circumstances never satisfactorily explained. A wave of terror swept over England which carried Oates to the summit of power. Hailed as the saviour of his country, rewarded with a pension, and provided with a guard, he found himself in a position to send to the scaffold almost anyone whom he cared to accuse, and did in actual fact bring about the death of about 35 more or less innocent persons. But as the frenzy died down, and too many imitators came forward with additions to his story, discrepancies became apparent which even his brazen assurance could scarcely brush aside, and his credit steadily declined. The queen's physician, Sir George Wakeman, against whom he had given evidence, was acquitted on July 18, 1679. In the following October, Oates was refused the degree of doctor of divinity by the University of Oxford. During the years 1681 and 1682 his pension was first reduced and then withdrawn altogether. In June 1684 damages to the enormous amount of £100,000 were awarded against him at the suit of the duke of York. Finally, in May 1685, he was convicted of perjury, subjected to a flogging from which he barely escaped alive and committed to prison for the remainder of his life.

After the revolution of 1688, Oates was released and once more granted a pension; but the refusal of the house of lords to reverse the sentence passed upon him precluded him from giving evidence in a court of law and so deprived him of his former means of livelihood. His efforts to train others to follow in his footsteps proved unsuccessful, and his marriage on Aug. 17, 1693, to Rebeccah Weld, daughter of a wealthy draper, followed shortly afterward by his admission to and expulsion from the Baptist Church, provoked little but mirth. By the time of Anne's accession in 1702 he had been practically forgotten, and his death in London on July 12 or 13, 1705, passed almost unnoticed.

BIBLIOGRAPHY.—Contemporary accounts of Titus Oates are largely the product of party passion, and cannot be relied upon. The only full-scale modern account is Jane Lane, *Titus Oates* (1949), which combines much accuracy in detail with a less satisfactory presentation of the general background against which Oates's career has to be considered. *See* also Sir John Pollock, *The Popish Plot*, new ed. (1944). (A. BG.)

OATH AND AFFIDAVIT. An oath is a statement or assertion made under penalty of divine retribution for intentional falsity; an affidavit is a formal written statement executed under oath. Both are employed throughout the Anglo-American world.

Oath.—Fealty to a sovereign, the obligations of public office and the ethical obligations of learned professions are all assumed by oath. The most frequent use, however, occurs when a witness in an authorized inquiry states his intention to give his pertinent knowledge and to tell only the truth in relating that knowledge. The precise formula varies, usually being prescribed by statute. A common formulation of the witness oath is: "I do solemnly swear that the testimony I am about to give will be the truth, the whole truth, and nothing but the truth. So help me God." In Anglo-American legal practice testimony will not be received unless the witness is subject to some sanction for falsity, the oath being the usual form. Civil-law nations use it more sparingly; they generally do not permit parties to the case to testify under oath and they make the oath voluntary with many others. In these countries the oath is often administered after rather than before the testimony is given.

Moral consequences may not vary with the manner of assuming the oath but temporal consequences do turn upon whether the administering officer was validly empowered and whether the proceeding was properly authorized. Judges, court officials and some other public officers have statutory power to administer oaths; normally consular officials and commissioned officers of the armed forces have the same power. One of the principal functions of the notary public is administering the oath. The low estate of that office in the United States, contrasted with its dignity in Europe, is a product of indiscriminate resort to the oath. Although so cheapened that it gives little assurance against false testimony, the law nevertheless provides that false testimony under oath constitutes the crime of perjury (*q.v.*).

Affirmation.—The principal alternative to the oath as a safeguard against false testimony is the affirmation—the witness declares his intention to tell the truth, under the pains and penalties of perjury. Affirmation was originally a concession to those whose religious scruples prevented the swearing of oaths. It has been extended in Great Britain and in many states of the United States to nonbelievers as well. Members of nonmonotheistic religions are frequently sworn according to the forms of their own faith. Persons of immature understanding may testify without either oath or affirmation if they display understanding of the duty to tell the truth.

Affidavit.—An affidavit is used in judicial proceedings and in perfecting records of factual events. It recites the place in which it is made; that the affiant (or, commonly, deponent), having been first duly sworn, "deposes and says" certain facts; and, in appropriate cases, that he knows nothing further of the matter—"further deponent sayeth not." It must then be signed by the deponent in the presence of the administering official, who executes thereon his jurat. In the jurat he recites that the instrument was executed before him, under oath, giving the date thereof; he states his authority to administer oaths; and he impresses thereon the seal of his office. The purposes are two: the formalities give some assurance that the instrument is genuine; and the oath gives some assurance that the statement is true as well as genuine. Because not made subject to cross-examination, however, the law courts normally decline to receive it in lieu of oral testimony except in interlocutory proceedings. Were the affidavit made subject to cross-examination, however, it would in the United States be called a deposition and would be more freely receivable. Depositions are now freely used in the U.S. when the deponent is unavailable. In Britain the Evidence act, 1938, permits freer use of various kinds of written evidence, including affidavits, in proper cases, by leave of the court. *See* also EVIDENCE; LOYALTY.

See H. Silving, "The Oath," *Yale Law Journal*, 68:1329–1390 and 1527–1577 (June and July 1959). (R. E. DE.)

OATS. The oat plant belongs to the genus *Avena* and is one of the important cereal crops. The grain is used largely as feed for livestock, although some is processed directly into food for human beings.

Origin.—Wild oats were first found growing in different regions of western Europe. Early writers stated that oats were found as a weed mixed with barley and therefore may have been distributed as a mixture in barley. From western Europe oats spread to other temperate parts of the world and are produced under a wide range of conditions. It was previously thought that cultivated oats were derived chiefly from two species, the common wild oat (*Avena fatua*) and the wild red oat (*A. sterilis*). Some cereal workers held that common white oats (*A. sativa*) were derived from *A. fatua* with a spreading panicle and that red oats (*A. byzantina*) came from *A. sterilis*. Later some workers believed that *A. sterilis* was the progenitor of both the red oats and white oats.

Botanical Description.—The flowering and fruiting structure of the oat is a terminal panicle that is usually lax or spreading. In some rare types, the panicle is reduced so that it approaches the spikes or heads of other small grains. The panicles may be either approximately symmetrical or with a preponderance of branches and their terminal spikelets hanging to one side, producing what is called side oats. The panicle is made up of numerous branches and spikelets, which in turn are composed of two papery glumes and usually two florets. The primary and secondary florets are held together by a short, thin rachilla. The individual floret has a lemma and palea that enclose three stamens, a pistil and two lodicules.

After fertilization the pistil develops into a one-seeded fruit called a caryopsis. The fruit, also called the groat, is closely clasped by the lemma and palea except in hull-less types where it is freed upon threshing. In *Avena nuda*, a naked species, spikelets may have five to ten florets, borne on long rachillas.

The lemma and palea, the covering or hulls containing the groat are usually without hairs in most cultivated oats (*Avena sativa*). In a large number of the wild forms, however, the lemma is covered with numerous hairs. The lemma has a weak awn in many cultivated varieties and sometimes a large and twisted awn in wild types. The hull colour at maturity may vary considerably from yellow to white, black, brown or red. In some wild species of oats, empty glumes remain attached to the panicle branches after the kernels have fallen to the ground. In cultivated species, however, most of the kernels remain attached until threshed. The basal articulation of the spikelet is useful in species classification. Sometimes the secondary kernel is tightly clasped by the lemma of the primary kernel; this is known as doubling or bosom kernels. Sometimes the first flower may be sterile and yet not doubled. The caryopsis or groat weighs about 20 mg. and the lemma and palea about 6 mg. in cultivated oats. The oat panicle usually is from 4 to 21 in. long and may have as few as 8 to 10 kernels or as many as 200, and averages about 45 kernels. When an oat seed germinates, the scutellum (part of the germ adjacent to the endosperm) elongates; this is in contrast to other cereals.

The leaves of the oat plant are thin, narrow and long. They are very prominent in the early phases of growth, but become less prominent upon maturity, at which time the culms elongate and produce the stalk or culm of the plant. The base of the leaf blade has no auricle, this being in contrast to other small grains. The

PANICLES OF OATS

Stems are usually hollow except at the nodes. Culms are from two to five feet tall and the number per plant depends largely upon the rate of sowing, the fertility of the soil and growth conditions. Roots are fibrous and numerous, and penetrate the soil to various depths.

Classification.—The genus *Avena* is composed of a polyploid series, as is true of *Triticum* (wheat), the haploid (*n*) chromosomes numbering 7, 14 and 21 in the sex cells, or 14, 28 and 42 in the vegetative or diploid (*2n*) cells. These are called diploid, tetraploid and hexaploid groups respectively. Several diploid species are recognized and at least two tetraploid species. The hexaploid group contains the commonly cultivated varieties including *Avena byzantina*, red oats. Hull-less and wild forms are in this series. I. Nishiyama has experimentally produced stable octaploid types with 56 (*2n*) chromosomes.

The common wild oat is distributed in cooler areas of the world as well as warmer sections like Mexico. Hexaploid and tetraploid wild species are sometimes grazed or cut for hay. Because the seeds may lie dormant for long periods wild oats are difficult to eradicate. Kernels at the top of the panicle mature sooner and drop to the ground as they ripen, even though the culm may still be green. The panicle of the wild oat is usually longer and more lax than that of the ordinary cultivated sorts.

Fatuoids or false wild oats have been observed in nearly all cultivated varieties. Fatuoid kernels also drop to the ground as do wild oats. However, false wild types do not constitute a weed hazard.

The various common oats are grown in cooler and more temperate regions of the world. Side and late-maturing common oats occur in northwestern Europe, northern sections of the United States and southern Canada. The smaller yellow-kerneled varieties occur in southwestern U.S.S.R. and to a lesser extent in the corn belt of the United States. Red oats are grown principally in warmer climates, including the southern sections of the United States, the Mediterranean region and areas of South America and Australia. These are considerably more heat-tolerant than are the common types. Hull-less (*A. nuda*) forms are found in the highlands of Tibet, northern India, Turkestan and western China.

Some of the older agricultural varieties of oats in North America are Kherson, Silvermine, Victory, Fulghum, Red Rustproof, Markton, Columbia, Ajax, the "Victoria-Richland" group and the Bond varieties including Clinton, Cherokee and Nemaha. Some of the newer varieties are Alamo, Beedee, Clintland 60, Garry, Goodfield, Mo. 0-205, Radar, Rodney, Suregrain, and Victorgrain 48-93. Varieties from other sections of the world are Abed Minor, Algerian, Astra, Avon, Ballidu, Belar, Blenda, Eagle, Flamingstreue, Heilshafer, Golden Rain II, Landhafer, La Prevision, Lyallpur No. ..., Maldwyn, Marne, Mauerner Weiss, Minor, Orion III, Red Algerian, Rex, Santa Fe, S. 147, S. 172, Sisu, Stål, Sun II, Victoria and Victory.

Cultivation and Use.—A large part of the oats produced in the United States are sown in the spring. There are three groups of spring-sown oats: those that are midseason to late in maturity; early white and yellow types; and the spring-sown red types that are grown principally in the Great Plains of the United States. There is also a large area of fall-sown oats in the southern section of the United States. Seeding is done in practically all months of the year in various areas of the world.

Oats are less exacting in their soil requirements than are other cereals with the exception of rye. They seem to be able to extract elements from the soil that would not be available for wheat and barley. In the presence of sufficient moisture, oats do comparatively well on soils that are sandy and low in fertility and on soils high in acidity, but will also do well under fertile conditions. The however, will produce crops on soils that are too poor for satisfactory oat production. In the corn belt of the U.S. oats are grown widely in rotation with corn and forage crops. Oats are used as a nurse crop with grasses and legumes that are to be used later for forage purposes. Since oat culture is relatively simple, a good crop may be obtained by either disking or plowing in the fall or spring, followed by sowing seed with a grain drill or a broadcast seeder. The rate of seeding is about ten pecks to the acre.

Production in the spring-sown area is usually greater when seed is sown soon after frost has left the ground. The combine is widely used for harvesting the crop. Another method is the use of a binder followed by shocking the bundles and then threshing by means of a separator. In some countries harvesting is done by more primitive means.

About 90% of the U.S. oat crop is used for feed. It is fed to all classes of livestock as grain in pure form or in feed mixtures. The straw is used for animal feed and is excellent for animal bedding. Oats make palatable hay, furnish excellent grazing and make good silage under proper conditions. Oats have long been a favourite source of breakfast food. Rolled oats or oatmeal is used mostly for porridge, although other kinds of breakfast foods are manufactured from the groats. Oat flour is also used in cookies, breads and puddings. The flour contains an antioxidant that retards development of rancidity in fat-containing foods.

The oat grain is high in protein and fat content. It is also a very good source of vitamin B_1 and has appreciable amounts of the other B vitamins including riboflavin, niacin, choline, pantothenic acid and vitamin E. It is practically devoid of vitamins C and D. Leaves of growing young plants are high in a large number of nutritional elements that add to its value as fodder.

The oat crop enters industrial usage to a small extent. One of the principal industrial products is the liquid aldehyde called furfural (*q.v.*). This is made by the destructive distillation of oat hulls, corncobs and other agricultural residues in the presence of acid and steam under regulated conditions. Furfural is used in selective solvents for various purification purposes, in paint remover, lacquer solvents and in adiponitrile, which in turn is used in developing nylon. Limited medical products come from oats.

In most regions of the world, oat culture faces the hazards of rust, smut, viruses, fungal rot (that is, *Septoria*) and other diseases that may greatly reduce yield and quality. Plant breeders try to develop oats that are resistant to these major diseases and that are high in quality and yield. In certain areas drought resistance and the survival of fall-sown varieties are much-needed characteristics sought by the plant breeder. Inasmuch as oats are self-pollinated and breed true after pure lining, improvements are easily utilized in production increase. New and superior varieties are developed by means of hybridization followed by purification and testing against standard varieties.

One of the main problems in breeding is the selection of plant progenies in early generations that will resist disease and have high productive capacity. Specialized races of pests including viruses and pathogenic fungi complicate the problem of breeding for disease resistance. Much progress was made, especially after about 1930, in breeding oats with smut and rust resistance. In addition better grain quality and much stiffer straw was obtained. Lodging-resistant varieties enabled farmers to obtain greater yields with higher soil fertility levels and with less trouble at harvest. Breeders have induced genetic variability with chemicals and irradiation. Florad was the first variety resulting from irradiation breeding to be distributed, by the Florida Agricultural Experiment station.

Production.—The estimated annual world production of oats in the 1960s was more than 4,000,000,000 bu. on about 80,000,000 ac. Production has remained fairly steady, while acreage has declined. The leading producing countries are the United States, U.S.S.R., Canada, France, Poland, the United Kingdom and West Germany. Substantial quantities also are grown in Australia and New Zealand.

Improved varieties have permitted increased yields per acre. In the United States, for example, production averaged 35.7 per acre for the period 1949–58. In the 1960s yields averaged more than 40 bu. per acre, with some farmers growing 80–100 bu. per acre in cool seasons and more than 150 bu. per acre with irrigation. The competition of hybrid corn and longer-lived alfalfa has tended to reduce the demand for oats.

Bibliography.—For further reading and comprehensive treatment of oats *see* F. A. Coffman (ed.), *Oats and Oat Improvement;* Monograph of the American Society of Agronomy, Madison, Wis. (1961),

which contains discussions of world importance and distribution, breeding accomplishments, diseases, culture in North America and processing and composition. For oat species and variety description *see* T. R. Stanton, "Oat Identification and Classification," U.S. Department of Agriculture *Technical Bulletin 1100* (1955). (H. L. Ss.)

OAXACA, a southern state of Mexico that includes the greater part of the Isthmus of Tehuantepec (*q.v.*) on its Pacific side. Pop. (1960) 1,727,266, the majority of whom are Indians divided into more than 15 major tribes. Area 36,820 sq.mi. The capital city, also named Oaxaca (*q.v.*), is near the centre of the state on a high plateau surrounded by mountains. The Sierra Madre del Sur ends at the Isthmus of Tehuantepec, which is low, hot and arid. The Atlantic lowlands near Veracruz are hot and humid, but most of the state enjoys mild, healthful conditions in its broad valleys and fertile uplands. The Pan-American highway from Mexico City traverses the state southeasterly, while rail lines from Coatzacoalcos on the Gulf of Mexico to the Pacific port of Salina Cruz and trunk lines from Puebla and Veracruz form an incomplete rail net within the state. There are good air connections, and the free port of Salina Cruz has large dry docks.

Oaxaca is an agricultural and mining area, with a broad range of products, chief among which are maize, wheat, coffee, sugar, tobacco, fibres and tropical fruits. It manufactures for local consumption cigarettes, soap and Indian blankets, or serapes, from wool. Its mountains are veined with gold, silver, uranium, diamonds, onyx and other deposits. During colonial days Oaxaca was a notable producer of silk and of cochineal for dyestuffs.

In pre-Columbian times the Zapotecas and Mixtecas constructed stone edifices, the remains of which are found at Mitla and Monte Albán; the descendants of these Indians form the majority of the population. *See* also MIXTEC. (J. A. Cw.)

OAXACA (OAXACA DE JUÁREZ), capital city of the state of the same name in Mexico, stands in the fertile valley of Oaxaca at an altitude of 5,070 ft. Pop. (1960) 72,370. The Pan-American highway, continuing south from Mexico City, passes through Oaxaca on the route to Guatemala. A beautiful colonial city, Oaxaca is noted for its 16th-century art and architecture as well as for the delicately coloured green stone used in many buildings. Nearby are the Mixtec ruins of Mitla and the Zapotec ruins of Monte Albán. Oaxaca has one of the most colourful handicraft markets in Mexico, selling multicoloured glazed pottery, black pottery ware, leather goods, fine steel knives, gold filigree jewelry and hand-woven wool and cotton textiles. Founded in 1486 as an Aztec garrison post and conquered by the Spanish in 1521, Oaxaca has played an important part in Mexican history and was the home of two of Mexico's most famous presidents, Benito Juárez and Porfirio Díaz. (H. R. Hy.)

OB, a river of Siberia, U.S.S.R., is one of the largest in the world. The Ob from the confluence of the Biya and Katun is 2,287 mi. long. With its largest tributary the Irtysh (*q.v.*), itself 2,640 mi. long, it forms a river 3,461 mi. in length. Its basin covers an area of about 1,131,000 sq.mi., within which are several basins of inland drainage, forming more than 15% of the total area. The Biya and Katun rivers, which form the Ob, drain from the Altai mountains and meet at Bisk. Thereafter the Ob flows west and then north to Barnaul. This part of its course is highly braided, with many sand and shingle banks. Below Barnaul the Ob again flows west and north through the Novosibirsk reservoir to Novosibirsk. After 1962 a second great barrage and power plant was constructed at Kamen-na-Obi on this stretch. At Novosibirsk, the largest city of Siberia and the crossing point of the Trans-Siberian railway, the Ob leaves the low Altai foothill zone and enters the vast west Siberian lowland. It flows in a highly sinuous course over a wide floodplain with innumerable channels, cutoffs and oxbow lakes, in a general northwesterly and westerly direction to the confluence with its giant tributary, the Irtysh, at Khanty-Mansisk. The river itself in this section is up to 2 mi. wide. Below Khanty-Mansisk the Ob flows in a general northerly direction to Salekhard, where it swings east to enter the head of the Ob gulf of the Kara sea, by a delta. From Peregrebnoye to just above Salekhard, the river divides into the Great and Little Ob, with innumerable connecting channels. At Salekhard the river is about 2½ mi. wide. The Ob gulf (Obskaya Guba), more than 500 mi. long and about 50 mi. wide, represents the drowned lower course of the Ob.

The greater part of the Ob basin is extremely level lowland and below the Tom confluence the fall of the Ob is about 1 in 40,000. The rate of flow is thus very sluggish. The annual average discharge is 441,434 cu.ft. per second with a maximum at Salekhard of 1,292,420 cu.ft. and a minimum of 79,458 cu.ft. Maximum flow comes in March–May in the upper reaches and April–June in the lower. Ice first appears about mid-October in the lower course and late October in the upper, with a firm ice cover established 8–10 days later, although shallows often take longer to freeze over. The spring breakup of ice begins first in late April, in the upper reaches, causing huge ice jams and widespread flooding. Navigation is possible along the entire river, and north of Tomsk it is the only important means of communication. Until the building of the Trans-Siberian railway the Ob and Irtysh formed the main route across western Siberia. The main tributaries are the Irtysh, Vasyugan (457 mi. long) and Severnaya (Northern) Sosva (447 mi.) on the left, and the Chulym (1,077 mi.), Ket (845 mi.) and Tom (522 mi.) on the right. (R. A. F.)

OBADIAH, BOOK OF, in the Old Testament, the fourth of the Minor Prophets in the Hebrew, Latin and English order and the fifth in the Septuagint Greek. The name, which means "worshiper of Yahweh," is transliterated OBDEIOU in Codex Vaticanus and ABDIOU in Codex Sinaiticus of the Septuagint and ABDIAS in the Vulgate.

Contents.—The book, which consists of only one chapter, may be outlined as follows:

1–14:	judgment of Edom
1a:	title
1b–4:	warning of Edom's downfall
5–9:	complete destruction of Edom
10–14:	reasons for judgment of Edom
15–16:	judgment of all nations
17–21:	restoration of Israel

Main Themes.—*Revelation.*—The phrase "says the Lord" or its equivalent occurs four times (1, 4, 8, 18). Belief in a living God who reveals his will is a basic tenet of prophetic religion.

Judgment.—The main message of this book is God's moral judgment through the events of history. Despite its vaunted fortresses and wisdom, Edom has been pushed out of its original land and will be destroyed because of cruelty to its brother-nation Israel. Israel also has been punished by conquest and captivity. Finally on the day of the Lord all nations will be judged.

Nationalism.—Obadiah has been accused of nationalism because he pronounces doom on Edom, Israel's enemy, and looks forward to the restoration of his own people. His primary loyalties, however, are not to land or race but to moral principles and to God.

The Kingdom of God.—The ultimate hope of Obadiah is that "the kingdom shall be the Lord's" (21; *cf.* Rev. xi, 15). Two aspects of this kingdom are "deliverance" ("escape") and "holiness" (17), concepts which are spiritualized in the New Testament (*e.g.*, Luke xxi, 36; Rev. xxi, 2–8).

Form and Style.—In form Obadiah follows a common prophetic pattern in dealing first with present sin and judgment (1–14) and then with future judgment and hope (15–21). The vigorous style of Obadiah is marked by varied poetic rhythms and striking comparisons, and contrasts between doom (1–16) and hope (17–21). In much of this brief prophecy God himself is addressing personified Edom (2–15), and this gives a direct and arresting quality to the book.

Date and Authorship.—The compilers of the Hebrew canon placed Obadiah among the pre-exilic prophets. Some scholars have proposed that the background for the whole book was the attack of the Arabians and Philistines on Judah in the 9th century B.C. (II Chron. xxi, 16–17). Many commentators think that only the old oracle against Edom (1–6, 8–9) is pre-exilic. But the calamity to Jerusalem in 11–14 is probably its capture in 587 B.C. by the Chaldeans, assisted by the Edomites (*cf.* Ps. cxxxvii, 7; I Esdras iv, 45). In the later 6th or early 5th century B.C., Arabs pushed Edomites into the Negev, as implied in Obad. 7, Mal. i, 3–4 and I Esdras iv, 50. According to Obad. 19–20, the returned Jews occupy the area around Jerusalem, as in the mid-5th century B.C. (

Neh. xi, 25–36), which is the probable date of the prophecy in substantially its present form. If, then, the prophet Obadiah lived in Judah in the 5th century B.C., he cannot be identified with Ahab's steward called Obadiah (I Kings xviii, 3–16) as in the Babylonian Talmud (*Sanhedrin* 39b), nor with Ahaziah's unnamed captain (II Kings i, 13–15) as in *The Lives of the Prophets* wrongly attributed to the Church Father Epiphanius. Apart from 1–6 and 8–9, where most scholars believe that he adapted an older oracle, the prophecy may well come from Obadiah in its entirety, although some wish to divide 10–21 among various authors. The many identical phrases in different order in Obad. 1–9 and Jer. xlix, 7–22 probably indicate that both prophets are using some earlier oracle against Edom. Several phrases are common to both Obadiah and Joel, and Joel ii, 32 seems to quote Obad. 17 directly.

Geographical References.—Rabbinic commentators sometimes interpret Edom as Rome or Christendom. "The rock" (3) probably refers in general to the mountainous home of the Edomites and also in particular to the Edomite capital Sela ("rock"), called in Greek Petra, where the Nabataeans later carved splendid tombs and temples out of the variegated rock. Teman (9) may be modern Tawilan, 5 mi. E. of Petra. Verse 19 foresees a Jewish expansion toward the south, the west, the north and the east, which actually occurred under the Maccabees. Sepharad (20) was interpreted as Spain by the Syriac Peshitta and Aramaic Targum, and hence Spanish and Portuguese Jews are called Sephardim. It is probably, however, Sardis in Asia Minor, where there was a Jewish colony in the 5th century B.C.

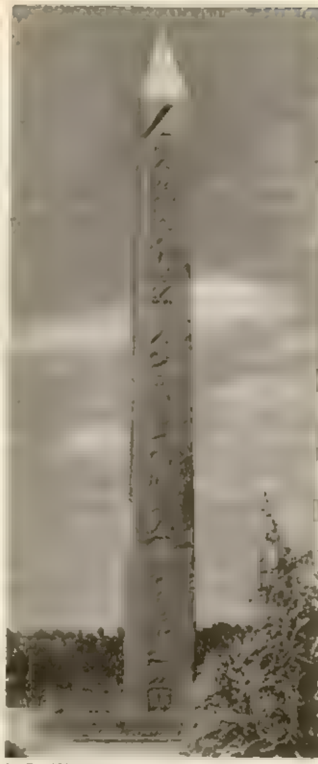
OBANDO, JOSÉ MARIA (1795–1861), president and *caudillo* (military-political leader) of Colombia, was born in the Cauca region of that country. He fought for the Spanish crown during most of the Latin-American war for independence, but finally joined the revolutionary forces under Simón Bolívar. In the turbulent new republic of Gran Colombia, Obando opposed Bolívar's centralist government. A key event in the struggle for power was the assassination of Marshal Antonio de Sucre (*q.v.*), a deed for which many persons have held Obando responsible. Sucre's death helped clear the way for Obando's rise in the 1830s to the vice-presidency and ministry of war in New Granada, as Colombia was then called. In 1838–40, Obando led a revolution against the Conservative party government of New Granada, but he was defeated and fled to Peru. He returned after the election victory of the Liberal party in 1849 and became president of the country in 1853. His regime was marked by the adoption of the liberal constitution of 1853, but he was overthrown the next year by the Conservatives. After a period of exile, Obando returned to Colombia in 1860 and was killed fighting in a civil war. His character and career may be considered representative of the political and military leaders and of the strife which marked the history of Colombia during the 19th century. (T. F. McG.)

OBEID, EL, the chief town of the province of Kordofan, Republic of the Sudan, lies 230 mi. S.W. of Khartoum on a sandy scrub-covered plateau at an elevation of 1,869 ft. Pop. (1965 est.) 62,500. With an encircling forest reserve to mitigate dust storms, El Obeid is laid out on either side of a watercourse in wide straight streets intersecting at right angles. Modern waterworks lie about 10 mi. S. Commerce depends on the railway link eastward (completed 1911), on the more recent extension westward to Nyala and on more than 1,000 trucks operated by local merchants over rough tracks. Commodities of trade are gum arabic, millet, peanuts, melon seeds, cattle and sheep. El Obeid is linked by air services with Khartoum and places in Darfur. Founded by the Turko-Egyptian regime in 1821, El Obeid was captured and largely destroyed by Mahdist rebels in 1882. It was refounded at the beginning of the Anglo-Egyptian condominium in 1899. (J. H. G. L.)



A. F. KERSTING

OBELISK AT AL MATARIYAH, EGYPT

OBELISK, usually a pillar of stone, square in section, tapering upward to an offset pyramidal top. Obelisks seem to have originated in the Egyptian Old Kingdom as grave monuments. In the 6th dynasty a pair was placed at the entrance of the tomb of Sabui at Elephantine and in the 11th dynasty single examples marked the graves of kings at Thebes. These earliest obelisks, which were also used in gardens and in front of palaces, were short (about ten feet at Thebes) and tapered little. The earliest surviving obelisk still in its original position is that of Senusret I (12th dynasty) at Al Matariyah, ancient Heliopolis. It is 68 ft. high and does not taper sharply as do later examples.

Under the New Kingdom, obelisks occupied an important position in temple planning. The 18th-dynasty temple was composed of three main elements: pylon, portico yard and shrine. Such was the plan of the Temple of Amon at Karnak, in which the largest surviving examples still stand. The earliest pair was placed in front of the pylon built by Thutmose I. Of these, one remains in place, over 80 ft. high, 6 ft. square at the base and weighing 143 tons. It celebrates the 30th anniversary of his accession. Queen Hatshepsut added a second, larger pylon and two obelisks 96 ft. high, 5 ft. 4 in. square at the base and weighing 325 tons.

While most of the old obelisks were erected to commemorate jubilees, their real purpose seems to have been connected with sun worship. In a sun temple discovered at Abousir near Giza, the central shrine consisted of a raised platform in the form of a truncated pyramid surmounted by an obelisk. Such obelisks were not monolithic but built up of limestone blocks, and they had sacrificial altars placed in front of them. The Egyptian word for obelisk, *téhen*, is philologically connected with the word for sunbeam. It is known that the pyramidal summits were covered with sun-reflecting electrum (an alloy of silver and gold), and the hieroglyphic sign for obelisk suggests that a golden ball was placed on top of them. A considerable number of small obelisks found at Elephantine originated in the temple of the god Khnum, who by his assimilation as Khnum-Re to the sun-god could display obelisks as symbols of solar religion. Other obelisk dedications are to sun-assimilated gods—Harakhti (at Heliopolis), Amon (at Thebes)—and an obelisk erected by Augustus in Rome bore the dedication "*Soli donum dedit.*"

The sole material for making larger obelisks was the granite of Aswan, where the quarries still hold a large unfinished example. Lesser obelisks were made of basalt or quartzite. Special boats were built for their transport down the Nile.

Close relations between Egypt (*q.v.*) and Canaan in the 12th dynasty led to the adoption of obelisks by Canaanites and Phoenicians. A row of them was found in the temple at Byblos (ancient Gebal), Lebanon, of the early 2nd millennium B.C., and Theophrastus states that at a later date an obelisk of solid turquoise was set up in the temple at Tyre. Obelisks in use by the Assyrians were short and step-topped and designed to bear horizontal reliefs of historical content around the four sides. The most complete example is the "Black Obelisk" of Shalmaneser III (British museum), showing the submission of King Jehu of Israel in the 9th century B.C. (*See* also EGYPTIAN ARCHITECTURE.)

In Greco-Roman Egypt obelisks (*obeliskos*, a "peg" or "needle") were still made. Many were transported to Italy in imperial times

and one to Constantinople by Theodosius I. Copies of obelisks inserted into architectural schemes were already popular in Britain and France in the 18th century. In the 19th century obelisks were taken to London and New York (the two "Cleopatra's Needles," *q.v.*), Paris, Arles, Vincennes and Fontainebleau. The latest obelisks to be constructed in the ancient world were fan-topped monuments at Aksum in Ethiopia. The Washington monument in Washington, D.C., a modern obelisk over 555 ft. high, has an observatory at the 500-ft. level which is reached by interior elevator and stairs. *See* also MONUMENTS AND MEMORIALS.

OBERAMMERGAU, a village in Bavaria, Germany, 42 mi. S.S.W. of Munich. Pop. (1961) 4,603. The village is famous for its wood-carving industry and the performance of the Passion play every ten years.

In 1633 Oberammergau was stricken by the plague. As an expression of their gratitude for the end of the scourge, the villagers vowed to enact the Passion of Christ every ten years. In 1634 the first performance of the Passion play took place. After 1674 the dates were changed so as to fall on decimal years. From 1680 on, the play was given regularly every ten years. In the 1770s a crisis arose when the performance of religious plays was forbidden throughout the electorate. An appeal of the players to the elector Karl Theodor brought about the lifting of the ban. After World War I the production that should have been mounted in 1920 was postponed until 1922. During World War II no performances could take place: most of the villagers were in the German army, and the Nazi regime frowned upon the staging of religious plays. Performances were resumed in 1950.

It takes almost eight hours to perform the play, which is divided into episodes. After a prologue the action begins with Christ's entry into Jerusalem. After Christ's capture on the Mount of Olives falls the intermission. The second part begins with Christ's appearance before the high priest Annas and ends with the Resurrection. Each episode is introduced by a song of the Passion chorus of 50 singers. Moreover, a pantomime tableau presenting the Old Testament prefigurations precedes each episode. Thus the scene with Christ before Pilate is introduced by a tableau showing Daniel before King Darius.

The text of the original Passion play as it was produced in 1634 seems to have been a conflation of two earlier versions of the sacred story, of the so-called Augsburg Passion and of the Passion written by the Augsburg Meistersinger Sebastian Wild. In 1680, however, the text was altered by Johann Aelbl. A new version made by Father Ferdinand Rosner was used in 1750 and 1760. For 1780 Magnus Kipfelberger made alterations. In 1811 a new version was ready, this time prepared by Othmar Weiss. For the performance of 1860 Alois Daisenberger served as play doctor. The text as it stands today has no traceable relation to any authentic medieval text and may well be lacking in literary merits.

Nor is medievalism a feature pronounced in any of the productional aspects. The vast forestage is an open-air platform on which permanent architectural elements are set up. In central position rises a curtained picture-frame stage with wings and backdrops. Next to this inner stage of shifting scenes there are, on either side, gates through which the spectator looks into the streets of Jerusalem. Both gates are flanked by palaces, that of Annas at stage left, and Pilate's at stage right. In extreme downstage position there are smaller gates for side entrances on either side. An orchestra pit accommodates the musicians. The audience is seated in a roofed auditorium which holds 5,200 spectators.

Both the text and the stage are hybrid forms and far removed from medieval prototypes. But the spirit in which the Passion of Oberammergau is presented is still in the medieval tradition which demands that an entire community become involved in the undertaking for the glory of God and the edification of the faithful. A Passion play committee supervises the preparations for the production. The amateur actors are chosen from among the inhabitants of the village, and it is a task of some magnitude to select suitable performers for the 124 speaking parts. Hundreds of villagers are employed in the crowd scenes.

The most famous interpreters of Christ were Josef Mayr, from 1870 to 1890; Anton Lang, in 1900, 1910 and 1922; and Alois Lang (no relation to Anton) in 1930 and 1934. (A. M. N.)

OBERHAUSEN, a city of Germany in the *Land* (state) of North Rhine-Westphalia which after partition of the nation following World War II became part of the Federal Republic of Germany. Pop. (1961) 256,773. It is on the Rhine-Herne canal and is part of the Ruhr industrial belt. Oberhausen, an important rail junction on the main line between Hanover and Berlin, also has good *Autobahn* communications with the Netherlands. It is the centre of a network of lines radiating into the Westphalian coal and limonite iron-ore fields which were the foundation for its rapid industrial development; this began in the mid-19th century with the establishment of a railway station (named after the old castle Oberhaus on the banks of the Emscher) on the uninhabited but mineral-rich Lipperheide.

Oberhausen became a city in 1874 and in 1929 it incorporated the neighbouring towns of Sterkrade and Osterfeld. Economic activities are governed by heavy industry based on the production of pig iron, steel and bituminous coal. The St. Antony ironworks (1758–1876) was the first to be built in the Ruhr. There are also zinc smelting refineries, dye works, railway workshops and a large thermoelectric plant, and manufactures include steam boilers, wire rope, glass, chemicals, sugar, porcelain and soap.

Historic sights include Sterkrade abbey (1150), Holten fortress (1307) and the 16th-century moated castle of Vondern. Among the notable modern buildings are the Rathaus (1930), the main railway station (1938), Euripahaus (1956–57) and a notable modern Stadthalle (city hall; 1962), used for conferences, concerts, exhibitions, etc. Oberhausen is well endowed with schools and has a civic theatre and several art galleries. It is the scene of the annual West German International Short Film festival.

OBERLIN, JOHANN FRIEDRICH (1740–1826), Alsatian Lutheran pastor and philanthropist, devoted his life to transforming his desperately poor parish of Waldersbach and neighbouring villages in the Steintal (Ban de la Roche, Vosges, France) into a materially as well as spiritually flourishing community. He was born of middle-class family at Strasbourg on Aug. 31, 1740, studied theology at Strasbourg university and became pastor of Waldersbach in 1767.

To raise the standard of living in the Steintal, Oberlin first of all started schools in the villages and provided one of the earliest systems of supervision and instruction for very small children while their parents were working. His teaching methods related instruction closely to practical needs and in many ways foreshadowed Pestalozzi and Froebel. He maintained close personal contact with all his parishioners, and his success with the young gradually won the interest of the older generations, who also began to come to him for instruction. Thus Oberlin found men to build roads and bridges, to end the isolation of the Steintal. He encouraged experiments in improving crops and started regular meetings for the discussion and exchange of agricultural information. Better implements were bought in bulk and sold at cost price while a saving and lending bank was founded to help with the initial cost. At his own expense Oberlin sent young men to Strasbourg to learn crafts and had one of his assistants trained as a doctor. Finally, with the help of J. L. Legrand, he started up a small local industry. He died at Waldersbach on June 1, 1826.

Oberlin was strongly influenced by pietist and philanthropist thought, and he admired Rousseau and Swedenborg. His preaching combined rationalism with apocalyptic mysticism. He welcomed the French Revolution and maintained his religious teaching by turning church services into club meetings. Both Revolutionary and imperial governments of France honoured him for his work

Oberlin gave his name to the town and college in Ohio (*see* OBERLIN) and to the Oberlinhaus, a German home famous for its treatment of the deaf, dumb and blind.

See H. Strohl, "Études sur J. F. Oberlin," *Cahiers de la Revue d'histoire et de philosophie religieuses* (1926); W. Heinsius, "Johann Friedrich Oberlin," *Alemannisches Jahrbuch* (1955).

OBERLIN, a city of Lorain county, O., U.S., is located 34 mi. W.S.W. of Cleveland; the seat of Oberlin college. The community was founded in 1833 by the Rev. John Jay Shipherd, a Presbyterian minister, and Philo Penfield Stewart, a former missionary to the Choctaw Indians. In 1834 they also established the Oberlin Collegiate institute to educate ministers and schoolteachers for the west; the name was taken from Johann Friedrich Oberlin, the Alsatian pastor and philanthropist. In the antislavery agitation then current in the North a group of students at the Lane Theological seminary in Cincinnati left that institution in protest against its lack of support of antislavery; the Tappan brothers, merchants in New York, promised to finance their later education under the instruction of Charles G. Finney (*q.v.*), by that time a well-known evangelist, in a college which would appoint him to its faculty. He was given a professorship at Oberlin in 1835 and also served as president from 1851 to 1866. The institute (officially designated a college after 1850) was identified with various innovations: it was coeducational, it admitted Negroes on an equal footing with whites and it became a station on the Underground Railroad by which fugitive slaves escaped to freedom in Canada. In 1858 students and townspeople rescued a Negro at Wellington, 8 mi. S., from law officers who were returning him to his legal owners. As a result some of the "rescuers" were imprisoned in the county jail in Cleveland and the case attracted nationwide attention. The seminary became the graduate school of theology in 1915. Charles Martin Hall, an alumnus who had developed a cheap method of making aluminum commercially, bequeathed to the college several million dollars for the endowment and the construction of Hall auditorium.

Oberlin college includes a college of arts and sciences and a conservatory of music (1867) which maintains a branch in Salzburg, Aus. Discontinuance of the graduate school of theology was announced in 1965. The community, which continues to be primarily a home for the college, was incorporated as a village in 1846 and as a city in 1950. It established a council-manager form of government in 1926. For comparative population figures *see* table in OHIO: *Population*. (R. S. FR.)

OBERMAIER, HUGO (1877–1946), German archaeologist and Roman Catholic priest whose work in Spanish prehistory is especially notable, was born in Regensburg on Jan. 29, 1877. At the University of Vienna he published monographs on central European prehistoric sites, leaving (1910) to take the chair of geology and paleontology at the Institut de Paléontologie Humaine in Paris. He excavated in Bavaria and undertook cave explorations and excavations in Spain, with such men as H. E. P. Breuil (*q.v.*). In 1922 Obermaier became professor at the University of Fribourg, Switz., where he died on Nov. 12, 1946.

He published *Der Mensch der Vorzeit* (1912), *El Hombre fosil* 1916; Eng. trans., *Fossil Man in Spain*, 1924), *The Cave of Altamira* with Breuil in 1935 and many monographs on Spanish prehistory. He also collaborated in publications of African prehistoric art, notably *Hadschra Maktouba* (1925) with L. Frobenius.

See H. Breuil, "Hugo Obermaier (1877–1946)," *Revue Archéologique*, vol. 35 (1950). (H. KE.)

OBERON, the name given to the "king of faërie" in the French medieval poem *Huon de Bordeaux* (*q.v.*), and introduced into English literature by the prose translation (*c.* 1534) by Lord Berners (*see* BERNERS, JOHN BOURCHIER). In the French poem, Oberon is a dwarf-king, living in the woodland, who by magic powers helps the hero to accomplish a seemingly impossible task—a common theme in folklore, from which Oberon (though not under that name) ultimately derives. He can be equated with Alberich, the dwarf who guards the underground treasure in the Germanic Siegfried legend, only in that both probably originated in prehistoric belief in a powerful spirit guarding the burial mounds in which, with the bodies of the dead, their valuable possessions were interred.

The first English writer to mention Oberon was Robert Greene, in his play *The Scottish Historie of James the fourth* (*c.* 1590–91; publ. 1598). Shakespeare's Oberon in *A Midsummer Night's Dream* (*c.* 1593–96) derives many elements from the French, via Lord Berners. His fairy queen, Titania, however, is taken direct from Ovid's *Metamorphoses* (book III, line 173), where the goddess Diana is called Titania; *i.e.*, daughter of the Titans. Among later poets to describe Oberon as a fairy king or prince were Ben Jonson (*q.v.*), in his court masque *Oberon, the Faery Prince* (performed Jan. 1, 1611), and Michael Drayton in his charming fairy poem *Nymphidia* (1627). Shakespeare's Oberon inspired the German poet Christoph Wieland, whose romantic epic *Oberon* (1780), in the English translation of 1798, formed the basis of J. R. Planché's libretto for Carl von Weber's opera *Oberon* (Covent Garden, 1826).

OBERTH, HERMANN JULIUS (1894–), a founder of modern astronautics, was born June 25, 1894, in Hermannstadt, Transylvania, then a part of the Austro-Hungarian empire. The son of a prosperous village physician, he early displayed an interest in mechanical and scientific subjects. In 1913, bowing to his father's desires, he enrolled in medicine at the university in Munich but managed to continue taking courses in mathematics and astronomy. His university career was cut short by World War I, and Oberth enlisted in the Austro-Hungarian Army. After being wounded in battle, he was transferred to the Medical Corps, in which he had time to continue his studies in astronautics. He performed experiments to simulate the feeling of weightlessness and also worked out a design for a long-range, liquid-propellant rocket that his commanding officer sent to the War Ministry, which rejected it as a fantasy.

After the end of the war, Oberth spent several years at universities studying science and mathematics. At Heidelberg, he sought a Ph.D. degree with a dissertation based on his rocket design of World War I. The dissertation was rejected by the university in 1922, and Oberth submitted it to a series of publishers. It was published in 1923 but only after Oberth had partially underwritten the expenses.

The book, which explained mathematically how rockets could achieve a speed that would allow them to escape the earth's gravitational pull, was an immediate success, and Oberth gained widespread recognition. He did not become familiar with the work of Robert Goddard in the United States until 1922 and Konstantin Tsiolkovski in the U.S.S.R. until 1925. Corresponding with these two pioneers in rocketry and astronautics, he acknowledged their precedence in deriving the mathematical equations associated with space flight.

In 1929 Oberth's book *Wege zur Raumschiffahrt* ("Way to Space Travel") won the first annual Robert Esnault-Pelterie–André Hirsch Prize of 10,000 francs, which helped him to finance his research in liquid-propellant rocket motors. The book was remarkable for its discussion of electric propulsion and the ion rocket, anticipating the efforts to develop them by 30 years. With little encouragement from government or industry but with the enthusiastic support of space travel enthusiasts, Oberth continued to develop his theories of manned space travel as World War II approached. In 1938 he joined the faculty of the Technical University of Vienna and in 1940 he moved to the Technical University of Dresden. During that year he became a German citizen and in 1941 he transferred to the German rocket development centre at Peenemünde, to work for his one-time assistant, Wernher von Braun. However, his talents were little used, and in 1943 he was sent to another location to work on solid-propellant antiaircraft rockets.

After the war Oberth spent a year in Switzerland as a rocket consultant, and in 1950 moved to Italy, where he worked on solid-propellant antiaircraft rockets for the Italian Navy. In 1955 he moved to the United States, where he engaged in advanced space research for the U.S. Army. He returned to Germany in 1958 to spend his retirement writing and lecturing. (M. R. S.)

OBESITY is that physical state in which excessive fat is

stored in the body. Though it is often considered primarily a cosmetic defect, making the obese person less attractive than the person of normal weight, obesity deserves the consideration accorded to serious disease. The disorder indicated by obesity is a prolonged positive energy balance, with resultant excess accumulation of fat and formation of superfluous adipose tissue.

In obesity there is excess deposit of fat in both normal and abnormal sites. In extreme cases the subcutaneous fat may exceed ten centimetres in thickness. Large amounts of fat may be found in the membranous tissues that enclose the abdomen (retroperitoneal space, omentum and mesentery), in the tissues surrounding the kidney, in the space between the lungs and in the pericardium (the membranous sac that contains the heart). Fatty infiltration may occur in the pancreas, in skeletal muscles and in the heart muscle. The liver may be greatly enlarged, and many of its cells may be filled with fat.

Diagnosis.—Although adiposity is usually evident from appearance alone, appearances may be deceptive. Some persons who are overweight by the usual standards have exceptionally heavy muscle development and are not fat. Others may be within the normal weight limits, but their bodies may contain excessive fat and be deficient in muscle. The diagnosis of obesity is simply the first step; it is necessary to establish also the ideal weight of the subject and the degree of obesity. Approximate optimal weights according to height, sex, age and type of body frame may be found in tables (see *Bibliography*). Weights given in such tables, however, are approximations and are not necessarily applicable to any single person; they give mean or average weights. More accurate optimal weights for each person can be determined by individual application of one or more methods:

1. Skeletal measurements of wrist circumference, knee circumference, shoulder width, hip width, etc. Such measurements permit calculations based upon the width and depth of the body and the size of the skeletal framework.

2. Densitometry, a more exact method of measuring fat storage as compared with normal, requires the determination of the specific gravity of the whole body by weighing the person under water. Since human fat has a density of 0.92 whereas the rest of the body has an average density of 1.1, the percentage of body fat may be calculated when the total body density is known, correction being made for residual air in the lungs. This is the most accurate method of calculating body fat content, but the difficulties involved limit its use to research laboratories.

3. Measurements of total body water (by dye dilution and other chemical techniques). Under normal conditions total body water maintains a constant relationship to lean body mass. When total body water is known, lean body mass can be calculated and the fat content of the body determined by subtracting lean body mass from total body weight.

4. Skin-fold thickness. Formulas have been devised for estimating body fat content by calculating from careful caliper measurements of skin-fold thickness at several specified points on the body.

Many useful data have been developed from studies utilizing these methods. In an average healthy young man, fat constitutes about 15% of the total body weight, extracellular water about 23%, cells or active tissue 58% and bone mineral 4%. In obesity of extreme degree the percentage of fat may exceed 50 and even reach 70. In extreme leanness, the percentage of body weight made up of fat may be lower than 10, even as low as 2. Normal young men of the same heights and ages as a group of young women had average body fat content of 9.8% as compared with 17% for the women. Even when weights are the same, normal middle-aged men are much fatter than normal young men if body content of fat is used as the criterion rather than height-weight-age tables. The trend for older as compared with younger females is similar, but females are fatter than males at all ages.

Computation of actual individual body fat content can be very helpful, but for practical purposes in most cases, accurate weighing of the unclothed fasting person (before breakfast), careful physical examination and comparison with ideal weight figures from the standard tables suffice to establish the diagnosis of obesity and its degree. Tables giving average rather than desirable weights at various ages and heights are misleading, for the optimal weight of an adult remains unchanged but average weights increase in the middle decades. Even minor degrees of corpulence (*i.e.*, 10% to 15% above optimal weight) are accompanied by higher mortality rates.

Incidence.—Obesity occurs frequently even among children and adolescents, but it is commoner among adults. Moderate corpulence affects about one-fifth of the adult population of the United States, occurs most frequently between ages 30 to 50 years, and is somewhat commoner in women than in men. In the United States it is estimated that about 9% of the population is 10% overweight and 3% is 20% overweight.

Consequences.—Obese persons suffer more often from a number of illnesses than do persons of normal weight, and they also have a shorter life expectancy. The hazard of obesity increases with age, so that persons 45 to 50 years old who are 10 lb. overweight have an increase above the average death rate of 8%; those 20 lb. overweight, 18%; and so on. Analysis of the causes of death among obese persons as compared with those among persons of normal weight reveals that deaths from degenerative diseases of the heart, the arteries and the kidneys account for the greatest proportion of the higher mortality. All types of cardiovascular-renal conditions appear to occur more frequently and with greater severity among overweight persons, including, in particular, heart failure, cerebral hemorrhage and thrombosis, coronary thrombosis and nephritis. More of the obese die of accident, probably because fat people are less agile than thin people. The death rate from diabetes is almost four times as great among obese persons as compared with those of normal weight. Other diseases that occur more frequently in the obese are cirrhosis of the liver, gallstones, cancer of the liver and gall bladder, cancer of the uterus, appendicitis, complications of pregnancy and the postpartum period, diaphragmatic hernia, degenerative arthritis and flat feet. High blood pressure, varicose veins and venous thrombosis and embolism affect obese persons more severely and appear to occur more often among them. The greater the adiposity, the poorer the chances of success in and survival after surgery.

Because obesity is so common and affects health and life expectancy in such a variety of ways and in such severe and definite manifestations, it has been called the greatest single health hazard.

Causes.—Investigation of developing obesity in its early stages offers hope of discovering specific causative factors. There is of course only one ultimate cause of obesity: a caloric intake persistently exceeding the caloric output. There are, however, many ways in which the energy balance may be tilted to the positive side. Maintenance of normal body weight and of normal fat stores depends upon an outflow of heat and energy equal to the inflow provided by food. Excess food, whether taken as protein, carbohydrate or fat, is chiefly converted into and stored as body fat. In children, when the body is growing and physical activity is high, protein intake and total caloric intake must be high to provide for tissue growth and muscular energy. After body growth is complete, and muscular activity diminishes (as it does in most persons in the middle decades), excess calories taken as food produce not useful body tissue but detrimental fat. Perhaps in the least complex cases of obesity the commonest causes are either simple overeating or lack of exercise or both.

Physiological Factors.—Digestion and absorption of food are not more efficient in obese than in thin persons. Lipophilia (an extraordinary ability of the body to retain fat) has not been demonstrated to be present in the usual types of obesity. Local tissue avidity for fat, however, may be of importance in conditions in which the adiposity has a characteristic distribution, as, for example, in lipomatosis or lipodystrophy or in the condition called Cushing's syndrome. Obese persons do not conserve calories by accomplishing work with less effort and storing the difference. On the contrary, the total metabolism of obese persons is higher than normal, not lower.

It once was thought that the majority of obese persons might have endocrine defects, but this has not proved to be true. In only a minority of cases (perhaps about 5% of all obese persons

disorders of glands of internal secretion are demonstrable, among them hypothyroidism, hypogonadism, hyperadrenocorticism and hyperinsulinism. Underfunctioning of the thyroid gland is rarely the cause of obesity. The thyroid gland function and the basal metabolic rate are normal in the great majority of obese persons. When the sex glands (ovaries or testes) are absent or deficient in function, the subject may become more placid and less active physically and there is a predisposition to obesity, with fat deposits in certain areas: breasts, buttocks, hips and thighs. Formerly hypopituitarism was considered a cause of obesity, but pituitary disorders are not associated with adiposity unless the area at the base of the brain called the hypothalamus (*q.v.*) is impaired. In the hypothalamus are groups of nerve cells concerned with the regulation of appetite. When certain of these centres are damaged in experimental animals appetite is increased and obesity is a consequence unless increased muscular activity is enforced. Fröhlich's syndrome and other types of adiposogenital dystrophy characterized by adiposity and hypogonadism are due to hypothalamic disturbance plus pituitary disturbance, the gonadal deficiency being secondary to pituitary malfunction. Cushing's syndrome and disorders associated with excess secretion of the steroid hormones of the adrenal cortex are characterized by development of a striking "central" type of obesity in which the extremities tend to be spared. Similar adiposity may result from therapy with steroid hormones. Excess secretion of insulin by the pancreas may cause periods of low blood sugar and hunger and thus lead to obesity. (*See* also METABOLISM, DISEASES OF.)

Limitation of energy output from any cause may predispose to obesity. Laziness due to psychogenic factors is a common influence, but obesity also may develop if eating habits persist during periods of enforced inactivity.

Psychological Factors.—Improper childhood training, frustrations, nervous tensions and dissatisfactions may be expressed in increased food intake or decreased physical activity, and frequently both. Pleasure in eating may become a dominant personality trait, serving as a substitute for other satisfactions (social, business, sexual, etc.) that are unfulfilled. Problem children often become obese and use the condition to demand special attention. In the great majority of cases psychological factors are important, but in many instances both psychological and physiological influences favouring a positive energy balance may be discovered. In certain families may be seen hereditary factors that favour the development of obesity. Multiple causative factors are the rule, not the exception.

Symptoms.—Physical symptoms of obesity are fatigue and shortness of breath, and there may be aching in back, knees and feet. Later symptoms may be those of high blood pressure, heart failure, diabetes or other conditions to which obesity predisposes. Psychological results of obesity range from shyness and withdrawal to overly bold self-assertion. Often there are accompanying neuroses or even more severe psychological disorders.

Treatment.—It is better to prevent obesity than to attack the condition after it has reached considerable proportions. Proper eating habits should be established and, unless contraindicated, moderate regular exercise should be encouraged. When obesity is mild and uncomplicated, treatment with a low caloric diet and exercise should be sufficient. When obesity is more severe and causes are complex, treatment may include diet, physical therapy, drug and hormone treatment and psychotherapy.

Treatment has two aims: removal of causative factors and removal of excess stored fat. Removal of causative factors is relatively easy in rare cases only; for example, when a pancreatic islet tumour can be discovered to be responsible and can be removed surgically. Since, however, in the common types of obesity a disorder of appetite control is present, or there is a neurosis of which obesity is only a symptom, attempts to correct causative influences may prove difficult.

Whatever the cause of obesity, restriction of caloric intake in the diet is necessary to induce weight loss. Use of certain drugs under careful medical supervision may help to reduce appetite and ensure better observance of prescribed diets. The diet should allow about 10 calories per kilogram of ideal body weight if the subject is relatively inactive, or 15 to 20 calories per kilogram per day for moderate muscular exercise. Such a diet would allow 700, 1,000 or 1,400 calories per day for persons with ideal weight of 70 kg. (150 lb.). In reduction diets protein allowance usually should be liberal and fat minimal. The carbohydrate allowance should be supplied chiefly in the low carbohydrate bulky fruits and vegetables. Salt restriction may be advisable if fluid retention is present. Supplements of vitamin A and the B complex are advisable if dieting is to be prolonged, since foods containing these vitamins are restricted.

Regular exercise, preferably daily and preferably out-of-doors (such as walking, golf, swimming, etc.), is very helpful in increasing caloric output, but is even more valuable to improve muscular development, general health and morale. *See* also DIET AND DIETETICS; ENDOCRINOLOGY; HEART, DISEASES AND DEFECTS OF; MALNUTRITION: *Overnutrition*; NUTRITION.

OBITER DICTUM, that which is said by the way; an incidental statement. Specifically, in law, it refers to a passage in a judicial opinion which is not necessary for the decision of the case before the court. Such statements lack the force of precedent, but may nevertheless be significant. "In order that an opinion may have the weight of a precedent . . . it must be an opinion the formation of which is necessary for the decision of a particular case; in other words, it must not be *obiter dictum*." Dicta frequently take the form of statements which are unnecessarily broad. Thus when a young man willfully murdered his grandfather to prevent his revoking a will, the court held that the beneficiary was not entitled to the legacy which the will provided for him, saying that the law will not permit one "to take advantage of his own wrong, or to found any claim upon his own iniquity, or to acquire property by his own crime." In a subsequent case, involving a legatee who had negligently caused the testator's death in an automobile accident, the same result would not necessarily follow; the court would be free to distinguish the cases on their facts and limit the broad dictum of the earlier case.

(B. CE.)

OBLATE (Lat. *oblatus*, "offered"), an ecclesiastical term for lay persons not professed monks, friars or nuns who have devoted themselves to follow the ideals of a religious rule of life. Formerly oblates also included children who were dedicated by their parents to a religious life.

"Oblate" is also familiar in the Roman Catholic Church as the name of a religious congregation of priests, the Oblate Fathers of St. Charles. This congregation was founded in 1578, under the name of Oblates of the Blessed Virgin and St. Ambrose, by St. Charles Borromeo (*q.v.*). A similar congregation of missionary priests, the Oblates of Mary Immaculate, have carried on extensive missionary activities in Canada. (*See* MARY IMMACULATE, OBLATES OF). Other congregations include the Oblates of the Virgin Mary (founded 1815), the Oblates of St. Francis de Sales (1871) and the Oblates of St. Joseph (1878). Of the congregations of women oblates, the best known is the Oblates of St. Frances of Rome (*see* FRANCES, SAINT). *See* also ORDERS AND CONGREGATIONS, RELIGIOUS. (C. J. BY.)

OBODRITES (BODRYCI, from *bodry*, "brave"), a people of the Polab group, the northwesternmost of the Slavs in medieval Europe. They inhabited the country between the lower Elbe river and the Baltic sea; *i.e.*, the country later divided between eastern Holstein (Wagria, so named from the Obodrite tribe of the Wagrowie, between the gulfs of Kiel and of Lübeck) and Mecklenburg. The Obodrites were allies of the Franks against the Saxons

in Charlemagne's time; but in 928 the Obodrite principality was conquered by the German king Henry I. The principality recovered its independence in 983 but was conquered again in the middle of the 12th century by Henry the Lion, duke of Saxony, after long resistance by the last pagan prince of the Obodrites, Niklot (d. 1160). Niklot's son Przybyslaw (Pribislav; d. 1178) accepted Christianity, acknowledged German suzerainty and was recognized in 1170 as a prince of the Holy Roman empire—to become the ancestor of the dukes of Mecklenburg (*q.v.*). First the dynasty and later the people became germanized.

See W. Bogusławski, *Dzieje Słowiańszczyzny północno-zachodniej,* 4 vol. (1887–1900). (K. Sm.)

OBOE, a treble woodwind instrument with a conical bore and double reed. It is used chiefly as a component of the orchestra but also has a considerable repertory of solo work.

History.—Even in its simplest form the conical pipe must be made by the skilful use of boring tools. No form of the instrument can be traced further back than about A.D. 300, nor is it indigenous among any primitive peoples in modern times.

Hautbois, or oboe, was one of the names applied to the shawm, the violently powerful instrument of outdoor ceremonial. But the oboe properly speaking (*i.e.,* the orchestral instrument) was the mid-17th-century invention of two French court musicians, Jean Hotteterre and Michel Philidor, and was designed to play indoors with the large bands of strings that were becoming common. This instrument, almost certainly softer and less brilliant in quality than the modern oboe, was probably first used in public in Lully's *Ballet de l'amour malade* (1657). Before the end of the 17th century it had become the principal wind instrument of the orchestra and military band and, next to the violin, the most important solo instrument of the time.

The early instrument, which had only two keys, could produce a fairly even chromatic scale by the use of "cross fingering" somewhat similar to that used by recorder players. The compass, at first two octaves upward from middle C, was soon extended, and solo works of the period of Mozart include the F above the treble staff. The instrument remained essentially the same well into the middle period of Beethoven.

(LEFT) 16TH-CENTURY SHAWM; (RIGHT) OBOE, ABOUT 1775, IN THE MACGILLIVRAY COLLECTION, LONDON

In the early years of the 19th century, however, the increasing complexity of music coincided with a number of improvements in the manufacture of keywork, particularly the introduction of metal pillars in place of the wooden ridges on which the keys had been mounted. This greatly reduced the threat to the airtightness of the instrument formerly associated with the introduction of additional keys, and in France, by 1839, the number of keys had been gradually increased to ten.

Meanwhile, before 1800, French players had adopted the narrow modern type of reed, and Guillaume Triébert (d. 1848) had begun his experiments, which, continued by his son Frédéric (d. 1878), were to result by the 1860s in an instrument almost identical with the modern oboe, both in bore and complexity of mechanism. This was essentially the expressive, flexible and specifically French instrument of the 20th century. The instrument in which the fingerholes are covered by perforated metal plates, now widely used in the U.S. and in France, was produced by François Lorée and Georges Gillet in 1906.

(LEFT) "GILLET MODEL" OR "SYSTÈME À PLÂTEAUX" OBOE, USED IN FRANCE AND THE U.S.; (RIGHT) MODERN AUSTRIAN OBOE

The centralized institutions of France probably helped to preserve the musical standards that made this evolution economically possible. (The working lives of the Triéberts roughly correspond to the greatest period of French grand opera; the new sensitive, lyrical oboe writing of Berlioz coincides with the early development of the new instrument; the gaiety, variety and agility in the scores of Delibes mark its completion.)

In other countries the decay of patronage and the public enthusiasm for military band music resulted in radically different traditions in oboe playing and manufacture. In Germany and Austria the rise of the many keyed instrument occurred earlier than in France and was accompanied by a development of the bore and reed that produced an increased loudness clearly of military inspiration. This resulted, after Beethoven, in a long period of neglect for the oboe. It is strange to consider that the dramatic solo in *Fidelio,* the high point of 19th-century German writing for the oboe, was almost certainly played on the baroque type of instrument with two keys. With the exception of the obbligato in Weber's *Der Freischütz* (1821), there is little after this in German scores that calls either for much sensitiveness or much technique until the end of the 19th century, when Richard Strauss campaigned successfully against the prevailing standards of playing. After a period of experiment with an extremely small reed, which was ill suited to the large German bore, the French oboe was fairly generally adopted by about 1925.

Comparable conditions in Italy produced a somewhat similar history. In modern times the German instrument (with a very small reed) survives in the U.S.S.R., where it is often played with a certain refinement, though it lacks the piquancy and sparkle of the modern French oboe. In Vienna an oboe similar to the German instrument, but with a rather more antique and less military character, is used exclusively by the Philharmonic orchestra and the Akademie. Its rather reticent and blending quality, which sounds well in the older classics, is caused, perhaps, more by the highly specialized type of reed used than by the inherent qualities of the instrument.

Elsewhere, orchestras use the French oboe exclusively, though often with slight local variations in the mechanism. An adaptation of the Boehm fingering to an otherwise normal French oboe is exported by Parisian makers to Spain and Latin America.

The Larger Oboes.—The cor anglais (*q.v.*), also known as the English horn, is pitched in F a fifth below the oboe and is a normal component of the modern orchestra, to which it was restored largely by the example of Berlioz and Wagner. It had been used intermittently, however, as a special effect ever since its earlier vogue in J. S. Bach's time, when the straight alto or tenor oboe of the 17th century made way for a curved instrument covered with leather and fitted with a globular bell. The origin of the name is unknown but it was to this form that the term cor anglais was specifically applied, and Bach's *oboe de caccia* was almost cer-

(LEFT TO RIGHT) OBOE D'AMORE, "GILLET MODEL," WITH AUTOMATIC KEYS; COR ANGLAIS WITH THUMB PLATE; GERMAN HECKELPHONE; MODERN FRENCH BARYTON

tainly the same instrument. The curved form survived late in Germany and was used in Italy until about 1900.

The *oboe d'amore* in A, a minor third below the oboe, is made with a globular bell like that of the cor anglais. Introduced in Germany about 1720, it was much employed by J. S. Bach. It was revived by Charles Mahillon in 1878 for Bach performances. It is also used in a few 20th-century works.

The instruments pitched an octave below the oboe are more rare. The baryton, both in its tonal quality and in its proportions, resembles a larger and therefore lower-voiced cor anglais. Despite several early examples, notably those by H. Brod and Triébert, its effective history dates from F. Lorée's model of 1889. The heckelphone (*q.v.*), with a much larger bore and reed than the baryton, has a more distinctive tone but is rather heavy in the low register. It was first used by Richard Strauss in *Elektra* and *Salome*.

The Reed.—The chief factor in playing the oboe is the making of the reed and its control by the lips and breath. Most serious players make their own reeds, though in modern times there is a considerable trade in the ready-made article. The raw material of the oboe reed is the plant *Arundo donax*, which resembles bamboo in appearance. It grows in warm temperate or subtropical regions, but only the crops of the *départements* of Var and Vaucluse in the south of France are satisfactory for reedmaking.

The dimensions of reeds, thickness of gouging, and length and shape of the scraped vibrating surface vary in different countries according to ideals of tone and the physical aptitudes of players.

The Repertory.—The revival of the oboe as a solo instrument that began, to some extent, in the 1930s accelerated very rapidly after the end of World War II and by the early 1960s there were probably more concerto players than at any time since the 18th century. Though a number of modern concertos were written for the instrument, the rich repertory of the early 18th century still remains the stock in trade of the oboe soloist.

OBRECHT (HOBRECHT), **JAKOB** (1452–1505), Netherlands composer, known chiefly for his sacred music, was born at Bergen op Zoom on Nov. 22, 1452. He was the son of Willem Obrecht, a trumpeter in the service of the duke of Cleves. Willem Obrecht had journeyed to Sicily and Mantua, and his musical contacts in Italy were ultimately to prove useful for his son. It has been suggested that the young Obrecht was trained at Ferrara, a city which he later visited when at the height of his fame. But his first certain appointment dates from 1484, when he served as instructor of the choirboys at Cambrai cathedral. In the following year he became succentor of the cathedral of St. Donatien at Bruges, but he soon applied for leave of absence to visit Italy. This was granted, and late in November 1487 he met Ercole I, duke of Ferrara, at the town of Goito in Lombardy. The duke had heard much of Obrecht's music and was one of his keenest admirers; once he had installed the composer in Ferrara he sought to prolong his stay by writing to Pope Innocent VIII and requesting that the next vacant benefice in Ferrara be given to Obrecht. The pope, however, did not grant this request; Obrecht returned north and by June 12, 1488, was in Bergen op Zoom. He resumed his duties in Bruges and was also nominated chaplain of the altar of St. Jodocus at Antwerp cathedral in 1498. He journeyed to Ferrara again in 1504 and in 1505 he died of the plague that ravaged the city and killed thousands of its residents.

Although Obrecht is best known for his liturgical music, he also wrote secular songs which include settings of Dutch, Italian and French texts. Twenty-five of these survive along with a number of motets, most of which are in honour of the Virgin Mary ("Salve regina," "Alma redemptoris mater," "Ave regina coelorum"). Twenty-seven settings of the Mass are extant, most of them for four voices. Obrecht's complete works were edited by Johannes Wolf (1912–21); other works were discovered later, and in the mid-1960s a new edition was being prepared by the Vereniging voor Nederlandse Muziekgeschiedenis. (D. W. St.)

OBREGÓN, ALVARO (1880–1928), Mexican soldier and president, was born near Alamos, Sonora, on Feb. 19, 1880. He had little formal education, and while a young man worked as a farmer and occasionally as a labourer in a small factory; in these two activities he developed a keen sense of reform. He did not take part in the revolution which overthrew the dictator Porfirio Díaz (1910–11), but in 1912 he led a group of volunteers in support of Pres. Francisco Madero against the rebels of Pascual Orozco. When Madero was overthrown and assassinated by the forces of Victoriano Huerta in Feb. 1913, Obregón joined with Venustiano Carranza against Huerta and consistently defeated the enemy armies. Huerta fled from Mexico in July 1914, and on Aug. 15 Obregón occupied Mexico City.

By Dec. 1914 differences among the victors brought new fighting. Obregón remained allied with Carranza against Pancho Villa and Emiliano Zapata; Obregón's military genius destroyed both opponents as serious threats within six months, although both remained as rebels for some years afterward. During the campaign against Villa, Obregón by decree instituted anticlerical policies and established maximum hours and minimum wages in the areas he conquered. At the convention which drafted the constitution of 1917, Obregón consistently gave strong support to the

more radical group, and to this extent was responsible for the revolutionary emphasis of that document. For a period in 1917 he served in Carranza's cabinet, but differences in ideology induced him to resign and for about two years he was politically inactive. He was a candidate for president in the election of 1920; in that year Carranza's attempt to retain power by having his own candidate elected brought about a rebellion in which Obregón played a leading role. Carranza was soon overthrown and on Dec. 1, 1920, Obregón was elected president.

As president, Obregón effectuated several of the constitutional provisions that Carranza had not enforced, and generally instituted widespread social and economic reforms. (*See* MEXICO: *Independent Mexico: Obregón and Calles.*) Because of his insistence on some of these reforms, the United States refused to recognize his government until 1923. Late that same year a rebellion began, led by Adolfo de la Huerta and supported by three-fifths of the army, but Obregón took the field and utterly defeated the rebels within four months; at no time in his career did he show more clearly his political and military brilliance. At the conclusion of his term he was succeeded as president by Plutarco Elías Calles.

Again a candidate for the presidency in 1928, Obregón was elected fraudulently after a bitter campaign in which his supporters assassinated a number of opponents. Shortly after his reelection, he returned from Sonora to Mexico City, where, on July 17, 1928, he attended a small victory celebration. While dining with his friends, he was shot and killed by José de León Toral, a fanatical Roman Catholic who held Obregón responsible for religious persecutions. (C. C. CU.)

OBRENOVICH (OBRENOVIC), the name of a dynasty which gave five rulers to Serbia in the 19th century. Whereas other European princes are generally numbered according to their Christian names, the Obrenovich princes are numbered according to their place in the dynastic succession. Milosh (*q.v.*) Obrenovich I was prince of Serbia from 1815 to 1839 and again from 1858 to 1860; his elder son Milan Obrenovich II (1819–39) was prince for 25 days in 1839; Milan's younger brother Michael (*q.v.*) Obrenovich III was prince from 1839 to 1842 and again from 1860 to 1868; Milan (*q.v.*) Obrenovich IV succeeded the childless Michael (his first cousin once removed) as prince in 1868 and was king of Serbia from 1882 until his abdication in 1889; and Alexander (*q.v.*) Obrenovich V was king in succession to his father Milan Obrenovich IV from 1889 until his assassination in 1903, when the dynasty became extinct.

O'BRIEN, one of the most common surnames in Ireland in the 20th century, is derived from Brian, the Christian name of the greatest medieval king of independent Ireland. He is usually known as Brian Boru (*Boroimhe*, "of the tribute"), who was killed at the moment of his great victory over the Northmen at Clontarf in 1014. He had been king of Thomond (northern Munster, comprising what is now County Clare with some adjacent territory) and his subsequent reign of 13 years as *Ard-ri* (high king of Ireland) was made illustrious by his military prowess, administrative developments and monastic foundations. It is incorrect to claim that the system of hereditary surnames was introduced by Brian Boru, but it is from his time that the general adoption of that form of nomenclature in Ireland dates. Since Ó (*Ua*) means grandson or descendant, he himself could not, of course, be styled O'Brien.

Before his time the Dalcassian clan known as *Uí Toirdealbhaigh*, to which his family belonged, was of comparatively minor importance. In the two centuries following his death the great sept of O'Brien divided into several branches throughout Munster, of which several of Brian's descendants were kings. The most important of these branches were the O'Briens of Ara in northern Tipperary, whose chief was known as Mac Uí Bhriain Ara; another branch settled by the Galtee mountains in the Aherlow district; a third moved farther east and acquired the fertile lands between the Comeragh mountains and Dungarvan in what is now County Waterford. These, and especially their original homeland, County Clare, are the counties in which the name is still most prevalent.

In the mid-18th century a branch of the family settled in France. A century earlier a branch had been established in the Netherlands, following the marriage of Daniel O'Brien with Susanna Jans, a Dutch lady, and became known as O'Breen. The O'Breens of Holland have thus no connection with the Irish sept of O'Breen (O'Braoin) of Brawney. The destruction of the old Gaelic order in the early 17th century and the transfer of legal work to English officials unacquainted with the Irish language resulted in some of them becoming almost unrecognizable in their new anglicized forms. Furthermore two surnames unconnected with O'Brien did to some extent assume that form. One of these was O'Breen (now seldom met with the prefix "O"), a natural mistake since O'Brien in Irish is pronounced as O'Breean. The infamous Jemmy O'Brien of 1798, for example, was an O'Breen, not an O'Brien. Similarly in some rare cases the Norman family of Bryan of County Kilkenny, when the period of Gaelic and Catholic submergence came to an end, assumed an "O" and became O'Brien. Conversely some O'Briens who had dropped the prefix wrote their name Bryan. Such cases, however, were never numerous. It may be added that the celebrated eight-feet-tall giant Patrick O'Brien, whose skeleton was acquired by the museum of the Royal College of Surgeons in London, only assumed the surname of O'Brien.

Sir Donough O'Brien, 16th Baron Inchiquin, chief of the name in 1962, is directly descended in the male line from Brian Boru. Until Tudor times Brian's successors remained virtually independent, though occasionally making minor concessions to the English as, for example, the cession by Brian Rua O'Brien of part of his territory between Limerick and Quin to Thomas de Clare who built the imposing castle of Bunratty, near the present Shannon airport. In that castle in 1272 De Clare murdered Brian Rua O'Brien in circumstances of great treachery and ferocity. Since the Anglo-Norman invasion the English kings had assumed the title of lord of Ireland, but in the 16th century, like the heads of the other great septs, the O'Brien of the time submitted to Henry VIII as king of Ireland. Murrough O'Brien (d. 1551), 57th prince of Thomond, had, like most of the other leading chiefs, been created a peer of the realm in compensation for the surrender of his Gaelic dignities: the titles conferred on him in 1543 were earl of Thomond and Baron Inchiquin. He also accepted the Reformation as part of the bargain and with certain exceptions his descendants remained loyal to the English king and the Protestant religion.

A notable feature of the original creation is that the succession to the earldom of Thomond was to pass to Murrough's nephew Donough, his son Dermod inheriting only the barony of Inchiquin. Other subsequent peerages given to the O'Briens became extinct and only the lesser of the original titles survives. This accounts for the present holder being Baron Inchiquin, not earl or marquess of Thomond or earl of Inchiquin. Conor O'Brien (*c.* 1535–81), 3rd earl of Thomond, was at war with the English for a while, but after his defeat and flight to France in 1570 he was pardoned. His son Donough (d. 1624), 4th earl, was active on behalf of Elizabeth I and under James I became president of Munster. The earldom became extinct after the death of Henry (1688–1741), 8th earl, who was created Viscount Tadcaster.

The Inchiquin line was also identified with the English interest, particularly in the 17th century, when the ruthless activities of Murrough O'Brien (*c.* 1614–74), 6th baron and 1st earl of Inchiquin, on behalf of Oliver Cromwell during the war of 1641–52 earned him the nickname of Murrough of the Burnings. He later espoused the royalist cause and did much to assist in bringing about the Restoration. His son William (*c.* 1640–92), 2nd earl, served under his father in France and Spain and spent some years as governor of Tangier. At the revolution in 1688 he took the side of William III, who made him governor of Jamaica, where he died in 1692. Murrough (1726–1808), 5th earl, was created marquess of Thomond in 1800, but on the death of his second son in 1855 the marquessate became extinct.

A very different picture is presented by the line descended from Daniel O'Brien (1577–1666), younger brother of Connor, 3rd earl of Thomond. Daniel was created Viscount Clare by Charles II, whom he joined before the Restoration; he had been prominent in the Irish parliament and subsequently a member of the supreme council of the Catholic confederation of Kilkenny. His grandson

Daniel (d. 1691), 3rd viscount, who had been lord lieutenant of County Clare under James II, was outlawed in 1691 and raised the regiment of James's Irish army, later to become famous as Clare's dragoons in the Irish brigade on the continent under the command of his son Charles O'Brien, nominally 5th viscount, who was mortally wounded at the battle of Ramillies (1706). His son Charles O'Brien (1699–1761), titular 6th viscount, commanded the Irish brigade at the battle of Fontenoy and was made a marshal of France in 1741. His claim to the earldom of Thomond, disallowed by the English authorities because of the attainder, was recognized by the French court. With the death of his son Charles in 1774 these titles became extinct.

In addition to the 6 O'Briens who served as officers in Clare's dragoons, there were over 20 O'Briens commissioned in other regiments of James II's Irish army; and 24 appear in the list of outlawries which followed the defeat of the Jacobite cause. Later they were equally prominent in the Irish brigade on the continent.

Others of the name have also distinguished themselves in various spheres of activity. In politics, besides Sir Lucius O'Brien (d. 1795), member of parliament and advocate of Irish independence, and William Smith O'Brien (1803–64), member of parliament and Young Irelander, there were William O'Brien (1852–1928), Parnellite and later independent member of parliament, and another William O'Brien (1881–), labour leader and comrade of James Connolly. Some politicians might better be included in the category of adventure and war, for example James Francis Xavier O'Brien (1828–1905), member of parliament, who took part in the Fenian rising of 1867 and the American Civil War, and Fitzjames O'Brien (1828–62), who was killed in that war. In the American Revolutionary War, Jeremiah O'Brien (1740–1818) and his two brothers John and William were renowned for their naval exploits on the American side; Adm. Donat Henchy O'Brien (1785–1857), on the other hand, served the British empire with distinction. A victim of war, though not an active participant, was Terence Albert O'Brien (1600–51), Dominican bishop of Emly, who was hanged by Gen. Henry Ireton after the siege of Limerick. Well-known names in literature and science are Matthew O'Brien (1814–55), mathematician and astronomer; Paul O'Brien (1763–1820) of Maynooth, and John O'Brien (d. 1767), bishop of Cloyne and Ross, who were Gaelic scholars; Richard Barry O'Brien (1809–85), historian, and Charlotte Grace O'Brien (1845–1909), poetess, novelist and philanthropist. The extent to which less known people of the name have contributed to the corpus of Irish literature is indicated by the fact that there are about 100 O'Briens in the Royal Irish Academy catalogue of Gaelic manuscripts. There are approximately 300 O'Briens mentioned in the *Annals of the Four Masters* from the date of the adoption of the name in the 11th century down to 1616, when that chronicle ends. Similarly in the *Annals of Innisfallen*, which deals principally with the southern half of Ireland, the name O'Brien appears more frequently than any other.

Another aspect is the connexion of place-names with families; thus in the case of O'Brien, there are Pubblebrien, one of the baronies of County Limerick, and O'Brien's Bridge, the village on the river Shannon where the ancient bridge joins the counties of Clare and Limerick.

See E. MacLysaght, *Irish Families* (1957), and *More Irish Families* (1960), which include bibliographies. (E. A. MacL.)

O'BRIEN, JAMES BRONTERRE (1805–1864), British radical, sometimes known as the "Chartist schoolmaster," was one of the few Chartists with a well-articulated theory of society and government and a realistic sense of tactics. Born at Granard, County Longford, in 1805, he was educated at Trinity college, Dublin, and moved to London in 1829, intending to practise at the English bar. He was quickly drawn into radical activities and later into working-class journalism. In 1831 he was acting editor of the *Poor Man's Guardian*, the unstamped organ of extreme radical views. After a short time in Birmingham at the height of the Reform bill crisis, he returned to London and his old newspaper. When the *Guardian* expired in 1835, he took up other journalistic assignments. He was a keen and searching writer who took pains to acquaint himself with the history and organization of revolutionary movements in Europe as well as with working-class politics at home. Bitterly opposed to his compatriot Daniel O'Connell, he naturally threw in his lot with Feargus O'Connor in the early days of the Chartist movement and from 1838 to 1840 he worked on O'Connor's *Northern Star*. He was one of the most important and influential Chartists at the convention in 1839, where he advocated "ulterior measures" to secure the Charter should constitutional means fail. However, he was sentenced to 18 months' imprisonment in 1840, and while in jail he had the first of a number of quarrels with O'Connor which transformed his political prospects. The two men were bitter enemies by 1844. O'Connor's land plan had no more scathing critic, and at the Chartist convention of 1848 O'Brien took up a moderate position, ridiculing the possibility of being able to use force effectively. In 1850 he was a joint founder of the National Reform league, which advocated socialist objectives. In his last years, spent in considerable hardship, he wrote political poetry. He died on Dec. 23, 1864. (A. Bri.)

O'BRIEN, WILLIAM (1852–1928), Irish patriot, a founder of the United Irish league, was born at Mallow, County Cork, on Oct. 2, 1852, the son of James O'Brien, a solicitor's clerk. He was educated at the Cloyne diocesan college and at Queen's college, Cork, and took up journalism in 1869. In 1881 he became editor of *United Ireland*, which he conducted with such vigour from August to October that it was suppressed for the time being, and O'Brien was put in Kilmainham jail with Charles Parnell and others. There he drew up the famous "No Rent manifesto," which led to the Land league's being outlawed.

Released in 1882, O'Brien resumed his campaign in *United Ireland* and was elected to parliament for Mallow in 1883. In 1886, O'Brien started the slogan of "no reduction, no rent." Parnell was out of Ireland at the time and eventually disavowed the plan, but O'Brien had stirred up a fierce agitation. To meet the situation the British government passed the Coercion act of 1887, under which O'Brien was sent to Tullamore jail. On his release he appeared in the house of commons to renew his obstructive tactics there.

After the O'Shea divorce case, in which Parnell was involved, O'Brien tried to mediate between the Parnellites and the anti-Parnellites, siding with the majority who rejected Parnell's claim to retain leadership. In 1900, after years of bitter strife, both sections were reunited under the Parnellite John Redmond, largely as a result of O'Brien's formation of the United Irish league in 1888. Having given active support to the Land conference, which secured agreement between the landlords and tenants' representatives and resulted in the Wyndham Land Purchase act of 1903, O'Brien became convinced that nationalists and unionists could unite for common purposes. He founded the All-for-Ireland league, which obtained a large following in County Cork, in opposition to Redmond's control of the United Irish league. But O'Brien's personal following did not survive the rise of the Sinn Fein agitation, and after World War I (Irish participation in which he had supported) he withdrew from public life. He died in London on Feb. 25, 1928.

O'BRIEN, WILLIAM SMITH (1803–1864), Irish patriot, leader of the Young Ireland movement, was born at Dromoland, in County Clare, on Oct. 17, 1803, and educated at Harrow and at Trinity college, Cambridge. He began to use his second name of Smith on inheriting his maternal grandfather's estates in Limerick. He entered parliament in 1828 as member for Ennis and from 1835 to 1848 represented the county of Limerick. Although he actively supported Catholic emancipation he opposed Daniel O'Connell's election for County Clare in 1828 and continued to oppose repeal of the legislative union until O'Connell's imprisonment at the end of 1843. O'Brien then joined the Repeal association and was at once appointed deputy leader while O'Connell was in prison. He became closely associated with Thomas Davis and Gavan Duffy and the brilliant group who later became the Young Ireland party; and in 1846 he led them in withdrawing from the Repeal association, when O'Connell demanded repudiation of any conceivable resort to arms. Early in 1847 they formed the Irish confederation to press for a more active policy during the years of famine. In May 1848, after a mission to Paris to congratulate the new French

republic, O'Brien was tried for sedition, but was acquitted. He exercised a restraining influence until the government issued warrants to arrest all the most active leaders. O'Brien then assembled them to make a last stand and appealed for a general rising. It collapsed in a short collision with the police and military forces at Ballingarry. O'Brien was arrested at Thurles, tried for high treason and condemned to death. The sentence was, however, commuted to exile to Tasmania for life. O'Brien obtained a full pardon in May 1856 and returned to Ireland. He died at Bangor, north Wales, on June 18, 1864.

O'BRYAN, WILLIAM (1778–1868), was the founder of the Bible Christian Church, an offshoot of Wesleyan Methodism which was confined almost entirely to southwestern England. He was born at Gunwen, Cornwall, on Feb. 6, 1778. He was for a time a successful Wesleyan local preacher, but his independent behaviour led to his expulsion in 1815. In 1815 he formed the first Bible Christian society at Shebbear in north Devon. By 1824 there were 6,200 members. After increasing friction between him and his followers, O'Bryan in 1829 withdrew altogether from the Bible Christians; only a small party seceded with him and they returned in 1835. He left England in 1831 and worked extensively as an itinerant revivalist in the United States and Canada. Though he revisited England frequently, he did not become reconciled to the Bible Christians there. He died in New York on Jan. 8, 1868.

The Bible Christians held doctrines common to the rest of Methodism, their organization being controlled by an annual conference after 1819. In 1907 they joined the United Methodist Church. *See* METHODISM.

(J. H. S. K.)

OBSCENITY, in general, refers to conduct offensive to the public sense of decency. From the point of view of the law, it is essentially concerned with the publication of indecent matter. In England until the 18th century it was regarded as a matter for the ecclesiastical courts, but in 1727 there was a successful prosecution for this offense in a temporal court, and thereafter it became recognized as an indictable misdemeanour at common law. In 1857 it was dealt with for the first time by statute in the Obscene Publications act of that year, now repealed (for England but not Northern Ireland) by the Obscene Publications act, 1959. (Neither statute has effect in Scotland.) In the United States, all of the states have laws regulating the dissemination of obscene materials, and more than 50 nations are parties to an international agreement for its control. The basic legal control has been through the criminal law, but the United States and most other countries also provide for administrative regulation by the customs, by the postal service and by state or local boards for the licensing of movie or stage performances. Possession of obscene materials without intent to sell is not a crime.

The principal target of the law has been commercialized pornography. However, control of obscenity necessarily entails control of discussions and portrayals of sex, lust and love, and it is, therefore, no surprise that the law has frequently provided celebrated controversies over government censorship of art and letters.

In 1957 the United States supreme court in *United States* v. *Roth* put to rest lingering doubts about any inconsistency between the law of obscenity and U.S. constitutional doctrines regarding freedom of speech and expression. The court also restated the basic U.S. definition of obscenity: "Whether to the average person, applying community standards, the dominant theme of the material taken as a whole appeals to prurient interests." This restatement, which seemed likely to become the formula for future U.S. cases, summarizes an important change in the law. The first great English precedent in *Regina* v. *Hicklin* in 1868 has been understood to mean that the test was the effect of isolated passages on the particularly susceptible. Not only does the *Roth* case make it unquestionable that the relevant audience is the average reasonable adult (unlike the test formulated by the English Obscene Publications act of 1959) and that the work must be considered as a whole (as in English law) but it strongly intimates that any more restrictive test would violate the U.S. constitution.

Two other points of importance have been clarified in decisions of the supreme court. First, obscenity no longer covers "thematic" obscenity in which immoral or unconventional ideas of sexual behaviour are sponsored. In 1959 the court held that New York city could not ban a movie simply because it "approvingly displays an adulterous relationship." Second, the court has indicated it will be difficult to create new crimes on analogy to obscenity; in 1947 it struck down as unconstitutional the attempt of New York to make it a crime to publish "massed" stories of crime and bloodshed.

Among troublesome issues that still remain are the constitutionality of motion-picture and postal regulations of obscenity, which have been challenged as prior censorship schemes; the status of the bookseller, who is frequently prosecuted although he may have little knowledge of or interest in the particular item; and the special problems of portrayals of "obscene violence" aimed at the young in the form of comic books.

Around the early 1920s the U.S. jurist Learned Hand spoke of obscenity as "the critical point" between candour and shame reached at any moment in a society. That remains an apt assessment both of the need for and the perplexity of the contemporary law of obscenity. *See* also CENSORSHIP: *Obscene Literature.*

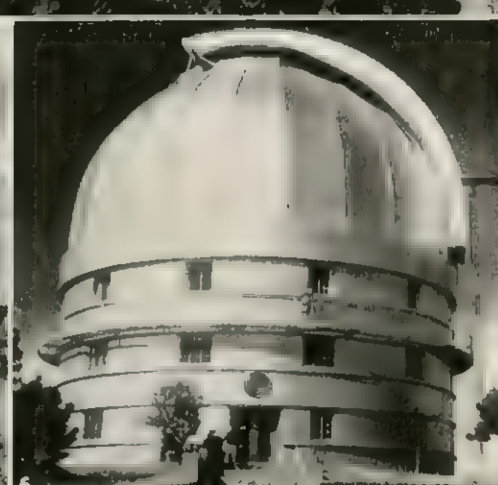
OBSERVATORY (ASTRONOMICAL). This article covers the important observatories of the world. For a general discussion of the purpose and work of astronomical observatories and for the history and technical aspects of the telescope, *see* ASTRONOMY and TELESCOPE.

The erection of special buildings for astronomical research is a practice of long standing. It is said by Diodorus that the great temple of Belus at Babylon was built for astronomical purposes, and, since there is indication in the Chinese records that the gnomon was used for measuring the height of the sun in the reign of the emperor Yao (2300 B.C.), it may be said that the beginning of practical astronomy was contemporaneous in eastern and western Asia.

There is no evidence of the existence of an observatory of Greek or Alexandrine origin until the time of Ptolemy Soter, who, about 300 B.C., built one at Alexandria. The earliest records from an observatory known to be extant are those of Hipparchus (c. 140 B.C.), who has left a catalogue of stars from observations made at the island of Rhodes, repeating those made earlier at Alexandria. Three hundred years later, Ptolemy (A.D. 150) compiled a star catalogue, but it is doubtful whether this was from his own observation and, therefore, whether he had an observatory other than that at Alexandria.

The art of astronomical observation was revived several hundred years later in western Asia when observatories were established at Damascus and Baghdad and one at Mokatta by Caliph Hakim about A.D. 1000. A splendid observatory was built at Maragheh in northwest Persia by Hulagu Khan about A.D. 1260, but the most productive was that of the Persian prince Ulugh Beg, grandson of the great Timur, who, at Samarkand with his assistants, made a catalogue of stars from observations with a large quadrant in the first half of the 15th century. Later in that century, about 1471, Johann Müller of Königsberg, better known as Regiomontanus, set up an observatory at Nürnberg, with the help of Bernhard Walther of that city, furnished with instruments of his own design, and after his death in 1476, clocks, then a recent invention, were added to the equipment. The first observatory, however, that may be considered a prototype of modern national observatories was that of Tycho Brahe on the island of Hven (Ven), off the southwest coast of Sweden. To the building commenced on Aug. 8, 1576, he gave the appropriate name Uraniborg ("castle of the heavens").



BY COURTESY OF (1) LICK OBSERVATORY, (2) EDISON R. HOGE, (3) THE DIRECTOR, MC MATH-HULBERT OBSERVATORY, (4) FAIRCHILD AERIAL SURVEYS, (5) YERKES OBSERVATORY, (6) ELWOOD M. PAYNE

AMERICAN OBSERVATORIES

1. The Lick observatory on Mt. Hamilton, Calif., completed in 1887–88. The domes on main buildings covering the 36-in. and 12-in. refractors are shown
2. The dome of the 200-in. Hale reflecting telescope, at Mt. Palomar, California
3. The McMath-Hulbert observatory of the University of Michigan, located near Pontiac, Mich., and devoted to solar work. The smallest dome houses a 24-in. reflecting telescope. The middle tower contains a coelostat and the tower-type solar telescope with a 30-ft. spectrograph. The highest tower also houses a coelostat and tower-type solar telescope with vacuum spectrograph
4. Mt. Wilson observatory, near Pasadena, Calif., established in 1904–05. Its largest reflecting telescope, completed in 1917, has a mirror 100 in. in diameter
5. Yerkes observatory of the University of Chicago, at Williams Bay, Wis., completed in 1897. View from the southwest
6. The W. J. McDonald observatory. Dome of the 82-in. reflecting telescope of Mt. Locke, Texas. Founded in 1939 jointly by the University of Texas and The University of Chicago

OBSERVATORIES OVER THE WORLD

1. Dome of the 48-in. reflecting telescope of the Astrophysical observatory near St. Michel, 60 mi. northeast of Marseille, France
2. Royal observatory, Edinburgh, Scotland. On Blackford hill. Established in 1896 in place of an observatory on Calton hill, Edinburgh
3. Office building of the Astrophysical observatory near St. Michel, France
4. General view of the historic building of the Pulkowa observatory [illegible] the U.S.S.R., destroyed during the siege of Leningrad in World War II. The Russian government reconstructed the building on the original plans with instruments of modern type
5. General view of the La Plata observatory at La Plata, Argentina

Tycho Brahe's Observatory.—This building was of some magnitude and large enough to house Tycho and several young men who lived with him as students or observers. It was furnished with a large quadrant attached to a wall in the plane of the meridian, for to this astronomer is due the credit of appreciating the advantage of size in instruments of this type, and of the principle which is embodied in the mural circle. There Tycho Brahe with his assistants, one of whom was Longomontanus, a name well known in the science, observed the heavens and produced a catalogue of the positions of more than 1,000 stars. On the death of his patron, Frederick II, in 1588, Tycho was deprived of royal favour and income. In 1597 Tycho left Denmark, the observatory at Hven having been already dismantled.

The invention of the telescope in 1608 opened a new chapter in the history of observatories, and the building at Padua in which Galileo discovered and made the first observations of Jupiter's satellites on Jan. 7, 1610, may be regarded as the first of a new class. Others were created as additions to universities or similar institutions during the 17th century. In 1637, King Christian IV of Denmark established a permanent observatory at Copenhagen, which was completed 20 years later.

Johannes Hevelius, a member of a noble family of Danzig, built an observatory in 1641 in his own house and furnished it with an azimuthal quadrant of five-foot radius and a sextant of six feet, with which he measured the meridian altitudes of stars, sun, moon and planets, and their distances from one another in the manner of Tycho—that is, with plain sights, believing this to be superior to the newly adopted telescopic method.

Paris, Greenwich and Others.—Hevelius died early in 1687 and his work was not carried on, but by that date there had come into existence the two national observatories at Paris and Greenwich. The former was built in the years 1667–71, according to the designs of Claude Perrault, as an architectural monument. Under the Cassinis and others it has done much for astronomy. The Royal observatory, Greenwich, was founded in 1675 for the definite purpose of the improvement of navigation. Architectural pride again entered into the design, for Sir Christopher Wren wrote of it to Bishop Fell of Christ Church, Oxford, as built "a little for pomp," referring to the main building. The essential instruments were housed apart, and Wren's beautiful creation is merely a small item in its extensive domain.

Few establishments of the kind were erected during the next half century. Mainly because of the occurrence of the transit of Venus in 1769, George III built and furnished the King's observatory at Kew. The improvement in reflecting telescopes by James Short and the invention of the achromatic object glass in the later part of the 18th century marked the beginning of many observatories that have since become famous. The Radcliffe observatory at Oxford was erected 1771–74 from funds bequeathed by John Radcliffe, a court physician "for charitable purposes," the words being interpreted somewhat widely. Provost Andrews bequeathed a substantial sum for building and endowing an astronomical observatory for the University of Dublin which was built at Dunsink in 1785 but not furnished with instruments until many years later. An observatory was established and endowed at Armagh in Ulster in 1791 in charge of Primate Richard Robinson, while the most productive British observatory of the period was that of William Herschel at Bath, Datchet and Slough successively.

Early Continental Observatories.—Continental observatories established during this period were those of Mannheim (1772?), which was transferred to Karlsruhe in 1880, and again to Heidelberg in 1896; Lilienthal, founded by J. H. Schroter in [illegible] and furnished with a reflector made by Herschel; Leipzig, where a small observatory existed on the tower of the university in the years 1787–90; Breslau (1790); also one at Seeberg near Gotha founded by Duke Ernest II in 1788 that was made famous by F. X. von Zach and J. F. Encke. The observatory at Palermo, where G. Piazzi made his famous catalogue of stars, was founded in 1790, and at about the same time J. Lalande and his assistants were observing transits of stars from an observatory in the École Militaire, Paris.

19TH CENTURY

British Observatories.—A full list of observatories, public and private, founded in Great Britain during the next 100 years would be large. An observatory on Calton hill, founded by a private association, the Edinburgh Astronomical institution, in 1818, was taken over by the crown as a royal observatory in 1834 and transferred to its present site on Blackford hill in the years 1889–96. Cambridge university observatory was founded in 1820 and under its noted directors, George Biddell Airy, James Challis, John Couch Adams, Robert Stawell Ball and Arthur Stanley Eddington, has done valuable work; by the end of the century it was well equipped with instruments for solar and astrophysical observations. The Radcliffe observatory at Oxford was originally in the charge of the Savilian professor of astronomy, but this arrangement lapsed and the offices of professor and Radcliffe observer became distinct about 1839. In 1875 the University observatory came into existence, largely through the liberality of Warren de la Rue, for the use of the Savilian professor. The work of this observatory has been primarily photographic. An observatory was established at Liverpool mainly for the time service of the port in 1838, and at Glasgow a small observatory attached to the university, of which Alexander Wilson had been the first director about 1760, was enlarged and transferred to a new site in 1836.

Among private observatories the reflecting telescope, with a six-foot mirror made by Lord Rosse and set up at his seat, Parsonstown, Ire., in 1845, is famous, and scarcely less so are the smaller instruments of the same type made by William Lassell, and used by him at Liverpool 1844–52.

Observatories established in England in the second half of the 19th century were those of De la Rue, a pioneer in astronomical photography, at Cranford in Middlesex; of George Knott at Cuckfield, Sussex; and of William Huggins, the famous spectroscopist, at Tulse hill; the private observatory of Norman Lockyer, who afterward developed spectroscopic research at a state-supported establishment at South Kensington. Those of Edward Crossley at Halifax, Yorkshire, and Thomas Espin at Towlaw, Durham, have reputations based on double-star observations.

Colonial Observatories.—A feature of the 19th century was the establishment of British colonial observatories. Acting on the proposal of the board of longitude in 1820, the lord commissioners of the admiralty resolved to establish an observatory at the Cape of Good Hope for the improvement of practical astronomy. It came into being in the year 1829, and fulfilled its purpose as a government observatory under the directorship of Thomas Maclear, Edward James Stone, David Gill, George Washington Hough, Harold Spencer Jones, John Jackson and R. H. Stoy (from 1950). This observatory has a reversible transit of modern type and an equatorial twin telescope with a 24-in. photographic lens and 18-in. visual lens, known as the Victoria telescope for photographic and spectroscopic work. In 1834 Sir John Herschel established at the Cape a temporary observatory which is historically important. During four years he completed a survey of the southern heavens, extending the work his father had done many years earlier on the northern sky.

The first observatory on Australian soil was one on Dawes point, on the headland of which stands the present Sydney observatory, established in 1786. In 1853 Robert L. Ellery was appointed to superintend an astronomical observatory at Williamstown which was moved to Melbourne in 1861–63. With the observatories of Sydney and Perth, Melbourne has taken a share in the international work of charting the heavens by photography, and in addition meridian observing, magnetism, seismology, meteorology and time service form its activities. The Adelaide observatory was not completed until 1861. The observatory of Western Australia at Perth was established 30 years later. The aim of a small observatory established at Wellington, N.Z., under Sir James Hector, in 1869 for time service was later enlarged and the institution named the Dominion observatory.

Continental Observatories.—During this period many observatories were established on the continent of Europe, two of which were made famous by the labours of Wilhelm Struve. The

University at Dorpat, Livonia, Russia, possessed in 1820 an observatory of small dimensions, scantily equipped, of which Struve, a member of the faculty of the university, was given charge in 1813. His successful work attracted the attention of the Russian government, and soon the observatory was furnished with such instruments and pecuniary means as to raise it to the rank of a first class establishment, where Struve, almost single-handed, produced results of a very high standard. Attracted by Struve's work, the emperor Nicholas in 1834 resolved to erect a central observatory for the empire of Russia, and largely to Struve's design an observatory was completed in 1839 at Pulkovo near St. Petersburg, which was considered to be the finest and best equipped of the time. Another observatory of the first half of the 19th century, though not on the magnificent scale of Pulkovo, but associated with the name of a distinguished astronomer, was that of Königsberg, established by the king of Prussia in 1813 and put in the charge of F. W. Bessel, who had already made a reputation at the observatory at Lilienthal. The observatory at Altona near Hamburg, completed in 1823, was made famous because of its association with Heinrich Christian Schumacher, to whom is ascribed the encouragement given to astronomy by the Danish government. In 1874 this observatory was transferred to Kiel, which had then become the chief German naval station, and formed the international central bureau for distribution of astronomical information until World War I, when this useful work was transferred to Copenhagen.

The Royal observatory at Berlin had its origin in the year 1705. It was with the nine-inch refractor of this observatory that the planet Neptune was first seen. The establishment of an observatory at the University of Bonn was decided on by the king of Prussia in 1836, and Friedrich Wilhelm Argelander, who had been director of the Abo observatory, Finland, transferred to Helsingfors in 1832, was chosen as director. Although the instruments of this observatory were not large, stupendous work in star cataloguing, its principal branch of activity, was carried out by Argelander and his successors. The University of Strasbourg has an observatory attached to it, completed by the German government in 1881, consisting of three magnificent buildings placed in a large open garden. Its largest telescope, the great equatorial, a refractor with object glass of 20-in. aperture, is said to have been the largest in Germany at the time of its erection. The University observatory, Vienna, built on a new site in the years 1874–80 to replace one that dated from the middle of the 18th century, is a large structure standing in grounds of 14 ac. in extent, with an imposing façade and surmounted by four domes designed on the model of the Berlin observatory. Basel (1874), Bordeaux (1880), Breslau (1790), Budapest (1806), Cracow (1791), Kazan and Leipzig (1790, remodeled in 1861) are other universities of Europe that have observatories attached to them. At Heidelberg (Königstuhl), a private observatory founded by Max Wolf in 1877 was merged with Grand Ducal institute established in 1898, which combined two sections—one an astrometric observatory that had existed previously at Schwetzingen, Mannheim and Karlsruhe since 1764, and an astrophysical observatory under the direction of Wolf.

Among the notable observatories in northern Europe established before 1800 but greatly expanded in later years is the Stockholm observatory, founded in 1748. It is equipped with a large double equatorial telescope, a 40-in. reflecting telescope and many modern auxiliary instruments. Also notable are the observatory of the University of Uppsala, founded in 1730, the Royal observatory of Lund, first established in 1750, and the University observatory of Copenhagen, originally built about 1640 on the summit of the famous "round tower."

Before World War I there were ten French national observatories under the control of a consultative committee that reported annually to the government. The Paris observatory of the 17th century has been mentioned. Some that were resuscitated or created in the ten years after the war of 1870–71 have interesting histories. An observatory at Marseilles, founded by the order of Jesuits in 1702, was taken over in 1763, after the expulsion of the order, as the Royal Naval observatory and was made famous by Jean Louis Pons, Joseph Bernard, Adolphe Gambart [illegible] and Jean Chacornac. A new observatory was [illegible] which the older one was incorporated, and the names Stephen Jerome Coggia and Alphonse Louis N[illegible] recall many discoveries of minor planets and comets [illegible] instruments. The observatory at Toulouse had a [illegible] early as 1718, but the existing establishment dates from [illegible] when it was erected and supplied with excellent instruments at public expense, but with an inadequate staff, so that it was [illegible] for many years solely to meteors and meteorology.

The observatory at Bordeaux, together with those at Toulouse and Algiers, has taken a share in the international work of charting the heavens by photography. The Algiers [illegible] is an imposing group of buildings set up on a [illegible] near Algiers. The observatory at Nice was bequeathed by its founder to the University of Paris in 18[illegible], and later became a national institution. Other observatories were located at [illegible]souris, Besançon and Lyons. The last of ten is [illegible] observatory at Meudon near Versailles. For many [illegible] been pre-eminent in solar physics. It also has the largest [illegible]ing telescope in Europe, of 33-in. aperture, which was [illegible]sively for study of the planet Mars.

U.S. Observatories.—The first U.S. observatory is [illegible] been erected at the University of North Carolina [illegible] in 1831–32. It was destroyed by fire in 18[illegible]. [illegible] servatories were started at Williams college, Williamstown, [illegible] in 1836, at Hudson, O., 1836–37, and [illegible] the Nat[illegible] at Washington, D.C., which was actually established [illegible] J. M. Gilliss of the U.S. navy in 1843–44. The [illegible] encouraged and in many cases observatories were [illegible] lective financial help. By the efforts of O. M. Mitchel [illegible] raised for shares in a public company to build [illegible] Cincinnati, O. The first meeting of stockholders [illegible] May 23, 1842, and an object glass 11 in. in diameter [illegible] quite large for that epoch, was procured [illegible] Litchfield observatory of Hamilton college, Clinton, N.[illegible] founded by public subscription in 18[illegible]. An observatory [illegible] to the University of Missouri, Columbia, in 185[illegible] improved by a gift from S. S. Laws. In 1856 the Dudley [illegible]tory, Union college, Albany, N.Y., was established [illegible] local citizens and was named for the largest donor, Mrs. [illegible] Dudley. The Allegheny observatory of the University [illegible]burgh, Pa., founded in 1860, was completed [illegible] the liberality of W. Shand. The Dearborn observatory [illegible] University of Chicago was built in 1863, but was [illegible] western university, Evanston, Ill., in 1887. The [illegible]servatory attached to Princeton university [illegible] in 1866. The Leander McCormick observatory of the [illegible] of Virginia, Charlottesville (1885), the Washburn [illegible] the University of Wisconsin, Madison (1878), the [illegible] Michigan observatory, Ann Arbor (1854), and [illegible] observatories are used both for purposes of education [illegible] astronomical research.

The U.S. Naval observatory at Washington, D.C., is [illegible] akin to Greenwich, since it is a [illegible] for the purposes of the navy. Chronometers are [illegible] tested, and the staple astronomical work has been [illegible] star catalogues and astronomical calculations.

One of the most famous of the observatories [illegible] was that of Harvard college, the origin [illegible] Cranch Bond, a member of a Cornish family [illegible] 1786 and settled in Portland, Me., where he was [illegible] Bond had great aptitude for scientific research [illegible]omy, and when, in 1837, it was decided to [illegible] for Harvard, he, though engaged in a profitable [illegible] business, accepted the invitation to take charge [illegible] attached to the office until 1846. The original Harvard [illegible]tory (Dana house, 1839), and the new observatory [illegible] established by public subscription. Under the dir[illegible] Pickering, the work of this observatory was [illegible] and spectroscopic. Harvard had no telescope [illegible] new observatory was furnished with a 15-in. equatorial

of the two largest made up to then. Later a photographic [illegible] of 24-in. aperture was added, the gift of Miss Catherine [illegible]. Harvard had a branch observatory in Arequipa, Peru, at [illegible] tion in the Andes, built and largely supported by a sum [illegible] for the purpose by Uriah Boyden, but this was in 1928 transferred to South Africa.

Yale university has an observatory, founded in 1882, which is [illegible] for its work on the determination of stellar parallaxes and [illegible] astronomy. The private observatory of Percival Lowell of Flagstaff, Ariz., has attracted attention because of the [illegible] ons of the surfaces of the planets made there, for which it was founded in 1894. The outermost planet, Pluto, was discovered there in 1930.

In South America, there had been an observatory at Buenos Aires, Arg., in 1822, whose period of activity was short, so that the National observatory at Santiago, Chile, may be regarded as the first permanently founded (1856) on the continent. The National observatory of the Argentine republic, established at Córdoba, [illegible] did good service in cataloguing the stars of the [illegible] hemisphere. It acquired a 60-in. reflecting telescope. The other major South American observatory, also in Argentina, was founded at La Plata in 1882.

The last quarter of the 19th century may be said to have seen the beginning of the era of the large telescope, though the large [illegible] of Parsonstown (6 ft.) and Melbourne (4 ft.) were earlier. [illegible] refractor at Washington, D.C., dates from [illegible], but [illegible] years later a telescope was made on a considerably larger [illegible] through the beneficence of James Lick. The telescope, with [illegible] 36 in. in diameter, is set up in an observatory on [illegible] Hamilton, Calif. In 1895 a reflector with a silver-on-glass [illegible] diameter that had been used by A. A. Common [illegible] by Edward Crossley of Halifax, Eng., and with these instruments and others, the Lick observatory, attached to the [illegible] of California, Berkeley, has done much photographic [illegible] observation. The size of the larger instrument [illegible] years later when, in Oct. [illegible], through the [illegible] George Ellery Hale, C. T. Yerkes presented a refracting [illegible] object glass of 40-in. aperture, together with a large [illegible] building containing it on the shore of Lake Geneva [illegible] The University of Chicago. From that date the Yerkes [illegible] has been pre-eminent in spectroscopy and astro[illegible] and has contributed much to our knowledge of double [illegible] satellites and comets.

20TH CENTURY

Modern Observatories.—The names and locations of active [illegible] observatories are printed yearly in the *American [illegible] and Nautical Almanac*. The progress of astronomy [illegible] changes in the aim of celestial research, have brought [illegible] in the characteristics of observatories. At the beginning [illegible] century the equipment of an observatory may be said [illegible] consisted of a meridian instrument with an equatorial as [illegible]; in the latter half of the 20th century the latter was the more important instrument, usually supplemented by [illegible] equipment, spectrographs and other instruments. [illegible] determination of the positions of [illegible], the [illegible], however, continues as standard work at Greenwich, Washington, D.C., and other national observatories, since [illegible] are necessary for the maintenance of fundamental [illegible]

[illegible] trends of the 20th century have been the making of [illegible], in some cases of [illegible] for special re[illegible] and the establishment of branches [illegible] [illegible] considered more suitable [illegible] than [illegible]. One important example is the observatory [illegible] 1904–05 on Mt. Wilson, 5,700 ft. above sea level, near [illegible] Calif. This observatory was established by George [illegible] as a department of the Carnegie institution of Washington. The telescopes are on Mt. Wilson where the observations are made. The library, laboratory, [illegible] offices [illegible] are in the valley below. For solar observations [illegible] telescopes—one 150 ft. high and one 60 ft. high—are used. A revolving mirror, known as a coelostat, and a fixed mirror on the top of the tower reflect the sun's light through an object glass downward. In each of the towers the spectrograph is mounted in a well under the tower, the depth of the well being one-half the height of the tower. With these instruments a continuous photographic record of the sun's surface is maintained day after day. This observatory has two large reflecting telescopes, one having a mirror 60 in. in diameter and one with a mirror 100 in. in diameter. The 100-in. telescope has been used with an interferometer for measuring the diameters of stars and has served for a great variety of researches. Optical arrangements for both telescopes provide for the use of different focal lengths in the Newtonian, Cassegrain or coudé form, and include powerful spectrographs. Additional instruments are a horizontal solar telescope, a 50-ft. interferometer, and 10-in. and 5-in. photographic refractors.

Another large U.S. observatory is the McDonald observatory of the University of Texas, Austin. Established in 1939 on Mt. Locke, 6,828 ft. above sea level, in the Davis mountains of Texas, it was organized under a co-operative agreement between two universities, the University of Texas building the observatory and the University of Chicago providing the scientific staff. The mirror is 82 in. in diameter and is mounted in a telescope of the cross-axis type, with the tube situated on the side of the polar axis. There is a prime-focus camera used for direct photography at the focus of the 82-in. mirror, without other reflections such as are common in a Newtonian telescope. A second camera provides for direct photography at the Cassegrain focus. Spectrographic equipment includes a slitless spectrograph for low-dispersion spectra, a spectrograph for use at the Cassegrain focus and a coudé focus spectrograph for high-dispersion spectra. The program at McDonald has been mainly spectrographic. The Perkins observatory was founded at Ohio Wesleyan university, Delaware, O., in 1924. It was equipped with a 69-in. reflecting telescope and was operated jointly with Ohio State university. In 1960 the instrument was moved to Flagstaff, Ariz.

Palomar Observatory.—This observatory was built by the California Institute of Technology to which the General Education board of the Rockefeller foundation made a grant in 1928 for the construction of a 200-in. reflecting telescope. Its operation is under a joint co-operative plan between the California institute and the Mt. Wilson observatory of the Carnegie institution. It is located at an elevation of [illegible] ft. on Palomar mountain, which is [illegible] from Mt. Wilson. The combined institutions are [illegible] termed Mt. Wilson and Palomar observatories. The dome and building for the great telescope were erected in [illegible]. The dome, which is 137 ft. high and of about the same diameter, is insulated throughout to protect the telescope from change of temperature when not in operation. The building which supports the dome has three floor levels on which are offices, photographic rooms, air-conditioning units, electrical switchboards and [illegible] and a large vacuum chamber for aluminizing the 200-in. mirror.

In the centre of the building, rising to the height of the third or operating floor, is the heavy structural steel framework which supports the two pedestals carrying the telescope. The frame or yoke in which the tube rests is rectangular in shape with tubular side members 10 ft. in diameter. A unique feature is the horseshoelike form of the north member of the yoke which permits the telescope to be turned northward as far as the north pole. The lower surface of this member is accurately [illegible] and serves as the north-bearing surface of the telescope mounting. The tube and frame, weighing a total of about 500 tons, are carried on a system of bearings employing high pressure oil pads which nearly eliminate friction and [illegible] ease of motion.

The tube, 22 ft. in diameter, is designed to avoid angular deflections at its ends and thus to reduce [illegible] effects of flexure. Uniform driving of the telescope is accomplished by a synchronous motor fed by current generated by a vibrating string standard and [illegible]

The disk for the 200-in. mirror is a single block of Pyrex glass cast by the Corning Glass works. It consists of a surface plate about [illegible] in. thick supported by a network of deep ribs. An opening 40 in. in diameter is cast in the centre of the disk. The fin-

ished mirror weighs about 16 tons. In the first grinding to spherical form in 1938, more than five tons of glass were removed. The slow and difficult work of parabolizing the surface was interrupted by World War II. The mirror was completed and installed in 1948. This instrument, named the Hale telescope, is used in two forms: primary focus with focal length of 55 ft.; and coudé combination, equivalent focal length 500 ft. In addition to the Hale telescope, the Palomar observatory put in operation a 48-in. telescope of the Schmidt type, working at ratio F/2.5 and utilizing a 72-in. concave spherical mirror. Smaller instruments include an 18-in. Schmidt telescope and a 20-in. reflector.

Other Observatories.—Canada has a 72-in. reflector at the Dominion Astrophysical observatory established in 1916 at Victoria, B.C., as a branch of the Dominion observatory at Ottawa, which itself had grown from a modest establishment used by the survey department. The telescope has been devoted chiefly to astrophysical work. In 1935 this size was surpassed by the 74-in. Pyrex mirror at the David Dunlap observatory of the University of Toronto. In spite of a rigorous climate this reflector has performed admirably.

In the eastern hemisphere an observatory specially adapted for solar investigation was established in Canberra, Austr., by the federal government of Australia as a link in the chain of such institutions around the world, of which the Solar Physics observatory at Cambridge, Eng. (moved from South Kensington in 1911), and that at Kodaikanal, southern India (which was established as a government institution about 1900 and replaced, in part, the observatory of the government of Madras founded in 1792), are others. The D. O. Mills expedition from Lick observatory established a 37-in. reflecting telescope at Santiago, Chile, in 1903 for spectroscopic study of southern stars. This station was discontinued in 1929. The former Harvard southern station, located near Bloemfontein, S.Af., is known as the Boyden observatory and is operated jointly by six northern institutions: Armagh, Dunsink, Hamburg, Harvard, Stockholm and Uccle. It has a 32-in. reflecting telescope of the Baker-Schmidt type and a 60-in. reflector, one of two in the southern hemisphere. The other is at the National observatory, Córdoba, Arg. Yale university set up a southern branch in 1925 at Johannesburg, S.Af., where a 26-in. photographic refractor was used for measuring stellar parallaxes. It was transferred in 1955 to Mt. Stromlo, Austr., to be used jointly with Columbia university. The University of Michigan established a branch at Bloemfontein in 1927, primarily for the study of double stars. The principal instrument is a 27-in. refractor. From 1954 to 1958 it was used by the Lowell observatory for the study of Mars. The observatory of the Republic of South Africa at Johannesburg has a 26-in. refractor. The largest instrument in the southern hemisphere is the 74-in. reflector of the Radcliffe observatory at Pretoria, S.Af., in operation from 1948. A telescope of equal dimensions was placed in operation in 1955 at the Mt. Stromlo observatory, near Canberra, Austr. In 1942 the National Astrophysical observatory in Tonantzintla, Mex., was dedicated. Its principal instrument is a 22-in. reflecting telescope of the Schmidt type.

Some notable additions were made to the observatories of Europe in the first quarter of the 20th century. Since the climate of Pulkovo, U.S.S.R., was considered to be unfavourable for observation, three branch establishments were founded through the influence of Oscar Backlund, its director: at Odessa (1898) and Nikolayev (1912), for astronomy of position, and at Simeis in the Crimea for astrophysical work. Backlund died in 1916, but in his last years the Russian government sanctioned the expenditure of large sums of money for equipment for the new observatories, and during 1926 a reflecting telescope with a mirror 1 m. in diameter and a photographic refractor with an objective of 41-in. aperture were supplied to the Simeis observatory by a British firm. The observatory of Geneva, Switz., which is of very early foundation (1772), possesses a reflector with mirror 1 m. in diameter, the gift of a member of the staff. The Astrophysical observatory at Potsdam, Ger., which dates from 1878, was enriched by the addition of a 32-in. photographic refractor in 1899, and in 1921 a tower telescope was erected on its grounds as a tribute to Albert Einstein.

A tower telescope was set up at the Royal Astrophysical observatory at Arcetri (Florence) designed for solar observation. A new object glass was supplied to this institution in 1925 by the German government, by way of war reparation. The Italian Royal observatory at Milan, with which the name of Giovanni Virginio Schiaparelli is associated, was removed and improved by the help of resources similarly supplied. The observatory at Bergedorf, Ger., 5 mi. S. of Hamburg, developed out of a local school of navigation in the city of Hamburg. Contributions by the citizens for instruments enabled the school to grow into the Hamburg municipal observatory. In 1906 it was transferred to Bergedorf and the new establishment was completed in 1909. In addition to instruments used for time service, there is a reflector, 1 m. in aperture, and a large twin telescope for photography. This observatory has been especially successful in the discovery of comets.

In Great Britain, transfer of the Royal Greenwich observatory to Herstmonceux castle in Sussex began after World War II and was completed in 1958. The original site at Greenwich, now surrounded by the city of London, is a park, but the main building designed by Wren has been preserved. The Norman Lockyer observatory, originally the Hill observatory, is on the top of Salcombe hill near Sidmouth, Devon. It contains instruments from the observatory of Frank McClean at Rusthall, near Tunbridge Wells, and others used at the government establishment formerly at South Kensington. The spectroscopic classification of stars and the determination of their parallaxes from examination of their spectra were covered in its program.

In 1914 at the Allegheny observatory, Pittsburgh, a 30-in. long-focus photographic refractor was completed. This instrument, at mid-20th century still the largest of its kind, has been used almost wholly for measurement of stellar parallaxes. A 37-in. reflecting telescope was installed at the University of Michigan in 1911. At the Lick observatory, a 120-in. reflecting telescope was completed in 1959. Schmidt-type telescopes of 24-in. aperture were placed in operation at Warner and Swasey observatory, Case Institute of Technology, Cleveland, O. (1941), and at the University of Michigan (1950). The McMath-Hulbert observatory, also a part of the latter institution, has been devoted primarily to the study of the sun. It has two tower telescopes (40-ft. and 70-ft.), the larger equipped with a vacuum spectrograph.

With funds granted by the National Science foundation, the Association of Universities for Research in Astronomy (A.U.R.A. established the Kitt Peak National observatory in Arizona. The principal instruments are an 84-in. reflector and a giant solar telescope, in which the sun's light is reflected down an inclined 300-ft tube and tunnel. In 1964 A.U.R.A. began construction on the Cerro Tololo Inter-American observatory in Chile.

The Haute Provence observatory at St. Michel in southern France has a 77-in. reflector, completed in 1958. An observatory of an unusual type was established in France in 1930 by Bernard Ferdinand Lyot of Meudon, who set up his apparatus on the Pic du Midi in the Pyrenees mountains at an elevation of 9,300 ft. There, with a special refracting telescope and optical system of his own design, he obtained remarkable results in the photography of the solar corona, prominences and spectrum of the corona in full sunlight. Using a cinematograph, he was able to record the movements of the prominences by means of motion pictures. A station of the Harvard observatory using equipment of a type similar to that of Lyot was established at Climax, Colo., in 1940. This became the high-altitude station of the University of Colorado. A still more elaborate solar observatory of similar type was established by the U.S. air force in 1951 at Sacramento Peak, N.M.

At the Karl Schwarzschild observatory near Jena, East Germany, a 79-in. reflector was completed in 1960.

In 1964 plans for two new major observatories were announced. The European Southern observatory is a co-operative undertaking by astronomers of Belgium, France, the Netherlands, Sweden and West Germany. A site was selected in Chile, and plans called for several large instruments, including a 140-in. reflector. The other observatory was to be established in Canada by the Canadian government, and a 150-in. reflector was planned.

Several special observing stations for tracking artificial satel-

lites were established at widely separated locations by the Smithsonian Astrophysical observatory, with headquarters at Cambridge, Mass. Operation of these stations began during the International Geophysical Year (*q.v.*), 1957–58.

In World War II many observatories in continental Europe and some in England were damaged. Two great Russian observatories, Pulkovo and Simeis, were almost totally destroyed. Restoration of the Pulkovo observatory was completed in 1954. New and modern equipment has been added to the larger observatories in the U.S.S.R. since World War II. The Crimean Astrophysical observatory has a 50-in. reflecting telescope at Simeis, and a 104-in. reflector was completed in 1960 at Nauchny in the Crimea. The Sternberg Astronomical institute at Moscow and the Byurakan observatory in Armenia are the other major institutions. Noteworthy solar installations are operated at the universities of Leningrad, Lvov and Kharkov.

Radio Observatories.—Radio waves from space were first recorded in 1931 by Karl Jansky of Bell Telephone laboratories, using a directional antenna. Additional pioneering work was done a few years later by Grote Reber, who employed a 30-ft. parabolic reflector of his own construction, at Wheaton, Ill. These installations, though only temporary, deserve recognition as the first radio observatories. Immediately after World War II, great activity in astronomical radio observations began simultaneously in Australia and in England. Most of this early work was done with instruments adapted from the equipment of installations for radar experimentation. After the first successes, design and construction of new "radio telescopes" specifically for astronomical research were begun. This development has proceeded with extraordinary rapidity and recalls the burgeoning of astronomical spectroscopy in the later years of the 19th century.

A radio observatory departs considerably from the traditional plan of an astronomical institution. Instead of a main large building surmounted by domes housing the instruments, the radio observatory consists primarily of the bulky instruments themselves, sometimes spread over many acres, in addition to a comparatively small building to house the recording equipment and a workshop. The offices of the observatory may be located a number of miles from the observing station. Because a radio observatory is not hampered by cloudy weather, continuous automatic recording is possible. However, electrical disturbances can be a serious handicap, and the site for a radio observatory must be chosen at a sufficient distance from industrial establishments.

The largest radio observatories were developed independently of already existing astronomical institutions. One of the foremost is the Radiophysics laboratory at Sydney, Austr., whose two "Mills cross" antenna arrays have dimensions of 1,500 and 3,500 ft. A steerable paraboloid 210 ft. in diameter was completed at Parkes, Austr., in 1963. At the Jodrell Bank experiment station of the University of Manchester, the largest fully steerable paraboloidal radio telescope, with a diameter of 250 ft., began operation in 1957. The Cavendish laboratory, Cambridge, Eng., operates an interferometer-type system of four large paraboloids. On the European continent, the most extensive installation is that of the Leiden university observatory, whose large paraboloids have been used to map the distribution of hydrogen in the structure of the Milky Way. Other large instruments are an 83-ft. paraboloid at Bonn university, West Germany, and one of 72-ft. diameter at Moscow, U.S.S.R.

In the United States, the Naval Research laboratory, Washington, D.C., completed a 50-ft. precision paraboloid in 1952, and an 84-ft. one in 1958. The Harvard observatory has one of 60-ft. diameter. In 1959 an 85-ft. paraboloid was completed at the University of Michigan. In the Owens valley, the California Institute of Technology has two 90-ft. paraboloids that can operate as an interferometer. The National Radio observatory at Greenbank, W. Va., has fully steerable paraboloids 85 ft. and 140 ft. in diameter and a tiltable 300-ft. paraboloid that operates in the meridian. Fixed paraboloids have attained still larger dimensions. Ohio State university completed one measuring 360 ft. by 70 ft. in 1962, and one 400 ft. by 600 ft. began operation at the University of Illinois in 1963. In 1964 Cornell university completed a fixed spherical reflector with movable receiver at the Arecibo Ionospheric observatory in Puerto Rico. *See* also TELESCOPE, RADIO.

Observations from Balloons, Rockets and Space Probes.—Observations with instruments carried in rockets above the atmosphere became commonplace during the decade following World War II. Beginning in 1957, the Princeton university observatory made observations from unmanned balloons at 80,000 ft. and above, commanded by radio from the ground.

The successful launchings of the first artificial satellites by the Soviet Union and the United States were quickly followed by astronomical observations from space vehicles. Among the most noteworthy were the photography of the moon's far side by the U.S.S.R.'s Lunik 3 (Oct. 1959), observation of Venus by the U.S. probe Mariner 2 (Dec. 1962), and close-in photography of the moon by the U.S. Ranger 7 (1964) and Rangers 8 and 9 (1965). In July 1965 the U.S. Mariner 4 photographed Mars from about 10,000 mi. out. *See* also SPACE EXPLORATION.

OBSERVER CORPS, an organization of civilian volunteers who man observation posts and report, usually by telephone, to military authorities on the movement of aircraft that they observe. The Royal Observer corps played a major role in the defense of Britain during World War II. During the 1950s the corps took on the additional duty of measuring and reporting radioactivity in the event of a nuclear attack. The U.S. Ground Observer corps, organized during World War II, was discontinued in Jan. 1959 because of the rapid development of electronic means of detection. *See* AIR POWER.

OBSIDIAN, a natural glass of volcanic origin, usually black and of a chemical composition equivalent to granite. Obsidian, which has a vitreous lustre, was used by American Indians and many other primitive peoples for weapons, implements, tools and ornaments. Due to its fracture, like glass, conchoidal, with smooth curved surfaces and sharp edges, the sharpest stone artifacts were fashioned from obsidian. Centuries ago the Mayas used obsidian for mirrors. Obsidian in attractive and variegated colours is used as a semiprecious stone. It forms by rapid cooling of viscous lava, has a vitreous lustre and is slightly harder than window glass, or about 5.5 on the Mohs' scale (*q.v.*). The typically jet black colour is due to abundant closely spaced crystallites (microscopic embryonic crystal growths). So numerous are these tiny inclusions that the glass is opaque except on thin edges. Red and brown obsidian receives its colour from included iron oxide dust; whereas light gray shades may be due to abundant tiny gas bubbles or finely crystallized patches. Variegated types with banding or mottling in black and red or black and gray are common.

Most obsidian is associated with volcanic rocks and forms the upper portion of rhyolitic lava flows. Less abundantly it occurs

as thin selvages of dikes and sills. Well known are the obsidians of Mt. Hekla in Iceland; the Lipari Islands, off Italy; and Obsidian cliff in Yellowstone National park, Wyo.

Composition and Characters.—Most obsidians are extremely rich in silica and are roughly compositional equivalents of granite and rhyolite (*qq.v.*). Others correspond to trachyte, dacite, andesite and latite. Glassy rocks equivalent to basalt are rare and go by the name tachylyte instead of obsidian. The composition of natural glass may be approximated from its index of refraction (*see* also MINERALOGY).

Average index values for volcanic glass are: rhyolitic—1.495; trachytic—1.505; dacitic and andesitic—1.515; and basaltic—1.57. Glassy rocks are roughly 6% lighter than their crystallized equivalents, and their densities increase with index of refraction. Average density values for volcanic glass are: rhyolitic—2.37; trachytic—2.45; dacitic and andesitic—2.50; and basaltic—2.77.

In addition to the crystallites, which are too small to show polarizing effects under the microscope, obsidian may carry abundant microlites (tiny polarizing crystals) many of which are large enough to be identified as feldspar. Both crystallites and microlites, however, are more magnificently and abundantly displayed in pitchstone (*q.v.*).

Some obsidians carry numerous large, well-formed crystals (phenocrysts) of quartz, alkali feldspar and plagioclase, many of which contain abundant inclusions of glass. Less common are phenocrysts of biotite, hornblende or augite. With increase in number of phenocrysts these porphyritic glasses pass into a glassy rock called vitrophyre.

Many obsidians contain spherical aggregates (spherulites) up to several inches across but generally a small fraction of an inch in diameter and composed of radially arranged needlelike crystals (*see* SPHERULITE). Some of these spherulites consist of concentric shells separated by annular (ring-shaped) interspaces. Such structures are known as stone bubbles or lithophysae.

Characteristic of many natural glasses is a streaked or swirly structure consisting of bands or trains of phenocrysts, microlites, crystallites or spherulites and believed to have formed by flowage of viscous lava. Some flow structures consist of alternating bands of different coloured obsidian. In others layers of bubble-free glass alternate with highly visicular glass (pumice, *q.v.*).

Obsidian is relatively poor in water, generally containing less than 1% by weight. This water represents only part of that contained in the original melt, most having escaped as steam when the lava poured out on the surface. A small chip of obsidian heated under a blowpipe will fuse readily and lose its water by volatilization. A second heating, however, will show the material to be highly infusible. This experiment demonstrates the fluxing action of water in rock melts. Under high pressure at depth rhyolitic lavas may contain up to 10% water which helps to keep them fluid even at a low temperature. Eruption to the surface, where pressure is low, permits rapid escape of this volatile water and increases the viscosity of the melt. Increased viscosity impedes crystallization and the lava solidifies as a glass.

Chemical composition controls in large part the formation of glassy rocks. Natural glasses have compositions close to quartz-alkali feldspar (*see* QUARTZ; FELDSPAR; SILICON: *The Silicates*). They may reach very low temperatures without crystallizing, but at these low temperatures their viscosity may be high. Forced solidification at this stage by sudden cooling and loss of volatiles will favour the formation of glass, because high viscosity inhibits crystallization.

Volcanic glass is unstable and tends to change spontaneously. This change (devitrification) involves the transformation from the glassy to the crystalline state and the material loses its vitreous character and takes on a stony appearance. Geologically ancient glasses are very rare and most glassy rocks are of Tertiary (early Cenozoic) age or younger. There is good reason to believe that glassy rocks were abundant in ancient geological time, but nearly all of these have since become devitrified. Devitrification commonly begins along cracks in the glass or around phenocrysts. It may spread outward until eventually the entire mass has been converted to a finely crystalline aggregate composed mostly of quartz, tridymite and alkali feldspar. If no glass remains, it may be difficult to demonstrate that a particular rock was ever glassy. The presence of spherulites, lithophysae and perlitic cracks (*see* PERLITE) is generally considered good evidence for the former existence of glass.

Closely related to obsidian are perlite, pitchstone and pumice. It is believed that under favourable conditions obsidian may be converted to perlite by adding water. Often in such cases the only remnants of the original obsidian are found in the cores of the glassy perlite beads. For chemical analyses of obsidian and related glassy rocks *see* PITCHSTONE. (C. A. CN.)

OBSTETRICS is the branch of medicine that deals with human reproduction. In its broadest sense it encompasses the entire life cycle, for the creation of a new individual begins long before conception and life is a timeless process that continues in an unbroken line from parent to child.

Ideally speaking, the obstetrician's interest in the future mother should begin prior to puberty, continue through adolescence and maturity and culminate in pregnancy, delivery and the postpartum, or recovery, period. Modern medical practice, with its increasing emphasis on the prevention of illness, should include periodic examinations of the mother throughout her reproductive period and the postmenopausal years. The trend today, particularly among specialists, is to combine obstetrics with gynecology, which concerns itself with the prevention and treatment of diseases of the reproductive organs.

Maternity care is the major clinical activity of the obstetrician. The phenomenal reduction in the hazards of birth for mothers and babies has focused increasing attention on the emotional aspects of childbearing. Thus, education for parenthood prior to and during pregnancy has assumed great importance. The usual prenatal medical supervision designed to keep the mother in good health, to prevent pregnancy complications and to safeguard the normal growth and development of the baby is now supplemented by discussions, lectures and exercise programs. Knowledge concerning the birth process will dispel fear; relaxation and emotional support during labour and delivery and favourable body postures will decrease tension and discomfort, thereby reducing the need for anesthetics and the likelihood of complications. Thus, the normalcy of human reproduction is emphasized.

The modern education of every young physician includes instruction in the biological sciences and human reproduction as well as clinical experience in the management of normal pregnancy and delivery. He must learn to recognize incipient complications and be able to institute corrective measures.

In the U.S., the physician who wishes to prepare himself for the specialty of obstetrics must undertake formal postgraduate training in an approved institution for at least three years. The completion of this program is followed by oral and written examinations and if he passes them he is certified by the Board of Obstetrics and Gynecology as a specialist.

See also CHILDBIRTH; MATERNAL AND CHILD HEALTH; MIDWIFERY; and references under "Obstetrics" in the Index. (M. E. DS.)

OBWALDEN, a demicanton which, with Nidwalden, forms the canton of Unterwalden (*q.v.*) in central Switzerland. The population (1960) 23,135, is mostly German-speaking and Catholic. The capital is Sarnen (6,554). Unterwalden was one of the three cantons that founded the Swiss confederation in 1291. Obwalden includes the small lakes of Sarnen and Lungern and the ski resorts of Melchsee-Frutt and Engelberg. At Engelberg are the famous Benedictine monastery and church, founded about 1120.

OCARINA, a wind instrument, originated in Italy toward the end of the 19th century as a musical development from the traditional Italian carnival whistles of earthenware, often in the form of a bird and sounding only one or two notes. The ocarina (meaning "little goose") is made of earthenware or metal and is sounded on the flageolet principle.

HORNIMAN MUSEUM

ITALIAN OCARINA

It has eight finger holes and two thumb holes and sometimes a tuning plunger at one end. The instrument won professional popularity in the 1930s, when ocarinas or "sweet potatoes" of different sizes were played in harmony in U.S. popular music. It is still manufactured as a toy instrument. *See* also WIND INSTRUMENTS: *Flutes.* (A. C. BA.)

O'CAROLAN (CAROLAN), **TURLOGH** (TERENCE) (1670–1738), one of the last of the Irish harper-composers and the only one whose songs survive in both words and music in any significant number, was born near Nobber, Co. Meath. About 1684 the family moved to Ballyfarnon, Co. Roscommon, where O'Carolan's father was probably employed in the iron foundry of Henry MacDermott Roe. MacDermott Roe's wife was responsible for O'Carolan's early education. When, at the age of 18, he became blind from smallpox she apprenticed him to a harper and maintained him for three years. After he completed his apprenticeship, she provided him with money, a guide and a horse. As an itinerant harper he traveled widely in Ireland. He died at Alderford, Co. Roscommon, on March 25, 1738. O'Carolan enjoyed a considerable reputation as a song writer and composer of extemporary verse, though as a performer he was never regarded as a master. One of his melodies was used by Thomas Moore for his song "Oh! the sight entrancing." A selection of O'Carolan's verse in the original Irish was published in Tomás Ó Máille's *Amhráin Chearbhalláin. The Poems of Carolan* (1916).

See D. O'Sullivan, *Carolan*, 2 vol. (1958).

O'CASEY, SEAN (1880–1964), Irish playwright, whose dramas of the Dublin slums contributed to the later stages of the Irish literary renaissance, was born in Dublin on March 30, 1880. His early years were spent in great poverty and he worked as a casual labourer when not unemployed. The Dublin general strike of 1913 influenced his development. In 1923 *The Shadow of a Gunman* was produced at the Abbey theatre (*q.v.*), followed in 1924 by *Juno and the Paycock* and in 1926 by *The Plough and the Stars*. These three are by common consent his finest plays. The last-named was bitterly attacked in Ireland and in the year it was staged he left the country for good. His exile (in England) was confirmed two years later by the Abbey's rejection of *The Silver Tassie*, produced in London in 1929.

Subsequent plays include *Within the Gates* (1933), *The Star Turns Red* (1940), *Red Roses for Me* (1942), *Oak Leaves and Lavender* (1946), all treating social themes in a more expressionist manner than his earlier work; the extravaganza *Cockadoodle Dandy* (1949); and two satirical comedies about clericalism in Ireland, *The Bishop's Bonfire* (1955) and *The Drums of Father Ned* (1958). He also wrote six tumultuous volumes of autobiography: *I Knock at the Door* (1939), *Pictures in the Hallway* (1942), *Drums Under the Windows* (1945), *Inishfallen Fare Thee Well* (1949), *Rose and Crown* (1952) and *Sunset and Evening Star* (1954). He died on Sept. 18, 1964, at Torquay, Eng.

O'Casey's later plays are in general too partisan, too didactic and too overtly "poetic" to be entirely successful, though many contain scenes of great beauty and comic power. It is on his early plays, with their tragic-comic picture of Dublin tenement life during the "troubles," their wonderful range of comic characters and their impartial celebration of all the contradictory elements of the human spirit, that his reputation principally rests.

See D. Krause, *Sean O'Casey: the Man and His Work* (1960); S. Cowasjee, *Sean O'Casey* (1963). (A. CR.)

OCCASIONALISM, in the philosophy of the Cartesians (*q.v.*), is the argument that God is the sole efficient cause, created things being merely "occasional" causes. Beginning as an answer to the problem of the union between soul and body (*see* BODY AND MIND; DUALISM), it expands this answer to cover the relationship between all finite substances. In the early polemics on occasionalism reference was made to passages in the works of Philo Judaeus, Pierre d'Ailly and Gabriel Biel which Francisco Suárez had criticized and to passages in certain Arabic writings which St. Thomas Aquinas had criticized; but these occur in contexts very different from that of the Cartesian problem.

René Descartes (*q.v.*) not only takes a radically dualistic view of soul and body but also holds the mechanistic concept of matter as an essentially inert extensity or extension, in which movement is kept in being by God, its original and general cause (*Principia*, ii, 37–38; letter to the marquess of Newcastle, Oct. 1645). Yet Descartes maintains the notion of the "concourse" of secondary causes; and if he describes bodily stimuli as "giving occasion" to the soul to experience certain feelings (*L'Homme*), he still affirms that there is a "substantial union" with reciprocal action between soul and body. Only a few Cartesians, however, namely those with a tendency to empiricism, Pierre Sylvain Regis and Robert Desgabets, claim that we have experience of this union, the body's instrumental causality not precluding a real dependence of the body on the soul. The other followers of Descartes go back to the principle of all activity in order to explain the nexus between the two heterogeneous terms.

For Johann Clauberg (*q.v.*) the mutual and reciprocal conjunction between one component's activity and the other's passivity takes effect from God's will, which makes them succeed one another. Arnold Geulincx (*q.v.*) insists particularly on the argument *Quod nescis quomodo fiat, non facis* ("You cannot be said to do anything unless you know how it comes to be done") and criticizes the alleged consciousness of effort: my body, the "occasion" for me to perceive other bodies, is an instrument intermediary between the sole efficient Cause and my thought. Louis de La Forge (*Traité de l'esprit de l'homme*, 1666) is the first to use the term "occasional cause" for the impression of the body in the production of ideas by the soul, which is the principal and effective cause: he thus keeps the traditional notion of the soul's "power" after having extended the notion of inertia to the mind, but goes back to God to explain the transition from one idea to another (in his conversations of 1658 as recorded in Jacques Gousset's posthumous *Causarum primae et secundarum realis operatio*, 1716). In 1666, making the point that the will to move the body does not act "directly or by itself," La Forge speaks of "reciprocal dependence" between soul and body. Géraud de Cordemoy carries occasionalism even further: God is the universal cause, and when one body seems to move another we can only register a succession of movements, the meeting of the bodies being an occasion for the Mind which is moving the first body to move the second. Thus "God does all that is real in our actions, without depriving us of freedom." Thenceforward occasionalism becomes the distinguishing mark of the Cartesians. One of their antagonists, the Jesuit Antoine Rochon (*Lettre d'un philosophe à un Cartésien*, 1672), protests that their argument about bodily motion could logically be applied to make God the author of all the motions of our minds.

It was Nicolas Malebranche (*q.v.*) who, by systematizing its various elements, established occasionalism as a "Christian philosophy" in opposition to the pagan view of nature and secondary causes as so many minor divinities. Developing his precursors' themes (the absence of any intelligible relationship between soul and body; criticism of the illusory consciousness of direct action on bodies; and the reduction of the impact of two bodies to their successive positions), he points out that we have no clear idea of the soul and no common measure for will and ideas, but that we have clear knowledge of an extensity void of all internal dynamism. Furthermore, God's action on created things must obviously be both necessary (continuous creation) and sufficient, so that any other efficient cause is superfluous. Occasional causes, meanwhile, can be shown to determine the application of "general laws," those of nature and those of grace alike. Under those of nature he includes not only the communication of movement, but also the rational union of the soul to God or the vision of ideas in God, with its occasional cause in the act of attention (our attention also determines the general movement whereby God inclines us toward the good, so that our freewill is preserved). For general laws of grace, examples are the occasional causality of angels in the miracles of the Old Testament and the particular manifestations of the will of Jesus Christ, occasional cause of the distribution of graces, in the New.

Johann Christoph Sturm (1635–1703), professor of mathematics at Altdorf, upheld occasionalism in his works *De naturae agentis idolo* (1692) and *De natura sibi incassum vindicata* (1698) against criticism by the physician Günther Christoph Schelham-

mer. G. W. Leibniz (*q.v.*) broadened this field of criticism by propounding a dynamism of his own: notwithstanding some external resemblances (for instance the denial of reciprocal influence between created substances), his "pre-established harmony" is quite different from occasionalism, which, despite Malebranche's specification of general laws, he accuses of postulating a "perpetual miracle." Likewise there is no way of reconciling occasionalism with the parallelism of the "attributes" according to Spinoza (*q.v.*), who, instead of making action in the body correspond to passion in the soul, or *vice versa*, holds that the same transition from passion to action comes about in thought and in extension singly, thanks to the internal dynamism of the *conatus* and to the immanent unity of Substance as a whole, which takes the place of a transcendent First Cause.

Detached from their theological context, the Cartesians' arguments for reducing the causality of created things to a succession of "occasions" paved the way for the empiricist approach of David Hume. *See* CAUSALITY.

OCCUPATIONAL THERAPY has evolved from the recognition that work helps to restore the mentally and physically ill. It was observed that many patients at mental hospitals benefited from working in the establishments' utility services. In the latter part of the 19th and early years of the 20th centuries the first experiments were made in the use of crafts as a means of occupying the inmates of mental hospitals. This gave rise to the idea of workshops and in 1908 the first occupational therapy workshop was opened in Chicago.

General or diversional therapy is the prescribed use of activities, especially in the treatment of patients where boredom and depression are concomitant with a prolonged period in bed or confinement in hospital or at home. Often it can aid patients to realize and to discover latent abilities. Light crafts such as painting, needlework and weaving are the usual skills employed and the development of a high craft standard contributes to the satisfaction and well-being of the patient.

Specific therapy is that prescribed by the physician or surgeon for a specific remedial purpose, the scope being wide and varied. Physically the prescription is usually aimed at the increase of joint motion, strength of muscle or development of co-ordinative motor skills and work tolerance. These may also be required for the psychiatric patient, with the addition of reorientation and alleviation of stress, anxiety states and hysterical physical symptoms. Heavier crafts are used to obtain specific movements.

History.—World War I brought opportunity for development and introduced the need for work in the field of physical illness. Initially the prime consideration was to relieve the monotony of wounded men confined to bed for long periods, but it was soon observed that certain activities not only created a better morale but also increased the mobility of injured limbs, and it became the custom to order craft activities as part of the treatment.

Until this time, supervision and instruction were given by craftsmen and craft teachers without any medical knowledge; but it was clear that in order to expand the work and meet the new need personnel would have to be specially trained. The first schools of occupational therapy were started in Philadelphia and Boston, although in the Netherlands and the United Kingdom staff members were being trained in hospitals and curative workshops.

Elizabeth Casson set up a workshop in Bristol, Eng., sent one of her staff members to the U.S. to train and then began training students at Dorset House in Bristol. In London the Occupational Therapy Centre and Training school was inaugurated and these two centres continued until World War II, when Dorset House was evacuated to Bromsgrove eventually moving to Oxford, where it remained. The London Occupational Therapy centre had to suspend its activities, because of bombing, for a period, after which time it resumed in new premises.

Between the wars the scientific application of craft activities for the treatment of both mental and physical conditions developed simultaneously, but with the advent of war and the resultant casualties, among both sevicemen and civilians, the demand in the U.K. for therapists trained in the physical field outran the training capacities of the two schools. An emergency training scheme was inaugurated that continued until the end of the war. The Association of Occupational Therapists in England and the Scottish Occupational Therapy association were formed as examining bodies and, with the advent of the National Health service, became officially recognized for the U.K. After 1952 no occupational therapist could work in the National Health service unless qualified with either of these associations or with certain overseas bodies, and after 1963 state registration was obligatory in the U.K.

In the U.S. the American Association of Occupational Therapists sets an examination for registered therapists, but in some states a therapist before practising must pass a state registration examination as well. Similar developments occurred throughout the world, especially in the Scandinavian countries, the Netherlands, Belgium, Australia, New Zealand and Canada.

In 1952 the decision was made to form a World Federation of Occupational Therapists and in 1954 the first international congress of occupational therapists was held in Edinburgh. The second world congress was held in Copenhagen in 1958, when more than 30 countries were represented. The third world congress was held in Philadelphia in 1963, when 37 countries were represented.

The World Federation of Occupational Therapists is an associate member of the Conference on World Organizations Interested in the Handicapped, a conference of nongovernmental organizations pertaining to the rehabilitation program of the United Nations and the World Health organization. It publishes documents as a guide to the setting up of new schools in countries where occupational therapy is being developed and lays down minimum standards for training.

Modern Activities.—The occupational therapist, in order to carry out the treatment prescribed by the physician, must have adequate knowledge of anatomy, physiology, medicine, surgery, psychiatry and psychology, as well as knowledge of the skills used as treatment measures. A period of supervised clinical experience is required in order to learn to apply in practice the subjects learned in theory. The qualified occupational therapist is trained to treat either physical disabilities or mental illness; these two large divisions provide many specialized fields requiring further study and experience. In both areas, however, the work is divided into the following two main classifications: (1) vocational evaluation and (2) rehabilitation for daily living.

Vocational Evaluation.—To rehabilitate and resettle the disabled, either for return to work or for home employment, it is essential to assess their ability to work. Methods vary from simple activity tests to full-scale work tests and psychiatric assessment. In the U.S. particularly, objective methods of work sampling were evolved in several centres. These samples used tests related to industrial processes and to known working norms and provided a scientific basis on which the rehabilitation officer and employment agencies could evaluate the patient's work potential.

After assessment some prevocational training or practice may be necessary and many occupational therapy departments have units where the patient may be taught, or gain experience in, the use of tools for trades (*e.g.*, woodwork), light industrial work (*e.g.* light assembly work) and clerical duties (typing, etc.). After initial training many are transferred to further training centres or direct to industry, others to employment in sheltered workshops maintained by government or voluntary agencies, and some to work at home. These last require training to a standard sufficient to enable them to command fair wages as outworkers. The type of work selected depends on local employment conditions.

Occupational therapy is vital for reorienting patients hospitalized or unemployed for long periods. Such patients must learn afresh to mix and work with other people, to work to time schedules, and to cope with the problems of traveling to work. The occupational therapist advises on how difficulties may be overcome and provides escort and encouragement until the patient regains confidence.

Rehabilitation for Daily Living.—An equipped kitchen unit is a standard part of most modern occupational therapy departments, and many centres have a "flat" so that practice in home care can be provided for the housewife before she resumes her duties after a serious accident or long illness. Here the cardiac patient, for example, can be taught how to avoid undue exertion by the placement of working equipment at heights that avoid the need for lifting or reaching. Working heights can be checked to minimize back strain for those with spinal injuries. The arthritic and hemiplegic can try out variations of padded handles and be shown methods of moving pans and heavy articles, so that painful joints and weak muscles may be relieved of strain.

The difficulty of caring for an elderly chronically sick relative in the home is increased when there is insufficient help in the home, especially when the women of the family are employed outside the home. When the patient is able to care for himself the difficulty is minimized. Occupational therapy provides not only the sphere for training in daily living activities but also help in provision of aids that make eating, dressing and toilet less fatiguing for the elderly or chronically sick. One of the unique features of occupational therapy in the U.K. is the widely developed service of domiciliary occupational therapy, which provides many homebound patients with assistance in their problems of daily living, a social contact and in many cases a source of income through the provision of work.

Possible Future Development.—The fields most likely to be developed are those that make people more active and employable: the provision of help and guidance for the elderly and chronically sick and their employment in such agencies as the Golden Age centres and workshops provided by voluntary organizations in the U.S. and the occupation centres and sheltered workshops of the U.K. The wider use of domiciliary occupational therapy is also to be expected. Younger patients are helped by rehabilitation centres that give a quick and vigorous program of re-education after hospital treatment, and by centres for work evaluation.

OCEAN AND OCEANOGRAPHY. The ocean (also called the world ocean or the oceans) is the interconnecting body of salt water which occupies 70.8% of the surface of the earth. An ocean is one of the major subdivisions of this sheet of water, lying between the continents. Smaller partially enclosed subdivisions of the oceans are called seas.

This article is divided into the following main sections:

I. INTRODUCTION

1. Oceanography and Its Scope.—Oceanography is the scientific study of the ocean in all its aspects. Although it may be regarded as a separate science, it actually is a common meeting ground of four sciences. It includes the physical study of the water and wave movements, the geological study of the form of the ocean basins and the characteristics of the sediments laid down in them, the chemical study of the water and dissolved substances and the biological study of the plant and animal life in the sea. Some writers have preferred the term oceanology to embrace all these fields, and thalassography has also been employed, but the weight of usage is behind the term oceanography. The similar study of lakes and other freshwater bodies is limnology.

Together with lakes, rivers, underground water and atmospheric water vapour, the ocean makes up the major division of the earth's surface known as the hydrosphere. The other divisions are: the atmosphere, or gaseous portion; lithosphere, or solid portion; and biosphere, or living portion. Although the physical aspects of oceanography are commonly included as one of the subdivisions of geophysics, the chemical aspects more properly belong to geochemistry, the geological aspects to geology and the biological aspects to the life sciences.

The word ocean came into English from the French *océan*, which in turn was derived from the Latin *oceanus* and Greek *okeanós*. The term was originally applied to the great river or outer sea that encompassed the ancient world of Eurasia and Africa, as distinguished from the Mediterranean and other inland seas. It was personified in classical mythology as the god Oceanus, son of Uranus (sky) and Gaia (earth) and husband of Tethys, a titaness. In 13th-century English the terms "sea of ocean" and "sea ocean" were often used, and later, down to 1650, the form "ocean sea" was common.

The word oceanography was first used in English by W. Dittmar in 1883; the German *Ozeanographie* (now often replaced by *Meereskunde*) is a few years older.

2. Significance of the Ocean.—The ocean serves and affects mankind in many ways. So vast is it that often these ways are contradictory. The ocean stores heat and water that have a profound influence on weather and climate; yet castaways at sea may die from cold or thirst. The sea is a barrier to invasion, so that island races have developed parliaments (Iceland in 930; Britain in 1275) and other democratic institutions when their continental kindred were still in feudalism. Likewise, the breadth of the Atlantic facilitated the winning of independence by the United States and the Spanish possessions in America, and the subsequent operation of the Monroe Doctrine. On the other hand, to those who master its technology, the sea is a means of communication. The frontiers of the United States and Canada were pushed east from the Pacific as well as west from the Atlantic because it was easier

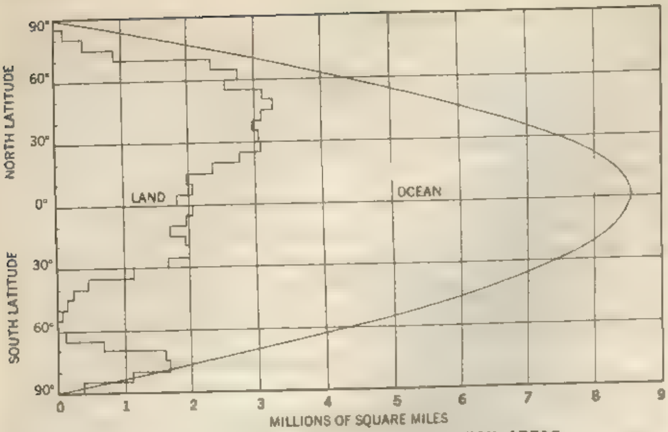

FIG. 1.—DISTRIBUTION OF LAND AND OCEAN AREAS

The smooth curve represents the total area of the earth's surface in each five-degree band of latitude

to sail around Cape Horn than to cross the continent overland.

The sea is an important source of food, particularly of animal proteins and fats; yet into it are dumped the sewage of seaside communities and even radioactive wastes. The sea serves for recreation and for the disposal of garbage. From its animals and plants are obtained not only precious jewels but also the raw materials for such prosaic items as paint, fertilizer and glue. Land and the fertility of the soil are lost to the sea and won back from the sea. Salt and chemicals are recovered from sea water, building materials from the nearby continental shelves, and coal, petroleum, gas and sulfur from shafts and wells drilled miles offshore in shallow water.

3. Causes of the Ocean.—In possessing an ocean, bordered by continents, the earth is probably unique among the planets and satellites of our solar system. To understand why this has come about, we need to ask three questions:

1. Why are there ocean basins? The answer to this question is that the rocks making up the outer portion of the earth's crust are not uniform in their properties or chemical constitution. Over large areas of the earth's surface, the rocks are characteristically light in colour and relatively light in weight. They are classed as granitic, since granite is the major rock type. Over larger areas, the rocks on the average are darker in colour and heavier in weight. These are the basaltic rocks, since among them basalt is the chief type. It is known from studies of the propagation of earthquake waves that the core of the earth at a depth of a few hundred miles below the surface has the properties of a fluid. The crustal rocks, about 50 mi. thick, in effect are floating on this liquid core. The areas of granitic rock, since they are lighter, stand higher than the surrounding areas of basaltic rock, just as a cork floats higher than a piece of wood the same size. The granitic areas thus form the continents, and the basaltic areas are the ocean basins. Were the crustal rocks of the earth uniform in composition, the earth's surface would consist of one vast ocean, more than a mile deep. Under such conditions, although an occasional volcanic island might form above the ocean surface, it probably would soon sink and disappear below the surface again, as the locally overloaded earth's crust adjusted to the strain by the process of isostasy (*q.v.*).

2. Why is there water in the ocean? Even if we have explained ocean basins, we have not yet completely accounted for the ocean. The moon, for example, though it is known to have suitable basins, has a bone-dry surface. The reason why there is water in the oceans is threefold. In the first place, molten rock, such as lava, holds much more water when liquid than when it hardens and cools. Thus, as the earth's crust has solidified during geologic time, water vapour has been given off to the atmosphere. Analyses of gases from volcanoes and fumaroles show that this process is still going on today. Something like this must have happened on the moon, yet the moon has no ocean. The explanation is that gravity is much weaker on the moon than on the earth. Gas molecules in the earth's atmosphere behave just as does any other moving body with respect to the earth's gravitational field: if the escape velocity of 7 mi. per second is exceeded, the body can escape to outer space. At the boiling point of water (212° F.) the mean speed of water molecules is only 0.4 mi. per second, and the probability that any molecule may have $17\frac{1}{2}$ times this speed at this temperature is infinitesimally small. Therefore, even if fairly high temperatures exist in the upper atmosphere, the earth does not lose water molecules. For the moon, where a temperature of 212° F. is regularly exceeded on the face presented to the sun the escape velocity is only 1.4 mi. per second. At 212° F., one water molecule has this speed for every 60,000 having the mean speed. Thus the moon fails to hold water vapour or the other light gases that make up our atmosphere and hydrosphere and hence it lacks an ocean. The second reason that there is water in the ocean, therefore, is that the earth's gravity keeps the water from escaping into space, just as it also retains the air we breathe. As the third reason, the pressure-temperature relationships on the earth's surface are such that the water is mainly in liquid form. Conceivably the atmosphere could be so hot that all the water existed in vapour form. A temperature of at least 705° F. (the critical temperature of water vapour) would be necessary, and the corresponding atmospheric pressure would then be of the order of 5,500 lb. per square inch. On the other hand, if the earth's temperature at sea level never exceeded 32° F., the ocean basins would be filled with solid ice. Since there still would be water vapour in the atmosphere, and snow still could fall, a vast continental glaciation might take the place of the present river drainage system. Since neither of these extreme temperature conditions exists, we have the ocean in its present form.

3. Why is the ocean salty? The salts in the ocean are one result of over 2,000,000,000 years of disintegration of the igneous rocks of the earth's crust. The soluble materials remain in the ocean; the insoluble precipitates have formed sedimentary rocks and the ocean sediments. The ocean contains all the elements originally present in the igneous rock to the extent that they are soluble, are not adsorbed on clay or are not removed by biological activity. Suspended material and dissolved salts, extracted from the rocks of the continents, are still delivered to the sea by rivers. Much of this eroded material is from sedimentary rocks that have previously passed through the same cycle. Equivalent amounts of new sediments are being laid down at the same rate. The result is that the sea is in a steady state with regard to the composition of its salt, and it has probably maintained a close approximation to this present composition for millions of years.

When changes in drainage pattern and climate cut off lakes from their outlets to the sea, they soon become salt lakes. Great Salt lake in Utah is an example. Standing over 4,200 ft. above sea level, it never was part of the ocean. Evaporation keeps it from overflowing, the salts leached out of the surrounding mountains remain behind, and, in the approximately 100,000 years since its parent Lake Bonneville became isolated, the Great Salt lake has become eight or ten times as salty as the ocean. Most of the world's other salt lakes, such as the Dead sea, Caspian sea and Aral sea, have acquired their salt in this fashion, independently of

TABLE I.—*Percentages of Water for Each Latitude Band*

Latitude band	Total area (000,000 sq.mi.)	Percentage covered by sea	
		Northern hemisphere	Southern hemisphere
0° to 5°	8.542	78.6	70.4
5° to 10°	8.479	75.7	75.4
10° to 15°	8.352	76.5	76.4
15° to 20°	8.164	70.8	79.6
20° to 25°	7.915	65.2	70.9
25° to 30°	7.606	59.6	75.9
30° to 35°	7.239	57.7	84.2
35° to 40°	6.817	56.8	93.4
40° to 45°	6.342	51.2	96.4
45° to 50°	5.818	43.8	97.5
50° to 55°	5.249	40.7	98.5
55° to 60°	4.638	45.0	99.9
60° to 65°	3.990	31.2	99.7
65° to 70°	3.310	28.7	70.5
70° to 75°	2.602	65.5	38.0
75° to 80°	1.874	77.1	10.7
80° to 85°	1.131	85.2	0.0
85° to 90°	.378	100.0	0.0
Whole hemisphere	98.446	60.6	81.0

Aerial view shows erosive power of the sea along the Dutch coast. The sea curls inland cutting deep channels and sweeping away land: low tide reveals plains of mud and sand

An English beach at low tide. The rise and fall of the tides is related to the positions of the sun and moon

Belching smoke and steam, a new volcano emerges from the sea on the Myojin reef 170 mi. S. of Tokyo, Japan

Sand from nearby beaches, carried by currents, cascades down the walls of the Cape San Lucas submarine canyon off Lower California

Photograph taken by deep-sea camera shows a sandy portion of the western Indian ocean bottom at 1,756 fathoms. Ripples in the sand are caused by bottom currents

THE SEA

FIG. 2.—THE WORLD OCEAN, SHOWING THE INTERCOMMUNICATING NATURE OF THE OCEAN BASINS

The white zones are deeper than 13,000 ft., the approximate average depth of the ocean. Contours of dissolved oxygen, in volumes per 1,000 vol. of sea water (ml./l.), are also shown

the ocean. They represent oceans in miniature.

II. THE OCEAN BASINS

1. Distribution of Land and Sea.—The relative distribution of land and sea in relation to latitude is of fundamental importance in understanding how the ocean behaves as a whole. Thus, the north polar region is an ocean basin which communicates chiefly with the North Atlantic and is connected to the Pacific only by the shallow Bering strait. The south pole, on the other hand, is on land, but is surrounded entirely by water, which communicates with all the other oceans. Fig. 1 illustrates the relative proportion of land and water areas of the earth, while fig. 2 shows how all the ocean connects in the Antarctic. The percentages of water for each latitude band are given in Table I (after Erwin Kossinna).

2. The Seven Oceans.—The term "seven seas" is often encountered in the works of medieval Arabic geographers. The Turkish hydrographer Piri Reis in the 16th century listed them as the South China sea, Bay of Bengal, Arabian sea, Persian gulf, Red sea, Mediterranean sea and Atlantic ocean. These were the waters of the Mohammedan world prior to the fall of Constantinople (1453). The phrase appeared in E. FitzGerald's translation of Omar Khayyam in 1859 and was popularized by Rudyard Kipling as the title of a book of verses in 1896.

It happens that, although there is considerable disagreement among various authorities as to the number and designations of the major subdivisions of the ocean, a very convenient arrangement is into seven oceans, as shown in Table II.

TABLE II.—*Major Subdivisions of the Ocean*

Ocean	Area in sq.mi.	Mean depth in feet
Arctic	5,427,000	5,010
North Atlantic	17,646,000	10,780
South Atlantic	14,098,000	13,420
North Pacific	31,639,000	14,050
South Pacific	32,361,000	12,660
Indian	28,400,000	13,002
Southern (Antarctic)	12,451,000	12,240

In this scheme, the equator is taken as the boundary between the North and South Atlantic and North and South Pacific; the Southern (Antarctic) is arbitrarily bounded by the parallel of 55° S.; and the meridians of Southeast cape, Tasmania, and Cape Agulhas, S.Af., determine the limits of the Indian ocean, South Pacific and South Atlantic. The further breakdown of the ocean into seas, gulfs and straits has been the subject of careful study by the International Hydrographic bureau, whose *Publication No. 23* should be consulted for details. The total area of the ocean is 142,022,000 sq.mi., total volume 328,750,000 cu.mi. and mean depth 12,450 ft.

3. Ocean Depths.—Relative to the size of our planet, the ocean forms hardly more than a wet film over the part of the earth that it covers. To visualize the true scale of the Pacific between Panamá and Manila or Yokohama and Callao, let the thickness of an ordinary pencil mark ($\frac{1}{16}$ in.) represent the average depth of the ocean. Then to represent the distance of over 8,000 mi. on this same scale, we must continue the pencil line for 5 ft. Or, on the blackboard, if we are to represent the average depth of the Atlantic by a chalk line $\frac{1}{8}$ in. wide, to cover the distance from Jacksonville, Fla., to Southampton, Eng., we will need to make the line 56 ft. long.

We must not infer from this picture of the ocean that its bottom consists only of vast level plains. Although it is true that river drainage systems, the chief factors in shaping the land, do not exist under the sea, there are still mountain ranges and canyons, basins and ridges, and peaks and valleys as well defined as any on land. We cannot see these features with our own eyes, as we can the land features, and only the painstaking tabulation and plotting of ocean soundings make them apparent.

Fig. 3 shows that the deepest ocean is much farther below sea level than the highest mountain is above. This figure is the hypsographic curve of the earth's surface. It shows the area of the earth's solid surface above or below any given elevation or depth. The mean height of the dry land is 2,760 ft.; the mean height of the physical earth's surface is 29% of this or 800 ft.; the mean level of the crust of the solid earth is 8,000 ft. below sea level.

4. Sea Level.—Sea level, or more properly mean sea level, is the average height of the sea surface after all wave motion has been smoothed out. Since some of the highest waves are those of the tide, it is necessary to average observed tide levels for 19 years in order to eliminate all the astronomical influences on them (*see* TIDE).

Longer series of observations often show substantial changes in mean sea level with time. Thus along the east coast of the United States, sea level between 1930 and 1950 rose about one-fourth inch per year, or at the rate of two feet per century. This effect is generally attributed to the melting of polar icecaps, which are thereby adding more water to the ocean. In Scandinavia, on the other hand, tide gauges show that the land is rising relative to the water, and there the effect is explained as isostatic

nificant quantities of the oxides of cobalt, copper and nickel, forms crusts on any exposed projection above the bottom. These manganese nodules often contain as a core a shark's tooth or the ear bone of a whale, two types of skeletal remains that prove highly resistant to decay and redissolving on the ocean floor.

The oozes, defined as pelagic sediments with over 30% skeletal remains, are subdivided first into calcareous and siliceous oozes and then again according to the predominant skeleton type. Thus the calcareous oozes include globigerina ooze, containing the tests of planktonic foraminifera, and pteropod ooze, made up chiefly of the shells of pelagic snails. The siliceous oozes include radiolarian ooze, which is essentially red clay with more than 30% of the skeletons of warm-water protozoa, and diatom ooze, containing the frustules (tiny shells) of diatoms. The siliceous oozes exist only where the rate of supply of diatoms or radiolarians is greater than the rate of solution of silica in the deep waters; thus the diatom oozes are confined to productive belts in the North Pacific and Antarctic, and the radiolarian oozes are found only under the eastern part of the Equatorial current in the North Pacific. Except near the equator, the rest of the North Pacific is covered almost entirely with red clay. The other oceans have both red clay and globigerina oozes. Pteropod ooze is found only in mid-Atlantic. Seismic measurements indicate that there is a thickness of about 1,000 to 1,200 ft. of unaltered pelagic sediments in the deep oceans.

4. Rates of Sedimentation and Past Climates.—Various calculations have shown that the average rate of deposition of red clay is about one inch every 2,500 years, and rates for the other pelagic types of deposit are not much greater. It is technically quite feasible to lower sharpened pipes to the bottom and drive them in to depths of 70 ft. or more, and thus samples can be obtained that go back in time for 2,000,000 years. Since the layers are preserved in the pipe in the order in which they were laid down, it is possible to examine the deposits with various techniques that tell of past climates and events. For example, a layer of glacial till would indicate an era of lower temperatures in the past, while pumice or ash would reveal volcanic activity. The tests of foraminifera can often be identified as predominantly cold-water or warm-water forms. Oxygen isotope analysis can be applied to the O^{18}/O^{16} ratio, which is a delicate "fossil thermometer." Providing information of this nature is but one of the many ways in which oceanography comes to the assistance of other sciences.

IV. PHYSICAL PROPERTIES OF SEA WATER

1. Salinity and Chlorinity.—All the principal salts in sea water are found everywhere in the same proportions, and only the total quantity of salt in a given amount of sea water varies significantly. It is therefore possible to express this relationship as the salinity. Salinity is defined as the weight of dissolved salt in 1,000 parts of sea water, *i.e.*, grams per kilogram, when all the carbonates and organic matter have been converted to oxides, and all bromides and iodides to chlorides. The value found in accordance with this definition is about one-half of 1% lower than the actual weight of dissolved solids. Because of the accuracy required in physical oceanography, it is necessary to report salinity to four significant figures, and, as the Scandinavian countries (where physical oceanography developed) use decimal currency, it has become customary to report salinity not as per cent (%) but per mille ($^0/_{00}$). By this convention, the four-digit numbers look like amounts of money, and printing and proofreading of long columns of figures are made easier. Thus salt content of the open ocean, which ranges from 3.2% to 3.6% salt, is expressed as salinity $32^0/_{00}$ to $36^0/_{00}$.

Seas receiving extensive river drainage may have lower values. The northern Bay of Bengal, Yellow sea and Okhotsk sea all have surface salinities as low as $30^0/_{00}$; the surface water of the Black sea is about $16^0/_{00}$; and the Baltic in the spring drops as low as $1^0/_{00}$. Where evaporation is high and river drainage and rainfall low, salinities as high as $40^0/_{00}$ are encountered in the Persian gulf and $41^0/_{00}$ in the Red sea.

It is not easy to make determinations of salinity directly, so that it is usually derived from measurements of some other property, such as electrical conductivity, specific gravity, index of refraction or chlorinity. The chlorinity of sea water is the value derived from direct titration of the halides with silver nitrate. Chlorinity was originally defined as the proportion (per mille) of halides in sea water if all the bromides and iodides were replaced by chlorides. The relationship between chlorinity and salinity was found in 1902 by Martin Knudsen and collaborators to be $S=0.03+1.805\times Cl$. Many years later, it was discovered that, mainly because of changes in values for atomic weights, chlorinity as defined by this expression (which formed the basis of Knudsen's tables) was 45 parts in 100,000 lower than the value given by the original definition, and J. P. Jacobsen and Knudsen in 1940 therefore redefined chlorinity as 0.3285233 of the silver equivalent of sea water.

The constant term 0.03 in the relationship between salinity and chlorinity is of interest, because it means that water having zero chlorinity still has a salinity of $0.03^0/_{00}$. This apparent paradox results from the fact that low salinities in the ocean generally result from mixing with river water rather than rain water. River waters usually contain significant quantities of dissolved salts, invariably with much more sulfate and bicarbonate than chloride, and hence their chloride values are zero while their total salt values are still significant.

2. Temperature, Freezing Point and Heat Capacity.—The freezing point of ordinary sea water (salinity $34.75^0/_{00}$) is 28.7° F. Temperatures in the ocean range upward from this value to maxima of a little above 85° F. in the open tropical seas and as high as 90° in the Persian gulf in summer.

The distribution of surface temperatures in the ocean is approximately as shown in Table III.

Below the surface, the ocean almost invariably shows a decrease of temperature with depth, reflecting the fact that colder water is denser and hence sinks below warmer water. Fig. 4 shows a typical distribution of temperature with depth in the ocean. Near the surface there is generally a layer of constant temperature resulting from mixing by the action of wind and waves. This mixed layer, or isothermal layer, has a thickness ranging from 10 ft. or less in calm regions to as much as 600 ft. in trade-wind latitudes. Below it is a zone of rapid temperature decrease, the thermocline, which merges smoothly with the temperature of the deep oceans. The ocean is everywhere colder than 60° F at a depth greater than 1,200 ft., and even at the equator the temperature in deep water is as low as 35°, since the water of the deep oceans has sunk from the surface in polar regions. The average temperature of the ocean was determined in 1957 by R. B. Montgomery and associates to be 39° F.

TABLE III.—*Approximate Distribution of Surface Temperatures*

Average surface temperature, ° F.	Percentage of area of ocean
35 or below	12 5
35 40	4 9
40 45	3.6
45 50	4.8
50 55	5.2
55 60	5 5
60 65	5 9
65 70	7.5
70 75	10 2
75 80	17.0
80 85	22.8
85-90	0.1

There is an important difference between temperatures in the sea and those encountered in deep wells or mine shafts on land. In sedimentary rock, there is a temperature increase of 1° F. for every 60 to 110 ft. of depth. In the sea, this geothermal gradient is almost entirely suppressed, and when it is encountered, in deep water basins separated by ridges from the general flow of bottom water (as in the Mediterranean sea), it amounts to only 1° F. in 10,000 ft. of depth.

The specific heat of sea water is reduced only slightly below that of distilled water by the dissolved salts and amounts to about 0.93 B.T.U. per pound. The significance of this figure is the comparison with the specific heat of air, 0.24 B.T.U. per pound, and of rock and soil, 0.19 to 0.22. Thus the total heat capacity of the

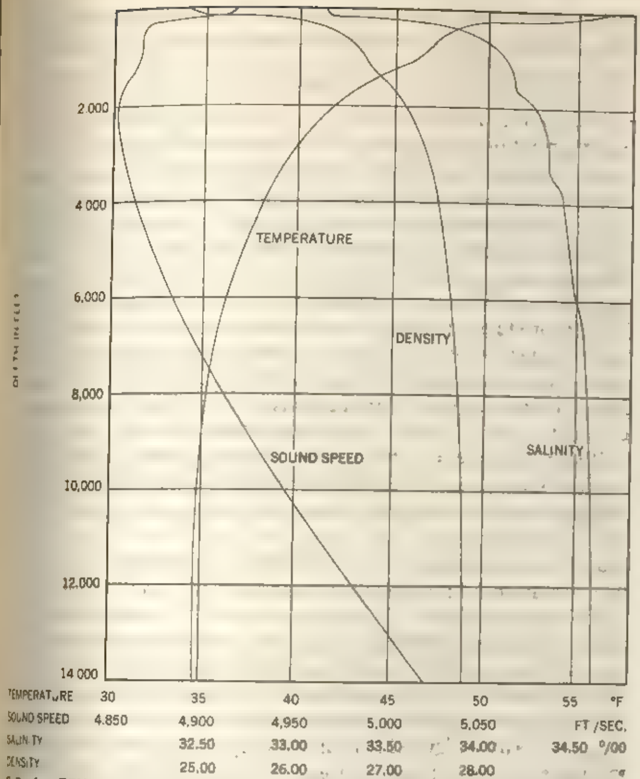

FIG. 4—TEMPERATURE, SALINITY (IN PARTS PER 1,000 BY WEIGHT), DENSITY (IN σ UNITS, EQUAL TO 1,000 × [SPECIFIC GRAVITY—1]) AND SOUND SPEED, SHOWING TYPICAL VARIATION WITH DEPTH IN THE PACIFIC OCEAN OFF SOUTHERN CALIFORNIA

lower 10,000 ft. of the atmosphere is matched by the top 2.7 ft. of the ocean, and the heat capacity of the top 100 ft. of the dry land, which is as deep as any annual heating or cooling effect is felt, is the same as the top 40 ft. of the sea. The annual variation of surface temperature in the sea has a maximum range of 15° F. at about latitude 40° N. in the Atlantic and 18° F. in the North Pacific. It amounts to only 3° or 4° F. in the tropics and 9° or 10° F. in the south temperate zones. Annual variations are felt to a maximum depth of about 600 ft., unless the water at the surface is cooled sufficiently to cause it to sink to the bottom. This condition takes place in the winter in the Arctic and Antarctic oceans and in the eastern Mediterranean sea. In the polar regions, formation of denser water at the surface is accelerated by ice formation, which by removing part of the water makes the remaining water saltier.

Fresh water has a maximum specific gravity at 39.2° F., which means that water cooled below this temperature cannot sink to the bottom of a lake until the entire lake has reached this temperature. The addition of salt to water, however, lowers the temperature of maximum specific gravity very rapidly, and at a salinity of 24.70$^0/_{00}$ this temperature is the same as the freezing point. At higher salinities, *i.e.*, everywhere in the open oceans, sea water always has a higher specific gravity the lower its temperature.

The main source of heat in the ocean is radiation from the sun, most of which is absorbed in the top five feet of water. Except under unusual conditions, however, such as in sheltered bays, mixing by waves and wind distributes this heat through a much greater depth. When the air is colder than the sea surface, this heat is given off again to the atmosphere. The ocean thus exerts an ameliorating effect on climate. Since the global circulation of air is from west to east in temperate and polar latitudes, this effect is felt much more on the western edges of continents. Ireland, in the same latitude as Labrador, has a much milder climate, and the Gulf stream, though it passes close to the coasts of North Carolina and Virginia, is virtually without influence on their climate or that of the rest of the United States.

3. Density and Pressure.—Sea water weighs almost exactly 64 lb. per cubic foot, so that 35 cu.ft. weigh a long or shipper's ton (2,240 lb.), a relationship widely used in naval architecture. Since the density of distilled water is 62.43 lb. per cubic foot, the specific gravity of sea water, in round figures, is 1.025. For the same reason as stated under salinity, it is customary to report the density of sea water in a unit equivalent to "grams per litre excess over one kilogram," designated by the symbol σ. In this notation, the specific gravity of 1.025 is expressed as σ of 25. Density increases with increasing salinity but decreases with increasing temperature. It also increases with increasing pressure, because of the slight but appreciable compressibility (about 4 parts in 100,000 per atmosphere pressure). Fig. 4 includes a typical curve of density as a function of depth. The pressure increases in the sea as depth increases, at the rate very nearly of one atmosphere for each 33 ft. Table IV gives the average pressure in the ocean as a function of depth.

TABLE IV.—*Average Pressure as a Function of Depth*

Depth in feet	Pressure in pounds per square inch
1,000	445
2,000	892
4,000	1,788
6,000	2,685
8,000	3,586
10,000	4,488
20,000	9,034
30,000	13,640
35,958	16,415

The values shown represent the pressure due to sea water alone, and for strict accuracy an additional 15 lb. per square inch should be added to include the atmospheric pressure in the total pressure at depth.

As an example of how pressure affects specific gravity, we can take the calculation of the mean density of sea water. The mean temperature of 39° F. and mean salinity of 34.75$^0/_{00}$ yield a specific gravity of 1.02762 or σ of 27.62 from Knudsen's tables. This value of σ is designated $\sigma_{t,0}$ to indicate that it is corrected for temperature but not for pressure. The mean depth of the ocean is 12,450 ft., and the pressure at this depth is 5,600 lb. per square inch. Application of compressibility, as given in LaFond's tables, yields $\sigma_{t,p}$ of 44.90 or specific gravity of 1.04490 for this pressure.

Multiplying 62.43 by 1.04490 gives 65.23 lb. per cubic foot as the average density of sea water in the ocean. Since the volume of the ocean is 3.288×10^8 cu.mi. and there are $5{,}280^3$ or 147,197,-952,000 cu.ft. in a cubic mile, the total weight of sea water in the ocean is $65.23 \times 3.288 \times 10^8 \times 1.472 \times 10^{11}$ or 3.16×10^{21} lb.

4. Electrical Conductivity.—Since sea water is a fairly strong salt solution, its electrical conductivity is much greater than that of pure water. The values of electrical resistance given in Table V are for sea water of salinity 34.75$^0/_{00}$.

TABLE V.—*Values of Electrical Resistance*

Item	At 39° F.	At 77° F.
Ohms per foot cube	1.01	0.69
Ohms per inch cube	12.1	8.3

5. Colour and Transparency.—The blue colour of sea water, like the blue of the sky, is the result of molecular scattering of light. Dissolved yellow pigments produced from the decay of plants give the green colour to coastal waters. Abundant phytoplankton and suspended sediments add a brownish tinge to estuarine waters.

In certain oceanic areas, such as the Sargasso sea, where phytoplankton is scarce, sea water is nearly as transparent as distilled water. Where phytoplankton is more abundant, the transparency is much less. The area near the surface to which sufficient light penetrates to enable phytoplankton to carry on photosynthesis is called the euphotic zone. Its thickness ranges from a maximum of over 300 ft. in the open sea to 3 ft. or less in estuaries.

6. Sound in the Sea.—The speed and other characteristics of sound in the ocean are of considerable practical importance. The reception of a reflected sound signal can be used to determine the depth to the bottom and to layers in the sub-bottom, and also to locate schools of fish or other submerged objects. Echo-location

systems, known in naval parlance as asdic or sonar, have been highly developed for detecting submerged submarines. (*See* SOUNDING; ECHO SOUNDER.)

In the operation of sonar, the refraction, scattering and absorption of sound are limiting factors. Refraction results from the variation in speed of sound, which causes bending of the sound rays. The speed of sound at one atmosphere pressure, salinity 34.75‰ and temperature 39° F. is 4,800 ft. per second, or about 4.5 times its speed in air. The speed increases with increasing pressure, temperature or salinity. In the thermocline, temperature decreases rapidly, but in the deeper layers it changes more slowly whereas pressure steadily increases; hence, sound speed commonly shows a minimum value at an intermediate depth, as in fig. 4. Horizontally directed sound waves tend to be refracted toward the zone of low sound speed, and thus they are trapped in the zone of minimum speed and may be transmitted for long distances with little loss in intensity.

This layer or channel is the basis of the system of sofar (*so*und *f*ixing *a*nd *r*anging), which has been proposed as a means of long-distance communication, particularly for the location of survivors at sea. An explosive charge set to detonate at the depth of the sound channel could be detected by hydrophones placed at the proper depth thousands of miles away, and the differences in time of the arriving signals could be used to construct hyperbolas that would intersect at the detonation point.

Much of the scattering of sound in the ocean results from echoes produced by living organisms, many of which migrate upward to the surface at night from a depth of about 1,000 ft. Absorption is due mainly to the content in sea water of dissolved magnesium sulfate, which has a specific ability to absorb sound, particularly at high frequencies.

V. MOVEMENT OF SEA WATER

1. Currents.—Motion of water particles in the sea is of various kinds. The molecular motion involved in the propagation of sound has been covered above. The periodic rise and fall of the surface is described in the articles TIDE; WAVES OF THE SEA. There remain to be considered the horizontal and vertical circulation of water masses in the sea. The horizontal movement of water is called a current. In the ocean there exist both tidal currents, or tidal streams, which are associated with the tidal rise and fall of sea level and result from the same causes, and nontidal currents. The nontidal currents show considerable regularity in their general flow, although they may be modified by a persistent wind that blows for several days in the same direction. However, in temperate and boreal latitudes changes in weather tend to occur too quickly for the ocean to respond to them, so that the nontidal currents in a given season of the year are relatively stable.

2. Coriolis Force.—In describing the motion of any particle on the rotating earth, it is necessary to consider the rotation of the earth. To an observer in space, the motion would not appear the same as to an observer also on the rotating earth. Since a body once set in motion continues that motion relative to space, it has an apparent deflection relative to the observer on the rotating earth. The horizontal component of this deflection is proportional to the sine of the latitude, and thus it is a maximum at the poles and zero at the equator, and the direction in which this apparent deflection is exerted is opposite on opposite sides of the equator.

This deflecting force is called Coriolis force, after the French engineer who first derived it mathematically in 1835. Coriolis force actually affects all motion on the earth's surface, but usually it is slight in comparison with the other forces of friction and propulsion. In the cases where a motion once initiated is proceeding against almost negligible friction, however, it must be considered. These cases include a projectile or missile in flight, a swinging pendulum (Foucault's pendulum), a moving air mass (*see also* BUYS BALLOT'S LAW) and an ocean current.

The direction of Coriolis force is to the right (clockwise) in the northern hemisphere and to the left (counterclockwise) in the southern. Since this is the apparent direction in which the sun moves, it is convenient to describe it as *cum sole* ("with the sun"). If no other force acts on a body moving with speed v, it will be directed *cum sole* in a circle (the inertia circle), the radius r of which is given by the centrifugal force $\frac{V^2}{r}$. This will equal the Coriolis force, $2\omega v \sin\phi$, where ω is the angular velocity of the earth's rotation ($.729 + 10^{-4}$ radians/second) and ϕ is the latitude. In latitude 40°, this relationship yields a radius of 3 mi for a speed of 1 m.p.h. Obviously, therefore, ocean currents that flow in the same direction for thousands of miles at speeds of this order of magnitude cannot persist unless a force is provided to oppose Coriolis force. Just as in the atmosphere, this opposing force is supplied by the pressure gradient. In the sea, pressure is given by the product of gravity × depth × density. Gravity is of course constant at any point, so for a given depth the pressure can be varied only by varying the density. Thus if a permanent steady ocean current is found to exist, there will be found a density gradient across it, with the lightest water *cum sole*.

Water movement in the inertia circle has been observed in the tideless Baltic sea, under conditions where there were no density gradients in the water, but, in general, motion of this kind is unusual in the sea.

3. Tidal Streams and Estuaries.—In restricted channels, a tidal stream exhibits a regular pattern of ebb (seaward flow) and flood (landward flow). The duration of each corresponds generally to the time interval between high water and low water, but in the case of river mouths, the ebb is usually longer or faster than the flood, in order to accommodate the river flow. In such a river mouth, there is generally an upstream undercurrent of sea water, forming a salt wedge, which thins out upstream with a fairly sharp interface between the salt water and the fresh water above. Mixing takes place all along this interface, and the salt water returns to the sea mixed with the river water in the upper layers.

The water discharged to the sea by a river is fresher and therefore lower in density than the sea water, hence it tends to turn *cum sole* along the coast. Thus, along the Atlantic coast of the United States, which has numerous rivers producing an appreciable lowering of the coastal salinity, the general inshore current sets to the south as far as Cape Hatteras. On the coast of California, where rainfall and runoff of the coastal rivers is confined chiefly to the winter months, the California current sets south in the summer, but in winter a well-defined north-setting inshore current, the Davidson current, makes its appearance.

The Amazon river is unique among the great rivers of the world in that its mouth is exactly on the equator, where Coriolis force is zero. Since there the fresh water has no tendency to be deflected either right or left, instead of hugging the coast it spreads out in a thin layer to seaward, so that the fresh waters of the Amazon can be detected for scores of miles off its mouth.

Tidal currents exist in the open sea as well as in restricted channels, since they represent the motion of the water particles in the progressive or standing waves that comprise the tide. In deep water their effect is small and almost immeasurable, but on the continental shelves they are usually the predominant current. When not confined by coastal barriers, tidal currents generally change direction continually *cum sole*, and where the tide is mainly semidiurnal in character a drifting object completes a roughly circular path every 12 hours. A typical diameter for such a circle is 4 or 5 mi., but appropriate hydrographic publications, *e.g.*, the U.S. coast and geodetic survey *Current Tables* for United States waters, should be consulted for specific details at a given locality.

4. Wind-Driven Currents.—Whenever the wind blows over a stretch of water for an appreciable time, the frictional drag between wind and water and between the layers of water will set the water in motion. V. W. Ekman showed in 1902, as the result of observations of the drift of pack ice made by Fridtjof Nansen in the "Fram," that in water of sufficient depth, assuming that the water is homogeneous and that eddy viscosity does not vary with depth, the surface wind current is directed 45° *cum sole* from the wind direction. Each layer below the surface is deflected further *cum sole* by the layer above, but with a lower speed so that the water on the average is carried 90° *cum sole*. There even exists a depth (equal to $7.6W\sqrt{csc\ \phi}$ where W is wind speed in

feet per second) at which the current initiated by the wind flows in the direction opposite to the wind, although its speed is only $\frac{1}{23}$ that of the surface current. The speed of the wind-driven current at the surface is $.013W\sqrt{\csc\phi}$. It is obvious that these relationships cannot be valid near the equator.

5. **Permanent Currents.**—Fig. 5 presents the system of permanent surface currents in the ocean. Comparison with a chart of average prevailing winds shows in general good agreement with the principle that the water moves about 45° *cum sole* from the wind, but there are two notable individualities that result from other causes. The well-developed countercurrents that flow eastward just north of the equator in the Pacific and Atlantic and just south of it in the Indian ocean do not appear to agree with what would be expected from prevailing winds. However, H. U. Sverdrup in 1947 showed that the equatorial countercurrents develop in the region of minimum wind stress and can be derived from a knowledge of wind stress alone.

The intense currents that develop on the western sides of the oceans, such as the Kuroshio in the North Pacific, the Gulf stream in the North Atlantic and the Agulhas current in the Indian ocean, likewise are not related to the local winds. Henry Stommel between 1948 and 1951 showed that this westward intensification of surface currents results from the variation of Coriolis force with latitude, and that, although the winds add energy to the current system of each ocean over the whole ocean, this energy is dissipated mainly in the strong western current. W. S. von Arx confirmed this finding by model experiments in 1952. G. Neumann in 1955 accounted for the lack of such a pronounced western current in the South Atlantic by showing that there the change in Coriolis force with latitude is nearly offset by a corresponding change in the depth of the current system.

Fig. 5 clearly justifies the division of the ocean into seven main oceans. Each ocean has its own virtually closed surface circulation, that of the Antarctic being to the eastward around Antarctica and that of the Arctic (not shown) entering from the Atlantic in the Barents sea, proceeding northeastward, circling the pole and leaving down the east coast of Greenland. In comparison, the exchange with the Pacific through Bering strait is much less important, though Martin Johnson has shown from study of the zooplankton that appreciable quantities of water reach the Arctic coast of Alaska from the Bering sea. It is particularly noteworthy that in the surface circulation of the ocean very little water crosses the equator, except where the South Equatorial current impinges on the bulge of South America. This flow makes up for the water that sinks below the surface in the northern North Atlantic in winter and crosses the equator near the bottom.

6. **Measurement of Currents.**—Numerous means, direct and indirect, have been developed for measuring ocean currents. If the navigator of a ship keeps careful records of his course and speed, the difference between the position so given (the dead reckoning) and the position actually fixed by astronomical or electronic means can be attributed to the effect of current. Hundreds of ships report daily observations of this sort to the world's hydrographic offices, and although the results of necessity average the current over fairly large distances, sufficient observations are available to permit averaging out of all random errors. These results form the basis of generalized current maps of large areas, such as fig. 5. A somewhat similar method involves the dropping of bottles or cards (bottle post or drift cards) at known positions and noting the position of recovery. This method is excellent when practical applications are desired, such as the fate of sewage or oil disposed of at sea or the drift of fish eggs, but it tells very little about the actual path of the currents between the points of release and recovery.

An elaboration of the drift bottle is a drogue, or other object, which will be acted on by the current at a predetermined depth and will tow a light or radar reflector floating on the surface. Such a drogue can be followed from a boat for days or weeks and its successive positions determined. A further refinement, developed by J. C. Swallow in 1955, is to provide the float with a simple sound-generating apparatus, leaving it independent of any connection with the surface, and to follow its course by listening with directional hydrophones. This method has provided information on currents as deep as 5,000 ft.

Surface currents are readily determined from anchored ships by the same methods as those used to find a ship's speed through the water. Numerous observations of tidal currents have been made in this way from lightships. The Ekman meter, used for subsurface currents from an anchored ship, is essentially a propeller steered into the current by a vane. Mechanisms are fitted for stopping and starting at predetermined times, and counting dials read the number of turns of the propeller in the elapsed time.

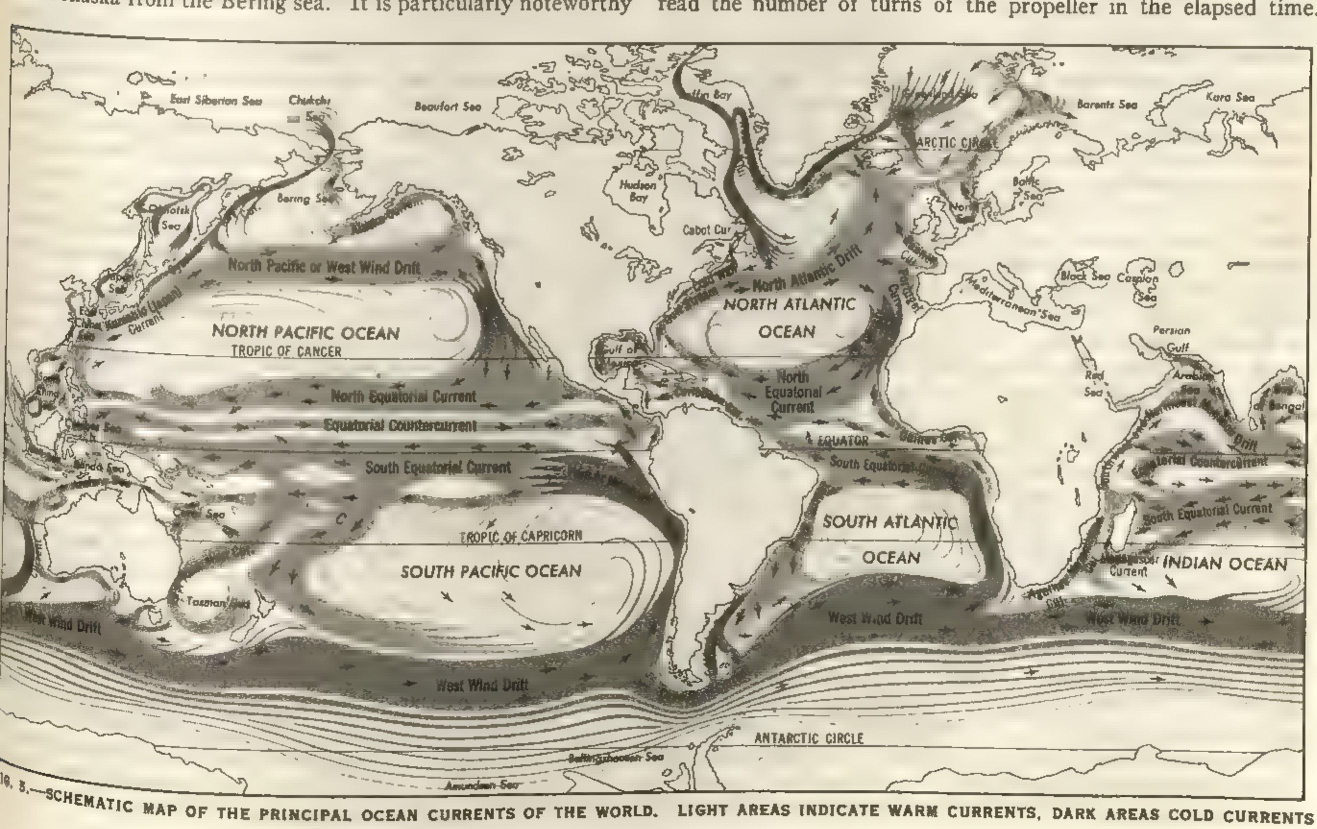

FIG. 5.—SCHEMATIC MAP OF THE PRINCIPAL OCEAN CURRENTS OF THE WORLD. LIGHT AREAS INDICATE WARM CURRENTS, DARK AREAS COLD CURRENTS

Lead or bronze pellets drop at intervals into a compartmented compass box to show the current direction. The Roberts meter is somewhat similar in principle, but transmits its readings electrically or by radio from a buoy at the surface. There have been many other developments along similar lines, but the principal drawback with such devices is the difficulty of anchoring a ship in deep water.

A method developed in 1948 by Von Arx is to make use of the electrical properties of sea water itself. Since sea water is an electrical conductor, any motion it makes in the earth's magnetic field will set up an electrical current. A pair of electrodes in tandem, towed behind a ship, will record an electrical signal proportional to the component of the ocean current normal to the ship's course. A 90° change in course, therefore, will provide both components of the ocean current. The geomagnetic electrokinetograph, or GEK, thus has no problems of anchoring in deep water; in shallow water the electrical conductivity of the bottom needs to be considered. Joseph L. Reid, Jr., in 1952 showed that the observed drift of a drogue at 30 or 60 ft. among the islands off southern California agreed excellently with the integrated currents obtained simultaneously with the GEK.

A variation on the same principle is to use fluctuations in electrical current recorded in a submarine cable. This method has been employed in the English channel and in the Straits of Florida to measure the total current transport through the strait, and excellent agreement with flow deduced from tide, sea level and winds has been obtained in the Straits of Dover with this method by K. F. Bowden.

The geomagnetic methods, drogues and meters all give the total resultant water movement at any point, inertial, tidal and wind driven as well as permanent. By determining accurately the density of the water at a number of points, it is possible to compute the permanent currents, since, as shown above, the density gradient is matched by Coriolis force. In practice this is done by stopping a ship at intervals of about 60 mi. and lowering sampling bottles equipped with recording thermometers to a number of depths. Commonly 15 or more samples are taken to depths of down to 4,000 ft. or more, the samples being only 30 ft. apart near the surface but at greater intervals as the depth increases. The temperature is read at each depth to .03° or .04° F.; the salinity of the water sample is determined to $.02^{0}/_{00}$, and from these the density or specific gravity is calculated to .01 in σ_t. Each vertical series of samples constitutes an oceanographic station, and at each station the average density is computed for the vertical water column by an ingenious series of approximations. Since pressure is the product of density × gravity × depth, the height of the water column above levels of identical pressure at two adjacent stations will vary inversely with the mean densities, and the difference in height is equivalent to a difference in sea level between the two stations. On a nonrotating earth, the water would flow like a river, downhill from the higher level to the lower; but since on the rotating earth the density gradient is assumed to be balanced by Coriolis force, the motion must be directed not down the slope but 90° *cum sole*. The downslope acceleration, slope × gravity, thus equals $2\omega v \sin\phi$, or $v = \text{slope} \times \text{gravity}/2\omega \sin\phi$. At latitude 45°, for two stations 100 mi. apart, if the difference in sea level (or dynamic height) is one foot, the slope is 1/528,000 or 1.89×10^{-6}; gravity is 21.94 mi. per hour per second; and $2\omega \sin\phi$ is $2 \times .729 \times 10^{-4} \times .707$ or 1.03×10^{-4} radians per second. Hence the current speed is

$$\frac{21.94 \times 1.89 \times 10^{-6}}{1.03 \times 10^{-4}} = .40 \text{ m.p.h.}$$

In regions like the Gulf stream, where speeds of 4 m.p.h. are often observed, the sea level therefore changes about one foot in ten miles. In practice, a map of the sea surface is prepared, much like a weather map, on which contours of equal dynamic height are drawn. The current direction is along the contours, and its speed is inversely proportional to the spacing of the contours.

This geostrophic, *i.e.*, earth's rotation, method, of course, is not valid near the equator, where Coriolis force vanishes in respect to horizontal movement. Its main drawback elsewhere is its dependence on locating a level of no motion above which the densities are averaged. But the validity of the assumption that friction can be neglected and hence the details of computed current flow will agree with those observed by other methods has been repeatedly demonstrated: in the Gulf stream by Georg Wüst in 1924 comparing direct current measurements from an anchored ship; on the Grand Banks by the International Ice patrol, comparing observed drifts of icebergs; and in many other cases. The geostrophic method is also of less use in very deep water, since there the variations in density are not much greater than the uncertainties in their measurement.

7. Subsurface Currents.—In general, in the upper layers of the sea, the geostrophic method can be employed to determine currents below the surface as well as at the surface itself. It has shown that the California current extends to a depth of less than 1,500 ft., the Kuroshio and Gulf stream to 3,000 or even 5,000 ft., and the West Wind Drift in the Antarctic to 10,000 ft. In certain areas the currents at depth are opposite to those at the surface. Thus, Wüst in 1955 computed that at a depth of 10,000 ft. along the Atlantic coast of South America there are currents setting southerly with speeds up to 0.28 m.p.h., while near the bottom, in depths of 11,500 ft. or more, there are currents setting in the opposite direction with speeds as high as 0.35 m.p.h. Stommel in 1956 showed that similar currents should exist beneath the Gulf stream, and such southerly setting currents at depths of 8,200 to 9,200 ft., with speeds up to 0.2 or 0.3 m.p.h. were observed there using Swallow floats from the R.R.S. "Discovery II" in 1957. Photographs of the ocean bottom confirm the existence of strong currents at great depths, as they frequently show the presence of ripple marks.

A subsurface current of a much different character was demonstrated by Townsend Cromwell in 1952 on the equator in the central Pacific. The surface current, the Equatorial current, set west at about 1 m.p.h., while drogues placed at a depth of only 200 ft. revealed the existence of a narrow current (which has been named the Cromwell current) setting at an even greater speed in the opposite direction. R. Montgomery subsequently called attention to records of a similar undercurrent in the Atlantic, and J. Knauss observed an equatorial undercurrent in the Indian ocean in 1963.

8. Density Currents.—Certain permanent currents in the ocean are unrelated to the general wind-driven circulation that has just been considered. For example, in the Straits of Gibraltar there is a strong surface current (up to 4 m.p.h.) entering the straits above an equally strong subsurface current flowing in the opposite direction. This circulation results from evaporation in the Mediterranean, which produces water of high salinity that sinks below the surface in the winter months. Although the net evaporation from the Mediterranean amounts to only 1.5 cu.mi. per day it sets up an exchange of about 25 times as much water, so that the inflow through the straits is 36.3 cu.mi. per day and the subsurface outflow 34.8. This influx of water is equivalent to the total volume of the Mediterranean every 75 years.

9. Turbidity Currents.—Another type of transport in the sea completely unrelated to the kinds of current previously described is the turbidity current. This type of flow is thought to take place chiefly down the continental slopes, where loose mixtures of sediments and water collect. From time to time, it is believed, these collections of material dislodge, often under the impetus of earthquakes, and the turbulent mixture of sediments and water, with an average density much greater than water but with many of the properties of a fluid, cascades down the slope like an avalanche. For many years the existence of such currents was accepted only by geologists, on the basis of small-scale laboratory experiments and of the observed characteristics of marine sediments, sedimentary rock and submarine canyons, which are otherwise very difficult to explain. Bruce C. Heezen and Maurice Ewing in 1952, however, presented information from the timing of breaks of transatlantic telegraph cables after an earthquake near the Grand Banks in 1929 which showed that a disturbance had proceeded down the continental slope at a rate up to 60 m.p.h., and they subsequently demonstrated that the basin at the foot of the slope was covered with freshly deposited sediment of shallow-water origin. Al-

though this report was by no means universally accepted at the time as proof of the existence of such turbidity currents, an earthquake at Orléansville, Alg., in 1954 broke cables in a similar fashion, yielding a downslope speed up to 45 m.p.h.

10. Vertical Water Movements.—When a persistent wind blows along a coast that lies to the left of the wind direction (in the northern hemisphere) the net transport of water in the wind-induced current is offshore. Since the coast acts as a barrier, water to replace that blown offshore can only come from the deeper layers. This phenomenon is known as upwelling, and it exists along the coast of northern California in summer and off Morocco, Peru and South-West Africa. The replacement water comes from a depth of 600 to 1,000 ft., that is, from well down the thermocline and below the euphotic zone, so that the water is both appreciably colder and richer in plant nutrients than the water it replaces. Zones of upwelling, therefore, considerably modify the climate of the coasts where they occur (the coastal fogs of California result from this cause, for example). They are also productive fishing areas.

TABLE VI.—*Abundance of Elements in Sea Salt*
(in parts per 1,000,000 parts of sea water by weight)

Element	Average concentration	Remarks	Element	Average concentration	Remarks
Hydrogen	2.7	(also in water) major constituent	Silver	.0003	...

In the open sea, areas of similar upward water movement are found in regions of divergence—lines along which the currents tend to flow away on both sides. Again the continuity is maintained by water that rises to the surface. Generally the vertical movement is less than 1,000 ft., as along the Pacific equator and the northern boundary of the Equatorial countercurrent, but in the Antarctic, particularly south of the Atlantic, deep water rises to the surface.

Convergences are lines toward which currents flow from both sides and where water, therefore, must be sinking. The water sinks only to the depth where water of corresponding density is found, which in most regions is not far below the surface, and there it spreads out sideways. The bottom water of the Mediterranean, however, is renewed by surface water that sinks in winter along its northern coasts; the Arctic ocean is filled with water that has been cooled in the Norwegian sea; the deep water of the North Atlantic is renewed from the surface just to the south of Greenland; and the rest of the ocean derives its bottom water mainly from the Antarctic, where the densest water is formed in winter along the continental shelf, particularly in the Weddell sea. Lines of convergence exist all around Antarctica (the Antarctic convergence), as well as in the subtropics, the tropics, the Equatorial current system and the North Pacific.

VI. CHEMISTRY OF SEA WATER

1. Elements in the Sea Salts.—About 60 of the first 92 elements in the periodic table have been detected in sea water. They exist mainly as dissolved salts, although some are dissolved gases, some are mainly in particulate form, and hydrogen and oxygen of course make up the water itself. In each 1,000 parts by weight of sea water, on the average, there are 965.1 parts of water and 34.9 of salt. The water is composed of 108 parts of hydrogen and 857.1 parts of oxygen, in addition to which 1.9 parts of oxygen and a trace of hydrogen are in chemical combination in the salts, mainly with the sulfur, carbon and boron. There is also a significant quantity of oxygen present as dissolved gas (*see* Table VI).

Although no sharp line can be drawn, it is possible to distinguish between the major constituents and the minor constituents in the salt. The major constituents consist of the cations of sodium, potassium, magnesium, calcium and strontium and the anions of sulfate, chloride, bromide, fluoride, carbonic acid and boric acid. They are found everywhere in the ocean in virtually the same proportions and make up 99.997% of the total dissolved salts. The minor constituents are all the rest of the elements. They in turn can be separated into conservative and nonconservative elements. The conservative elements, like the major constituents, are found everywhere in constant proportion to the total salts. The nonconservative elements show a variation in their relative concentration, principally through being selectively removed from the water by plants and animals. Table VI lists the elements in order of atomic number and gives their average concentration in sea water as far as they have been determined.

2. The Plant Nutrients in the Sea.—In agriculture, the main plant nutrients with which the farmer concerns himself are nitrogen, phosphorus, potassium and, to a lesser extent, calcium and magnesium. In the sea, as Table VI shows, potassium, magnesium and calcium are so abundant relative to the other necessary elements that they can be ignored as limiting factors in growth of plants. However, a new element, silicon, makes its appearance in the sea as a plant nutrient, since it is required by diatoms in the formation of the tiny shells (frustules) of silica with which they surround themselves. Although silicon is one of the most abundant elements in the earth's crust, the extremely low solubility of its compounds limits its availability in sea water. The main plant nutrients in the sea therefore are phosphorus, nitrogen and silicon.

All three of these elements are characteristically in short supply in the surface layers of the ocean, in the depths where sunlight is adequate for photosynthesis. Below this depth, they undergo rapid increases in concentration resulting from the redissolving of their compounds from the organic detritus sinking from above,

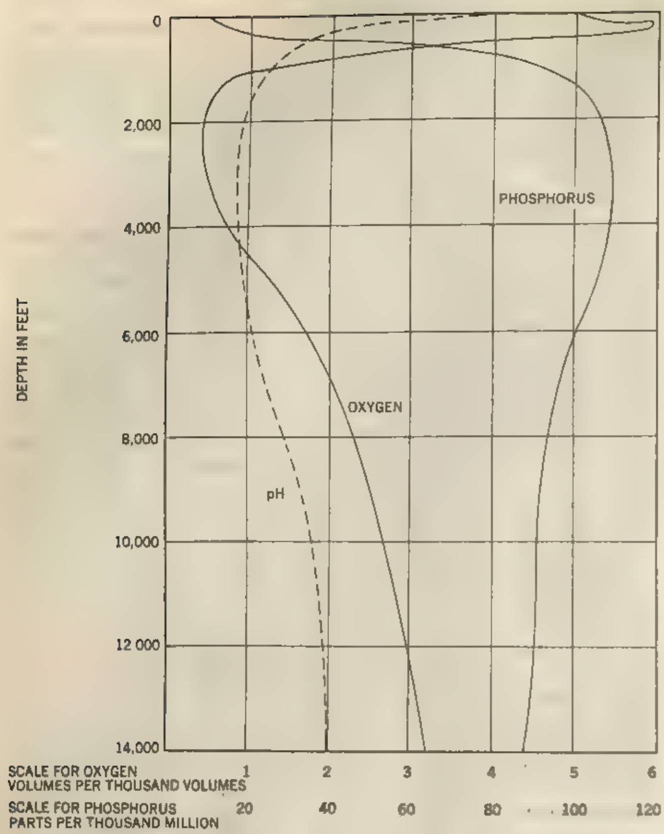

FIG. 6.—DISSOLVED OXYGEN, pH, AND DISSOLVED INORGANIC PHOSPHORUS, SHOWING TYPICAL VARIATION WITH DEPTH IN THE PACIFIC OCEAN OFF SOUTHERN CALIFORNIA

Multiplying the phosphorus values by 6.5 would furnish a good approximation to the curve for nitrogen (in nitrate)

or from the metabolism of the bacteria and animals living in the deeper water. Phosphorus occurs in the sea chiefly as dissolved phosphate, although there are also significant quantities of organic phosphate compounds dissolved in the waters near the surface. Fig. 6 shows the typical distribution of phosphate with depth in the North Pacific. The association of a maximum in the phosphate curve with a minimum in the oxygen curve is characteristic of all the oceans.

There is less phosphate in the waters of the Atlantic, a typical curve for that ocean increasing from zero at the surface to 60 parts of phosphorus per 1,000,000,000 parts of sea water (by weight) at 3,000 ft. depth and decreasing again to about 45 at 6,000 ft. Occurrence in the Indian ocean is intermediate between the Atlantic and Pacific.

Like phosphorus, nitrogen occurs to some extent in dissolved organic compounds in the sea, but their distribution is not well known. Most of the dissolved nitrogen in the sea is in the form of nitrate. The distribution of nitrate with depth is very similar to that of phosphate, and all the statements in the preceding paragraph and in fig. 6 about phosphate will be equally true for nitrogen, if the values for phosphorus are multiplied by 6.5. Ammonia also occurs to some extent in the sea, as the first step in the decomposition of organic matter, either by bacteria or metabolically. In the illuminated layers it is utilized by plants as readily as nitrate, and in the deeper layers it is oxidized by bacteria, first to nitrite and then to nitrate.

Silicon occurs both in solution, as silicate, and in particulate matter, as clay or undissolved fragments of diatoms. The same kind of increase of silicate with depth is observed as with nitrate and phosphate, typical values ranging from 300 parts of silicon per 1,000,000,000 at the surface to 5,000 at a depth of 6,000 ft. in the Pacific and from 50 at the surface to 1,000 at 6,000 ft. in the Atlantic. Since silicon is not needed by bacteria in their metabolism, its regeneration in the water must be entirely from physical solution of the silica in diatoms, and hence maxima do not occur in association with oxygen minima.

In comparison with the total amount in the sea, very little phosphate or nitrate enters the sea from rivers. Silica, however, is delivered to the ocean in abundance from the weathering of rocks. Thus there is usually enough silicate in the upper layers of the sea to support diatom growth after the nitrate and phosphate are used up, and silicate therefore is less often a limiting factor in plant growth than phosphate or nitrate.

3. Trace Elements.—Although most of the elements present in sea water are in quantities that the chemist would designate as traces, this term refers specifically to certain elements that are needed to support plant and animal life, but in quantities much smaller than those of the carbon, oxygen, hydrogen, nitrogen, calcium, phosphorus, silicon, sulfur, sodium, potassium and chlorine that make up 99.9% of the weight of living organisms. They are not needed for general tissue building or skeletal formation, but enter into specific compounds that serve such purposes as catalysts in respiration. Examples are magnesium in the chlorophyll molecule, iron in hemoglobin, copper in the hemocyanin of crustaceans, iodine in thyroxin or di-iodo-tyrosine in seaweeds and fluorine in teeth enamel. Other elements that are known to be required in the nutrition of plants are boron, zinc, molybdenum, cobalt and manganese.

Vanadium is accumulated by certain holothurians and tunicates (niobium may replace vanadium in one species of tunicate); bromine is incorporated into organic compounds in some corals and marine snails; and other marine organisms concentrate arsenic and nickel. Of these elements, cobalt and nickel are the least abundant in sea water, but there is no evidence to show that this low concentration limits plant growth. Iron and manganese, however, which are only slightly more abundant, very likely do limit growth in the sea, since their compounds are present in sea water mainly in particulate form and must be supplied largely by erosion or drainage from the continents. The other trace elements are for the most part sufficiently abundant in the ocean to take care of the requirements of most marine organisms. The vanadium-rich holothurians and tunicates are an exception. Their blood contains up to 10% vanadium, which is 50,000,000 times as much as there is in sea water. The requirement for collection and concentration of these trace elements is probably the main factor controlling the growth and abundance of these animals, although the role played by vanadium (or niobium) in their metabolism is not yet understood.

4. Dissolved Gases.—Besides the dissolved salts, sea water contains appreciable concentrations of dissolved gases. The exact amounts depend on the previous history of the water. The values given in Table VII represent saturation of the gases in equilibrium

TABLE VII.—*Saturation of Gases*
(solubility in volume of gas per 000 volume of sea water [ml./l.])

Gas	At 39° F.	At 77° F
Helium	.00004	.00004
Nitrogen	13.0	8.9
Oxygen	7.2	4.8
Carbon dioxide	.38	.20
Neon	.00018	.00014
Argon	.36	.23
Krypton	.00007	.00005
Xenon	.00002	.00001

with the atmosphere at the standard pressure of one atmosphere and the stated temperatures. In addition radon, which is radioactive with a half life of about four days, has been detected in sea water to the extent of about 3×10^{-12} millilitres per litre (ml./l.). Because of its short half life, it is not in equilibrium with the atmosphere.

Dissolved nitrogen is the most abundant gas in the ocean, as it is in the air. Although both nitrate-fixing bacteria and denitrifying bacteria have been identified in bottom mud, it appears that they lack sufficient nitrate and other food sources to operate to any significant extent in the sea. The dissolved nitrogen in sea water therefore shows little fluctuation and always corresponds closely to equilibrium with the atmosphere at the temperature and salinity of the water sample.

Dissolved oxygen, on the other hand, shows great variations in the ocean. Where photosynthesis takes place in the upper, illuminated layers of the ocean, oxygen values may exceed 120% of saturation. On the other hand, where biological oxidation is taking place in the absence of photosynthesis or renewal from the surface, the oxygen will be depleted. The distribution of dissolved oxygen with depth thus characteristically shows a marked decrease below the illuminated layers, with the curve going through a minimum and then increasing again with depth as in fig. 6. In the Atlantic, the values at great depth are often higher than at the surface, but in the North Pacific the increase is not so great. This difference in the oxygen content at depth reflects the different sources of supply of the deep water, which in the Atlantic is renewed by sinking from the surface both in the Arctic and the Antarctic, whereas the Pacific is cut off from the Arctic basin by Bering strait and can be renewed only from the south. Fig. 2, a plot of oxygen values at 13,000-ft. depth, well illustrates this difference. The oxygen values for the North Pacific (at the bottom of the figure) are below 3.5 ml./l., whereas at the same latitude and depth in the North Atlantic, the values are 5.0 to 6.0.

Under special conditions, oxygen depletion in the sea can be carried to the point where all the dissolved oxygen is used up. This effect occurs when the supply of decaying organic material sinking from above exceeds the supply of oxygen. Under such conditions, sulfate-reducing bacteria multiply, obtaining their oxygen requirement from the abundant sulfate ions in sea water and producing hydrogen sulfide. This gas is poisonous to practically all other forms of life in the sea. In the presence of oxygen it is quickly oxidized to sulfate and water.

The figures in Table VII for the solubility of carbon dioxide refer only to the amount in true physical solution. It will be observed that carbon dioxide is relatively much more soluble in water than the other gases, as it makes up nearly 2% of the gases in equilibrium with the atmosphere, in which it amounts to only .03%. Besides this great physical solubility, carbon dioxide is also in chemical combination in the dissolved salts, principally in the form of bicarbonate ion. In general, for each molecule of oxygen that is used up in respiration or oxidation, one molecule of carbon dioxide is produced, so that the curve for carbon dioxide as a function of depth should be a mirror image of the curve for oxygen. At great depths, however, the total carbon dioxide continues to increase, as the result of the redissolving of calcium carbonate particles which slowly sink through the depths from the photosynthetic zone where they were formed as mollusk shells, foraminifera tests and the like.

The high solubility of carbon dioxide in the sea is of great importance in understanding long-range changes of climate. Carbon dioxide in the atmosphere acts much like the glass in a greenhouse, passing the shorter radiation received from the sun but trapping the longer infrared radiation that originates on the earth's surface. Doubling the carbon dioxide content of the atmosphere would increase the surface temperature of the earth by 6½° F. Until the 20th century, the atmosphere and the ocean were in a steady state with regard to carbon dioxide, with precipitation of calcium carbonate in marine sediments proceeding about as fast as production of carbon dioxide by volcanoes. However, the great expansion in combustion of coal, oil and natural gas since about 1900 is supplying carbon dioxide from these "fossil fuels" at a rate estimated to provide a 30% increase in atmospheric carbon dioxide in a century. There is about 60 times as much carbon dioxide in the sea as in the atmosphere, but the rate at which the sea comes to equilibrium with the atmosphere is unknown. One of the principal problems investigated during the International Geophysical Year in 1957–58, therefore, was the distribution of carbon dioxide between the surface layers of the sea and the atmosphere, in order to determine how rapidly the sea will absorb the extra atmospheric carbon dioxide.

Helium, neon, argon, krypton and xenon belong to the family of "noble gases," which are chemically inert and are thus without significance in the sea. The atmosphere also contains traces of hydrogen gas, but there is no information as to whether the sea is in equilibrium with the atmosphere with regard to dissolved hydrogen. Methane and perhaps other hydrocarbon gases are known to be produced during the decomposition of organic matter, but their distribution in the sea has never been investigated.

5. Direct Production of Chemicals From Sea Water.—By appropriate chemical treatment, certain elements can be extracted directly from sea water without preliminary concentration. Thus, sea water is first acidified and then chlorinated to liberate bromine, which is extracted by blowing it out of the water with a current of air. The recovered bromine in turn is used to make ethylene dibromide, a constituent of ethyl gasoline.

Similarly, magnesium hydroxide is precipitated from sea water when the water is made alkaline. The alkali commonly used is calcium hydroxide, made by calcining oyster shells. The precipitate of magnesium hydroxide is filtered from the sea water. It is used directly as milk of magnesia, calcined to magnesia (MgO), converted to magnesium carbonate or treated with hydrochloric acid to produce magnesium chloride, which in turn, through electrolysis of the molten salt, is the basis for production of metallic magnesium. For the recovery of salts from sea water by evaporation, *see* SALT.

6. Gold From Sea Water.—Much popular interest has been aroused by the reported analyses of sea water for gold, silver and uranium. The hypothetical value of these substances in a cubic mile of the ocean is impressive. However, to obtain one troy ounce of gold from the sea (assuming 100% recovery) would require the processing of 8,000,000 tons of sea water and involve the separation of the gold from 280,000 tons of salts. Although 80 oz. of silver and 50 lb. of uranium would theoretically also be obtainable, it appears entirely impractical to obtain precious metals on a commercial basis. *See* also GEOCHEMISTRY.

VII. BIOLOGICAL OCEANOGRAPHY

It is virtually impossible to draw a firm line of division between marine biology (*q.v.*) and biological oceanography. However, we can include under biological oceanography the interrelationship between the plants and animals of the sea and its waters, currents and sediments, and consider marine biology as being concerned primarily with the form, functions and life histories of the organisms themselves. Many of the interactions between organisms and the chemistry of sea water and between organisms and the bottom sediments have already been covered.

1. Organisms and the Physical Properties of Sea Water.—Excepting the plants and animals of the intertidal zones, those that live in the sea are surrounded by an abundance of water at all times, and hence they do not develop the special tissues and organs for conserving water that are found in land forms. Likewise, the giant seaweeds have no need for the complicated vascular structure of trees, and their "roots" are simply devices for anchoring (holdfasts), not for collecting water. The buoyant support offered by water permits the development of such creatures as jellyfish, which entirely lack any skeletal structure and in fact are 96% sea water and 4% protoplasm (which itself is five-sixths water). Likewise, the organic matter in diatoms consists of about 6% chlorophyll, whereas the green leaves of land plants are only about 0.8% chlorophyll, since the large majority of the plant cells have to serve other functions than photosynthesis. Whales grow to a length of 100 ft. and a weight of over 100 tons; yet in the water they are swift and agile. A land-dwelling quadruped of like dimensions would have hopelessly overloaded limbs.

From the standpoint of temperature, the sea is a much more comfortable environment than the land. The total annual range of temperature, which may amount to 100° F. or even 125° F. on land, does not exceed 15° F. in the ocean, and the elaborate leaf-shedding that most land plants undergo in the temperate zones in order to minimize storm and ice damage in the winter is unknown in the marine environment. As long as light is available, marine plants thrive, whatever the temperature, and ice floes often are stained on their undersides by proliferating layers of diatoms. The open sea, however, lacks the firm support that terrestrial creatures derive from land, and therefore the drifting organisms of the sea (plankton) generally are equipped with some mechanism that keeps them from sinking to the depths. Thus, most diatoms,

which are single-celled algae with a siliceous covering that has a greater density than sea water, are shaped to provide the maximum drag, so that they will sink as slowly as possible. Dinoflagellates, chlorophyll-containing protozoa which are second only to the diatoms as primary producers of organic matter in the sea, have similar adaptive structures and are also equipped with a pair of oarlike flagellums with which they are to a limited extent self-propulsive.

The acoustic properties of water are utilized by only a few marine organisms. Numerous kinds of fish are known to make drumming or grunting noises, for purposes not entirely clear; porpoises and other cetaceans also emit sounds; and certain shrimp found over rocky bottom in subtropical waters produce sharp crackling sounds by snapping the joint of a lobsterlike claw. As individuals none of these amounts to much as a noise producer, but collectively, when croakers gather on their spawning grounds in breeding season, porpoises collect in schools of hundreds of individuals or the shrimp live as they normally do, in swarms of millions, the production of noise can be tremendous and it can effectively interfere with the use of sonar and similar underwater acoustic gear. In the case of porpoises, W. N. Kellogg in 1958 demonstrated that the production of sound is for echo-ranging purposes, since porpoises easily find fish and avoid obstructions that they cannot see.

Hydrostatic pressure in the sea is of little concern to most forms of life, just as the ordinary atmospheric pressure is of slight influence on terrestrial forms. At sea level, for example, an average man, with a skin area of about 19 sq.ft., is supporting a total atmospheric load of about 40,000 lb.; yet, since this pressure is exerted equally in all directions, it is self-equalizing and insensible. Likewise the tremendous pressures at great depths in the sea are self-equalizing.

Pressure changes are significant to two groups of organisms. One is the fishes equipped with swim bladders. They are unable to make rapid adjustments to changes of depth, and it is not uncommon for fish caught even in moderate depths of water (as cod on continental shelves) to reach the surface with swim bladders abnormally distended. The other group is the air-breathing animals, which for the most part are unable to operate very far below the sea surface. In free dives, men have penetrated to a depth of about 200 ft. without special equipment, 300 ft. with compressed air and 350 ft. with special atmospheres. Helmeted divers have reached 600 ft., breathing a mixture of oxygen and helium. These achievements are far overshadowed by those of the sperm whale. Bruce Heezen in 1957 reported 13 cases of whales tangled in submarine cables, which showed that sperm whales regularly swim along the ocean bottom at depths as great as 3,700 ft. The physiological mechanism that permits them to accomplish this was not explained.

One great difference in physical characteristics between the land and the aqueous environment is in the availability of solid surfaces. These are so common on land as to be taken for granted, but this is not the case in the ocean. It has been shown that in order to carry out their metabolic functions efficiently, bacteria must have a nearby solid surface. Thus the limiting factor in the growth of marine bacteria is usually the lack of surfaces, not of nutrients. A fresh surface introduced into the sea is quickly covered with a slimy film of multiplying bacteria. Organisms such as diatoms, gorgonian corals and probably others secrete antibiotics to inhibit growth of bacteria, but inorganic particles are soon coated with them. Marine sediments are rich in bacteria, which were carried to the bottom on settling particles and were able to multiply vigorously with a plentiful supply of food and of solid surfaces.

2. Phosphorescence.—The production of light by organisms is primarily a phenomenon of the sea (*see* BIOLUMINESCENCE). Phosphorescence, as it is generally called by the mariner, is found in many of the animals of the deep ocean, where it may serve as lure for prey, as protection to frighten away attackers or as an aid in mating, but its most spectacular manifestations are among the plankton of the surface layers, especially in warmer waters. Here a disturbance such as breaking waves or the wake of a ship may stimulate millions of tiny organisms into glowing. Individually each is but a speck, but collectively the light can be bright enough for reading the proverbial newspaper. A special form of this surface luminous activity has been observed in the Arabian sea, where it has long been known to seamen as the "wim-wams." It consists of revolving bands of light, several miles long, rotating slowly about a centre like spokes of a wheel. In 1955 a reliable report was made of several cases where luminous patches in the sea responded to stimulation by the ship's radar, but no explanation of the connection was available.

3. Mass Mortalities in the Sea.—The preceding discussion of life in the ocean has emphasized the factors that encourage organisms to grow and multiply. There also exist, however, physical and chemical relationships in the sea that result in catastrophic destruction of living forms. These relationships can have causes as simple as lowered temperature from an unusually cold winter or lowered salinity from exceptional river discharge. Changes in current can also be responsible, such as the famous El Niño of Peru, which brings unusually warm water south along the coast, with destructive effects first on the fish and then on the guano birds that feed on them. Vertical mixing can carry to the surface water low in oxygen (as in Walvis bay, South West Africa) or high in hydrogen sulfide (as in the Black sea), with fatal results to the surface fauna.

Another more complicated cause is uncommonly heavy growth of dinoflagellates in the surface layers. In many parts of the world these organisms from time to time multiply in such numbers as to colour the ocean surface red. They also produce toxic substances, which if concentrated by mussels or other shellfish render them highly poisonous, and which may also kill fish and invertebrates. The "red tide" of the west coast of Florida is the result of concentrated growth of the dinoflagellate *Gymnodinium brevis*. Both chemical and physical factors are involved in its extraordinary growth. Growth-stimulating factors derived from the coastal bayous are carried out to sea at times of increased river discharge; but only when currents and water temperatures happen to be suitable so that the growth-promoting substances are not widely dispersed can an outburst of the "red tide" develop.

VIII. ORGANIZATIONS FOR STUDY OF THE OCEAN

1. International.—The intercommunicating nature of the ocean has fostered the creation of a number of international organizations devoted to furthering its study. Among these are the International Council for the Exploration of the Sea, with headquarters at Copenhagen, which was established in 1902; the International Commission for the Scientific Exploration of the Mediterranean Sea, established in 1908; and the International Commission for the Northwest Atlantic Fisheries, established in 1949. These three groups are primarily concerned with collecting the oceanographic information required for proper management of the international fisheries in their respective areas. The International Hydrographic bureau, founded at Monaco in 1921, serves as a clearinghouse for information related to hydrography and charting. An Intergovernmental Oceanographic commission, with headquarters in the UNESCO Office of Oceanography, was established in 1961.

2. Europe.—Among the important institutions conducting research on the ocean are the Institute of Oceanology of the Academy of Sciences and the State Oceanographic institute, Moscow; the Havsforskningsinstitut in Helsinki, Fin.; the Oceanographic institute of Göteborg, Swed.; the Geophysical institute of the University of Bergen and the ministry of fisheries laboratory, both at Bergen, Nor.; the German Hydrographic institute, Hamburg, and the Institute für Meereskunde of the Universities of Kiel and Hamburg; the Rijkswaterstaat at The Hague and the Royal Netherlands Meteorological institute at de Bilt; the Institut Océanographique at Paris; and the Thalassolographic institute of Trieste, Italy. In Great Britain, the National Institute of Oceanography at Wormley, Surrey, was established by royal charter in 1949 to centralize work previously conducted in several government departments. Oceanographic work in connection with fisheries is conducted by the ministry of agriculture and fisheries laboratory at Lowestoft and by the fishery board for Scotland laboratory at Aberdeen. Private biological associations maintain laboratories

at Plymouth and at Millport, and training in physical oceanography is offered by Liverpool university. Tide studies are centred at the Liverpool Tidal institute, Birkenhead.

3. **North America.**—In Canada, oceanography is co-ordinated by the Joint Committee on Oceanography, established in 1947. The Fisheries Research board maintains a laboratory at Nanaimo, B.C., and jointly with the Department of Mines and Technical Surveys operates the Bedford Institute of Oceanography near Halifax. The institutes of oceanography at the University of British Columbia, Vancouver, and at Dalhousie university, Halifax, provide graduate instruction in oceanography. The Defence Research board maintains the Naval Research establishment at Dartmouth, N.S., and the Pacific Naval laboratory at Esquimalt, B.C., which work on specialized problems such as sound transmission in the sea.

In the United States, the Chesapeake Bay institute of the Johns Hopkins university, Baltimore, Md., the Institute of Marine Science of the University of Miami, Fla., the departments of oceanography of Texas Agricultural and Mechanical university, the University of Rhode Island, Oregon State university, New York university and the Universities of Hawaii and Alaska, the Scripps Institution of Oceanography of the University of California, La Jolla, the Allan Hancock foundation of the University of Southern California, Los Angeles, and the oceanographic laboratories of the University of Washington, Seattle, are among the colleges and universities that offer graduate instruction and conduct research in oceanography. Woods Hole Oceanographic institution, at Woods Hole, Mass., is a private institution established in 1930 to prosecute the study of oceanography in all its branches.

Among United States governmental organizations, the coast and geodetic survey of the department of commerce, the fish and wildlife service of the interior department, the Coastal Engineering Research centre of the U.S. army corps of engineers, and the U.S. coast guard all have programs of investigation in oceanography. In the naval establishment, the Navy Electronics laboratory at San Diego, Calif., the Mine Defense laboratory at Panama City, Fla., the Naval Ordnance laboratory at Whiteoak, Md., the Naval Research laboratory at Anacostia, D.C., and the naval oceanographic office at Suitland, Md., conduct studies of the ocean. The National Oceanographic Data centre, administered by the navy but financed jointly by several agencies, was established in Washington in 1960.

4. **Other Countries.**—In keeping with its extensive fisheries, Japan has numerous laboratories engaged in oceanographic investigations. The Ocean Research Institute of the University of Tokyo was established in 1962 as a centre for basic research. In Australia, the division of fisheries and oceanography of the Commonwealth Scientific and Industrial Research organization maintains a laboratory at Cronulla, New South Wales. The department of scientific and industrial research operates an oceanographic observatory at Wellington, N.Z. In India, Andhra university at Waltair is active in oceanography. The division of fisheries of the department of commerce and industries maintains a laboratory at Cape Town, S.Af.

OCEANIA commonly refers to land areas scattered throughout the south-central Pacific ocean. The word has, however, been used with many meanings; the most inclusive, though least useful, embraces all insular regions between Asia and the Americas. A more practical definition excludes such nontropical areas as the Ryukyu and Aleutian islands and the Japan archipelago. The most popular usage delimits Oceania further by eliminating Indonesia, the Philippines and Formosa, since those islands and their peoples seem more closely related to the Asian mainland. This leaves an island area bordered by and including New Guinea, Palau and the Mariana Islands on the west, Hawaii and Easter Island on the north and east respectively, and extending southward to Australia and New Zealand. Europeans, when they charted these islands, divided Oceania into four parts: (1) Australia; (2) Melanesia (New Guinea eastward to Fiji); (3) Micronesia (Mariana, Caroline, Marshall and Gilbert islands); and (4) Polynesia (a triangle of many islands, including Hawaii, New Zealand and Easter Island). Ethnological studies cut across the traditional divisions of Oceania. This article reviews events in the settlement of the area, changes involved in the process and gives a survey of the archaeology of Oceania. For later history, administration, trade and further geographical description *see* Pacific Islands; Melanesia; Micronesia; Polynesia; also such articles as Australia, Commonwealth of; Hawaii; Fiji.

ETHNOLOGY

Oceania includes more than 10,000 islands and nearly 500,000 sq.mi. of land. Thirty thousand years ago no human beings lived there. When men entered the area they brought with them plants and animals new to Oceania together with social, political, economic and religious customs from their Asian homeland. Each island became a laboratory in which small communities of people experimented with local resources. Innovation also resulted from contact among island populations, each of which gradually evolved a unique pattern of life. By mid-20th century approximately 2,500,000 islanders were living in Oceania; their earlier cultures were being revolutionized by increased contact with the rest of the world.

Migrations.—Scientists still debate the details of Oceanic migrations, but there is overwhelming agreement on the east-Asian origin of Oceanic peoples. It is well established that during the Pleistocene epoch (Ice Age), which ended possibly 11,000 years

PATTERN OF PACIFIC MIGRATIONS BASED UPON THE THEORY OF THE EAST-ASIAN ORIGIN OF OCEANIC PEOPLES

The original occupation of Australia and New Guinea from the mainland is believed to have begun during the last period of the Pleistocene, about 20,000 years ago

ago, early forms of men were living in Asia and the westernmost islands of the Indies. These islands were then part of a single land mass (Sunda-land) joined to the mainland of Asia. Later, as glacial expanses in the northern hemisphere melted, the waters of the Pacific rose as much as 300 ft. and drowned the land bridges. New Guinea and Australia were also united (as parts of Sahul-land, separated from Sunda-land by a geologically unstable zone of islands including, *e.g.*, the Moluccas, Lesser Sundas and Celebes). Named Wallacea, the intervening region was characterized by ocean depths up to 16,000 ft., with islands never more than 60 mi. apart.

Throughout the last major Pleistocene period small bands of people, employing rafts or crude canoes, crossed Wallacea and made their way by slow stages to New Guinea and Australia. These first arrivals in southwest Oceania have been regarded as representing three principal racial stocks. The Oceanic Negrito stock, dominant among inhabitants of the tropical jungle of Queensland and in the interior of New Guinea, is revealed by short stature, dark skin and frizzly hair. The Murrayian or Ainoid element, present also in the aboriginal Ainu of Japan, characterized by lighter skin, wavy hair and short, quite hairy bodies, survives in mixed form in southeast Australia and in the high plateaus of New Guinea. The Carpentarian stock (sometimes called Veddoid because of similarities with the linear build, dark skin and wavy hair of men of south India) is detected in the appearance of central and north Australians and among the tribes of north and south coastal New Guinea.

The earliest immigrants from the Indies lived by hunting, fishing and collecting wild plant food. They lacked many of the cultural accomplishments of later arrivals from the Asian mainland. Wherever they settled, each group adapted to local conditions and many unique cultures and languages evolved. This heterogeneity became much more pronounced later, and the physical appearance of each population came to reflect differences resulting from mutation, natural selection, admixture, selective mating and small population

These conditions continued in the southwest Pacific for perhaps the first three-quarters of man's residence in Oceania. All of Australia and most of Melanesia were eventually discovered and settled by small colonies of these primitive food-collectors. Before the end of that period, however, a major cultural revolution had begun in Asia, best described as a shift to economies based on plant cultivation and livestock domestication. Such changes favoured a more stable existence, the development of more specialized skills and the concentration of larger populations in more permanent settlements. By 3000–2000 B.C. the first effects of these changes reached Oceania, apparently introduced from east Asia via the Indies and the Philippines by immigrants who are often referred to as Indonesians (or proto-Malays). These brown-skinned peoples, with straight to wavy black hair, medium stature and prominent cheekbones, are believed to have combined an Ainoid ancestry with genetic elements from Mongoloid peoples who were then moving south on the Asian mainland.

The more or less continual movement of Indonesians into New Guinea and other Melanesian islands to the east (although not into Australia in any force) contributed further to the genetic mixture of island populations. The newcomers spoke languages of the Austronesian (or Malayo-Polynesian) family, in time adopted by most of the coastal New Guineans and other Melanesian residents. (Other languages that have survived and are not known to be related to Austronesian, most of them in the New Guinea interior, are simply lumped together and called Papuan.

In like manner most of the food-collecting islanders learned to cultivate taro, yams, bananas and breadfruit introduced by the Indonesians from Asia. In spite of Indonesian influence, the inhabitants of Melanesia continued to display their Negritoid ancestry, and to retain many social and religious customs that resemble those of some Australian aborigines.

The far-flung islands of Micronesia and Polynesia to the north and farther east presented formidable obstacles to would-be migrants from either Melanesia or the Indonesian region. These small islands, in contrast with those settled in the southwest Pacific, did not provide adequate food for long-term support of people skilled only in hunting and other food-collecting techniques. Especially was this true in coral atolls of the Carolines, Marshalls and Gilberts. Furthermore the great distances separating the islands of Micronesia-Polynesia demanded seaworthy craft. These barriers were surmounted probably not later than [illegible] B.C. when Micronesia was entered by voyagers of predominantly Indonesian type not unlike those who had infiltrated Melanesia.

BURT GLINN—MAGNUM

CHIMBU WARRIOR OF NEW GUINEA

Short and dark-skinned, the Chimbu are linguistically and culturally Papuan (non-Melanesian) and probably represent a mixture of Negritoid and the other original genetic stocks from Asia

Limited evidence of prevailing winds, ocean currents and flyways of migratory shore birds suggests that pioneer voyages into Micronesia may have started from the Moluccas in the Indies or from the Bismarcks northeast of New Guinea. Archaeological evidence alternatively suggests a connection with the Philippines. Food producers with improved stone tools in those island regions could have built seaworthy canoes with sails and stabilizing outriggers. In the west Carolines, Palau is only 450 mi. from the Moluccas with four coral isles as convenient stopovers, and is no farther from the Philippines. Truk in the central Carolines is farther from the Moluccas and closer to the Bismarcks but is separated from the latter by nearly 500 mi. of water and only two intervening atolls. Drift voyages by fishermen or local travelers carried off course in storm or calm were probably more significant in the discovery of Micronesian islands than adventurous or colonial expeditions.

By whatever routes they came the discoverers of Micronesia made the small islands livable by supplementing the rich marine resources with such efforts as the cultivation of root and tree crops and the breeding of pigs and chickens. The contrasting environment of high volcanic islands (the Marianas and Palau, Yap, Truk, Ponape and Kusaie in the Carolines) and low coral atolls influenced these adaptations. Unique local development was fostered by geographic isolation, but to the extent that interisland trade existed in some areas (notably the Carolines) local differences perhaps were minimized. In support of these trading expeditions skills improved in canoe construction and handling, and navigation by the stars. Growing communities, associated with larger and more dependable food reserves, sought additional land for expansion. As the flow of immigrants continued—many of them probably forced out by population pressure from east Asia—many Micronesians were vanquished, absorbed or pushed out. Perhaps some even returned to the Melanesian islands of their ancestors or sought refuge in marginal places in that sector of the Pacific, and thereby added confusion to the history of Oceanic settlement by an intrusion of Melanesian-derived but Micronesian-adapted traits.

Micronesians must have taken 60 or 70 generations before some ventured in their sailing canoes to settle larger and more provident islands beyond the bounds of Micronesia. To the northeast lay only empty horizons and to the east only small improvident atolls in the Marshall, Gilbert and Ellice archipelagoes. To the southeast were lush volcanic islands at the eastern extremity of Melanesia which already may have been settled by migratory groups from western Melanesia. Sir Peter Buck proposed that Oceanic "vikings" had sailed from the Carolines through the screen of atolls to the high islands of Samoa, bypassing all of Melanesia. An alternative view suggests that persons from the New Hebrides or adjacent islands in east Melanesia were impelled to sail on to Fiji, Tonga and Samoa, even northward into eastern Micronesia.

While opinions differ as to the precise sequence in the discovery and settlement of Polynesia, few authorities still regard it as a direct migration from the Indies (or even as far west as Asia) by people who spent only a minimum time in Melanesia or Micronesia before reaching Polynesia. Rather the immediate source of Polynesians is placed in central Micronesia or east Melanesia (or a combination of both), and the migration is conceived as a more or less continuous flow of small groups that lasted for centuries and involved many persons. Most of the many islands of Polynesia were probably settled in the period beginning about 1000 B.C. and continuing until A.D. 500, a span of at least 60 generations. In west Polynesia, early centres of dispersal were Tonga and Samoa. In the eastern Pacific the more widely scattered islands, including Hawaii, Easter Island and New Zealand on the outer rim, were settled later from Tahiti and other islands in east Polynesia.

Polynesians in pre-European times were fairly homogeneous in race, language and culture, especially when compared with the Micronesians and the extremely heterogeneous Melanesians. Local variants that existed within Polynesia are explained by a combination of factors. Polynesians, like other Oceanic peoples, have always lived in small communities of only a few hundred persons or even less. Local distinctions in cultural tradition and physical type in such small groups could easily have resulted from the 25 centuries of inbreeding and relative geographic isolation following the first Polynesian settlement. Also, if all Polynesians were not descended from a single group that entered the area in 1000 B.C., but stemmed from a more enduring migration over many generations, then it is reasonable that changes in race, language and culture had meanwhile occurred in the region in which the migration had been initiated. All subsequent migrants into Polynesia from that outside source would reflect these changes.

E. AUBERT DE LA RÜE

IRRIGATED TARO GARDEN ON HUAHINE, SOCIETY ISLANDS

A basic foodstuff of the region, taro came from Melanesia to Micronesia and Polynesia with early settlers. Livestock and such crops as taro helped make many of the small, distant islands habitable

Whatever mixture of racial types exists in the Polynesian people is believed to have occurred mainly prior to dispersal within the Polynesian area. Generally speaking, Polynesians are taller and more robust than Micronesians but this may simply be the product of better living conditions in Polynesia. Although Micronesians display more physical diversity than Polynesians, they are predominantly of the brown-skinned Indonesian type. The Carolinians (apart from Palauans who, like the Marshallese at the other end of Micronesia, exhibit some Negritoid features) closely resemble the Polynesians, with the Gilbertese of east Micronesia intermediate both geographically and genetically. Most Polynesians are regarded as primarily of Indonesian type with a Negritoid strain suggested. This is consistent with the idea of a people that originated in central Micronesia and was exposed to Negritoid elements in east Melanesia before entering Polynesia.

Linguistically, Polynesians reveal a close affiliation with Fijians (most other Melanesian languages are quite divergent, an indication of greater antiquity), and are not greatly different from most Micronesians. Only Palauan and Chamorro (spoken in the Marianas) are excepted since these are more nearly akin to languages of the Philippines and the Indies. About the time that Polynesia was

being settled, Mongoloid Malayans from east Asia (also called deutero-Malay to distinguish them from the earlier, less Mongoloid proto-Malay) overran the Indies and the Philippines, forcing many earlier residents into less desirable inland regions. This tide of Asian humanity touched Micronesia only in its western extension and Melanesia only in places along the north coast of New Guinea. The Polynesians meanwhile, continuing their wanderings well into the Christian era, reversed the direction of their earlier expeditions and left their imprint on such western Pacific communities as Kapingamarangi and Nukuoro in Micronesia, and in Fiji, New Hebrides, Loyalty Islands and various Polynesian outliers along the fringe of Melanesia as far west as the Bismarcks. (*See* also AUSTROASIATIC LANGUAGES; MALAYO-POLYNESIAN LANGUAGES.)

Cultural Change.—When men from England, France, Germany, Holland and Spain explored the Pacific from the 16th to the 18th centuries, their journals reported a seemingly unlimited variety of ways in which Oceanic peoples had met and solved problems of living in a tropical ocean-bound environment. In the New Guinea interior Europeans observed Negrito hunters living in small bands with a minimum of technological and political attainments. They described similarly impoverished aborigines in the Australian wasteland who nonetheless performed elaborate ceremonials and had a seemingly complex kinship organization that defied the visitors' understanding. In some parts of Melanesia they met dark-skinned islanders in small autonomous communities who practised agriculture and accumulated wealth in pigs and shell money but conducted tribal initiations resembling those of Australian hunters. In other Melanesian islands they found other dark-skinned people who showed little interest in the spiritual, but who revealed a consuming passion for genealogies, aristocratic hierarchies and organized warfare, as did many Polynesians and some Micronesians. But in Micronesia Europeans also discovered brown-skinned natives who in many social institutions more closely resembled the mystically inclined gardeners of Melanesia.

Oceania has been described as a vast laboratory in which human experiments in living were tried by about 1,000 groups with as many unique results. The relationship between experimental group and environment was reciprocal. Pottery could not be made in islands without clay deposits, outrigger canoes could serve no purpose in the highland interior of New Guinea, breadfruit trees could not be grown on coral atolls in dry zones. But the islanders did exercise controls over the environment. They bred chickens and pigs on islands that before had supported none; they invented sleeping bags as protection against disease-bearing insects; they transported soil to coral isles where taro plants could not otherwise have been cultivated. The immigrant Indonesians with their superior technology survived in Micronesia where the hunting peoples of Australia would probably have failed.

In social organization, political authority and religious belief the relationship of Oceanic customs to the physical setting was less significant. Thus it was possible for technologically simple tribes in Australia and New Guinea to be as different from each other as they were in kinship and ceremonial practices. Similarly, though Polynesians shared an economy based on fish, coconuts and taro, some groups combined the functions of chief and priest in one man (usually the informal head of an extended family), while Hawaiians developed a semifeudal system of land tenure and political control reinforced by a corps of religious specialists.

Attempts to reduce the cultural systems of Oceania to an orderly scheme have depended much on the divisional concepts of Micronesia, Polynesia, Melanesia and Australia. However, scientific understanding of Oceanic prehistory has been hindered by the perpetuation of these divisions. Melanesia and Australia may be differentiated by certain features of the landscape, but while economic activities of the respective inhabitants were often notably different, social and religious practices suggested a commoner background. The divisional notions of Polynesia and Micronesia fail to distinguish between high and low island habitats that occur in both areas and, as with Australia-Melanesia, the separation of Polynesia from Micronesia is clouded by the occurrence of certain sociocultural institutions in both regions. The distribution of specific traits frequently overrides traditional borders, for example, loom weaving in the Carolines, a few Melanesian islands and none of Polynesia; a simplistic form of wood carving art in Micronesia, Fiji, Tonga and Samoa; hereditary ruling aristocracies in Hawaii, Tahiti and Tonga, some of Micronesia and only Fiji in Melanesia. The traditional divisions of Oceania are useful for geographic description but they fail to coincide with cultural patterns.

Reconstruction of Oceanic history requires information about the physical setting, the techniques, institutions and values brought by island migrants to new settlements and the nature of contacts with other groups, whether based on trade, warfare or ceremonial exchange. But even this knowledge is not enough, since vital clues to any community's history lie concealed in the individual's contribution to group life. Unfortunately Oceanic peoples were not historians in the European sense; they kept no written records but transmitted their knowledge orally. The individual in those traditions remained largely anonymous or assumed some legendary character that may or may not have been related to historic fact.

In the few centuries since Europeans discovered Oceania a revolution has occurred comparable to the changes initiated more than 4,000 years earlier by food-producing Indonesians. The impact of enormously increased contact in World War II was still having its effects in the 1960s. A new culture in the Pacific was emerging, but the same processes of change could be counted upon to produce island communities adapted to the changing scene. (L. E. MN.)

CHILDREN OF MOOREA, SOCIETY ISLANDS, FRENCH POLYNESIA

Like its neighbour Tahiti, Moorea is largely a high island of basaltic lavas. The low island in the background, however, is coral reef

WERNER STOY FROM FPG

ARCHAEOLOGY

The first cultural base that can be traced from Oceanic data is that called Mesolithic (Middle Stone Age). Finds in Melanesia, primarily in New Guinea, suggest that there may have been a still earlier, probably Late Paleolithic, penetration of those lands. That this reached Australia is very dubious and that it moved out into the islands of Polynesia is highly improbable. The Mesolithic people, with a simple hunting, fishing and shellfish gathering culture, spread widely from Asia and southeast Asia through Indonesia and Melanesia into Australia-Tasmania. The Mesolithic way of life must have ended as an important cultural component by 3000–2500 B.C. in Indonesia; remnants of it still endure among a few Australian aborigines on reservations.

Neolithic (New Stone) changes were represented by the addition to the old Mesolithic base of pottery, agriculture, domesticated animals, techniques of abrading, grinding and polishing stone, water craft (canoes) adequate for travel on the high seas and the use of massive stone in building and sculpture. The Neolithic also

until recently, the cultural base of the peoples of Melanesia and Micronesia-Polynesia. Australia-Tasmania, to judge from the Mesolithic cultural level, was settled relatively early, probably during the last glaciation. Tasmanian archaeology is not well understood, but the links that exist point toward Australian relationships. Genetically the Tasmanians show Negritoid relationships, indicating that they must have moved out of Melanesia—for it is there that the nearest true Negritoids live—as very early migrants.

In Australia there were no early or mid-Pleistocene cultures. The Cohuna and Talgai skulls do not vary greatly from Australian norms. Australian prehistory falls into inland and coastal aspects. Since the inland depends upon surface collections, their chronologic relationships are not well understood. A few coastal middens have long period sequences and offer the best hopes of arriving at time sequences for both the coast and, comparatively, the interior. The types of stone tools indicate a relationship with widespread Indonesian and Melanesian Mesolithic cultures.

Specifically, the Hoabinhian I of Indonesia and its pebble choppers, cores and hammerstones are similar to those tools of southeast Australia. Most intriguing of the old Australian stone industries is the Microlithic (small stone). Tiny chipped blades are abundant on inland sites in the southern parts of the continent. These small tools are a world-wide aspect of the Mesolithic. Thus the problems of Australian prehistory are not isolated but are an integral part of those of southern Oceania-Indonesia and southeastern Asia. The chronology of Australian-Tasmanian cultural sequences depends primarily on radiocarbon dating, climatological and geological complexes. South-central Australia undoubtedly supported a culture using microliths and small projectile points as early as 4000 B.C., while a sequence in the Sydney area shows well-developed local cultures about 2,000–3,000 years earlier. These dates are probably minimal (*see* GEOCHRONOLOGY).

Melanesia, the land of Oceanic Negroids, was settled before Australia-Tasmania, first by a Negritoid and then by an Australoid population, both apparently with Mesolithic cultures, and later by Neolithic Negroids. The three subracial groups have mixed extensively and this has beclouded knowledge of their genetic past. Early archaeological remains, presumably often located along the strands, have been covered by waters rising from the glacial ebb about 200 ft. or more below the present stand. Archaeological work in Melanesia as a whole is scant and early sites are rare. An aspect of Oceanic Neolithic culture of southeastern Asian origin is megalithic construction. These large stone remains include platforms, walled areas, heroic human and animal figures, large mortars and pestles, etc. A concentration of Melanesian megaliths exists in eastern New Guinea, the highlands and adjacent islands. Mesolithic sites with older Australian and Indonesian affiliations have been studied. Investigations in the tumuli of the interior of the Ile des Pins, New Caledonia, show large coral-ironstone "concrete" cylinders 6–10 ft. in diameter in their centres, covered with earth. Their builders and functions remain a mystery.

Three levels of cultural change appear in Fiji Neolithic sites: an early level with pig and chicken bones and potsherds showing relief decoration; a middle level in which dog bones were first found and plain pottery prevailed; and the late level characterized by shell concentrations, previously lacking, and incised pottery. Radiocarbon dates place the early period around the time of Christ, the mid-period through the 7th to 10th centuries A.D. and the late period to the 14th century. Pottery relates to the west, into Indonesia. New Caledonian radiocarbon dates run from about 3,000 years ago to within the last few centuries. Therefore Neolithic agricultural pottery makers had penetrated into eastern Melanesia about 1000 B.C.

Major migratory movements of the ancestral Polynesians were almost certainly out of Indonesia. Once thought to have been first into western Micronesia and thence on to the east, they now appear to have skirted along northern Melanesia and finally centred strongly into western Polynesia (Samoa-Tonga) and thence moved on to the Tahiti (Society Islands) and Cook islands whence populations fanned out over the entire Polynesian triangle. Linguistic and archaeological evidences combine to suggest that Samoa was reached by at least 1000 B.C. and Tahiti only a few centuries later. In the 1960s radiocarbon dates secured were A.D. 79 for Samoa, 130 B.C. for the Marquesas Islands, A.D. 386 for Easter Island, A.D. 124 for Hawaii and A.D. 1015 for New Zealand. It appears that the vast area of Polynesia was explored and settled by Neolithic sailors in about a millennium and a half, with New Zealand the latest to be discovered and exploited. It is not possible to consider the later chronology in Polynesia without using the information derived from the carefully kept genealogies which record migrations out from the Society Islands in the 9th, 11th and 14th centuries. These memorized genealogies do not help with the more ancient periods, however, for two reasons: they do not and cannot be expected to carry back that far, and there is a strong possibility that social development had not then evolved a place or need for such records. Sites on the Hawaiian islands of Nihoa and Necker have an archaic type of Polynesian culture, apparently less strongly agricultural and with a less rigidly set social structure. These sites were probably inhabited in the 10th and 11th centuries; local cultural change and probably migrants from the Society Islands in the 12th to 14th centuries brought about the highly developed way of life encountered by the first Europeans.

In the older periods in central Polynesia the assembly courts and long narrow terraced platforms (*ahu*) were separate. In later periods these were combined into the *marae*, a large paved area with a high, often almost pyramidlike terraced platform at one end. Upright monoliths, or slabs in series, were employed as constructional or architectural items. This fusion of different features into the *marae* must have occurred in the Society Islands after the migrations to Easter Island, or the architectural lines of development in the two groups were otherwise separated, because the terraced *ahu* alone is used on Easter Island. The giant stone heads of Easter Island find their closest stylistic relatives in eastern Polynesia from New Zealand to the Marquesas. The technical and mechanical details of carving and handling the statues were within the capabilities of the high Neolithic Polynesians. The Easter Island "script," which is not true writing, is apparently an almost calligraphic sequence of decorative motifs and perhaps of mnemonic aids. Easter Island lacked large forest trees for canoes, hence few woodworking tools are found there. (*See* also EASTER ISLAND.)

Polynesian culture could mold itself to differing environments and mold these to its uses with equal ease. The migrants to New Zealand (Maori) moved from the small tropical Society Islands to a large temperate country. The great forests contained logs for canoes and buildings; fine stones (basalts and jades) existed for tools and ornaments. The New Zealanders developed a stone tool inventory beyond that of the usual Polynesian. Again, the full-fledged *marae*, with *ahu*, does not appear in New Zealand. A large Maori population resulted in the development of extensive middens. Excavations of the earlier sites have indicated that the first colonizers hunted the later extinct giant forms of the flightless bird which they called the moa. These archaic moa hunters must have known agriculture when they arrived in New Zealand, but no evidence of it is found in their middens. Perhaps they became less dependent upon cultivation as they learned to hunt the large and easily conquered game. They lasted, culturally, beyond the period when they could depend on the moa for food—into the 13th century. Whether or not they developed culturally into the classic Maori is not known. The latter may have been new migrants from Tahiti, as some of their artifacts suggest and as the genealogies state. New Zealand, then, was apparently discovered and settled in the 9th, 10th and 14th centuries by several different movements of peoples, called Fleet Maori, from the Society Islands.

Among the items that the Fleet Maori are said to have brought with them was the sweet potato, the *kumara*. This is a South American plant and must have been brought from Peru by an 8,000-mi. round-trip voyage from the Tuamotus or Marquesas, or have made the trip to inner Polynesia from Easter Island after it had been transferred there from South America. At any rate it could not have arrived in Tahiti later than the 13th century and its presence there attests that these islanders were making the longest high seas voyages that man had made up to that time.

The Tonga group of western and central Polynesia was influ-

enced by contact with Fiji; Tongans transferred Melanesian traits from there to other parts of Polynesia and returned the favour with Polynesian traits brought to Fiji. Most interesting archaeologically is the fact that pottery, most like some from New Caledonia, was once made on Tonga and then, not proving to be a necessary adjunct of the culture, became a lost art. Pottery has also been found on Samoa, associated with an occupation dated by radiocarbon in the 1st century A.D. Pottery appears in the Marquesas in the earliest excavation dated there, also by radiocarbon, about a century later. Thus the early, and probably the earliest, settlers in these islands made and used pottery. Probably they were absorbed or extirpated by later arrivals who did not. The *langi* of Tonga, stone-faced burial mounds, cannot be older than the 11th century. The great Tongan trilithon is a three-piece gateway 17 ft. high and 19 ft. wide. The visible portion of the monument must weigh approximately 100 tons. There are traditional data concerning the methods employed and the reasons for its erection. Tongan stonework appears to have had a quick efflorescence in the 13th to 16th centuries. Widespread rough stonework, rarer stonecutting, failure to break joints, occasional use of L-shaped stones as corner ties and cut slabs often weighing many tons are characteristic of Polynesian architectural stonework.

Highly conventionalized stone carvings, developed upon a tradition of wood carving, employed a heavy squat body, flexed legs with short thighs, heavy calves, forearms over the abdomen and exaggerated head and facial characteristics. These variations are discernible from Hawaii to New Zealand in stone, wood and as petroglyphs. This art style appears to have its origins early in Indonesia. Burial practices of Micronesia and Polynesia are varied. Commoners were often buried or exposed on the strand while nobles were buried in vaults, mummified or coffined.

Most of the islands of Micronesia are atolls, as are the equatorial islands of Polynesia. These low islands offered little to the Neolithic migrant in the way of arable land, forests or stone; *Tridacna* shell became a substitute for stone for tools—adzes, pestles, etc. It is only on the largest atolls and on the few volcanic islands in the Carolines and Marianas that archaeological evidence can be expected, not only of recent cultural change but of traces of the earliest migrants.

Megalithic constructions occur throughout Micronesia on the high (volcanic) islands, as they do in Polynesia. Excavations on the Marianas have uncovered extended burials, shallow middens and an enormous number of potsherds of a red utilitarian ware. Later material is dated by radiocarbon at A.D. 845; the earliest date, 1527 B.C., is associated with a hard red pottery. Even older material is found and Neolithic settlers were in Saipan at least as early as 2000 B.C., if the radiocarbon dates may be trusted.

The Palau Islands and Yap also supported peoples who made pottery and who are related linguistically and culturally to the Philippine Islands and Malaysia to the southwest. Stone platforms and the stone cartwheel money of Yap are the megalithic traits of that island. Palau, although partly volcanic, lacked good stone for cutting tools, and most of the adzes, etc., were made of *Tridacna* shell. Archaeological remains include megalithic constructions and carvings, large terraced hills and money of glass armrings sawed into sections, and glass beads presumably traded from the Philippines. Pottery from the later period is a coarse red ware. Deep in the terraced sites this is replaced by a thin dark ware. Both archaeology and tradition vouch for periods of population growth and cultural evolution, with megalithic and earthwork construction, followed by cultural decay and abandonment of the great sites on the volcanic islands, and then a resettlement only a few centuries before European contact. On Yap a radiocarbon date of A.D. 176, the earliest secured, indicates that agricultural people, making a fine red pottery, were living at this period on the Yap archipelago.

OCEANSIDE, a resort city of southern California on the Pacific coast, is 40 mi. N.W. of San Diego at the mouth of the San Luis Rey river. One of the famous California missions San Luis Rey, founded in 1798, is located there and Camp Pendleton, a major U.S. marine corps base, is immediately to the north.

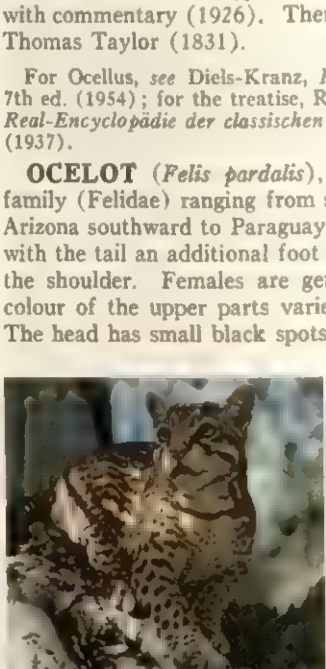
Incorporated in 1888, Oceanside grew slowly before World War II. From 1940 to 1950, however, the population nearly tripled. A mild, dry climate combined with an ocean beach, fishing facilities, municipal swimming pools, a community centre and several golf courses provide recreation for residents and vacationers. The economic life depends largely on the tourist trade, services to Camp Pendleton and light industry. Oceanside established the council-manager form of government in 1947. For comparative population figures *see* table in CALIFORNIA: *Population.* (A. F. Mn.)

OCEANUS, in Greek mythology, the river that encircles the earth (conceived as flat). Beyond it, to the west, are the land of the Cimmerii where the sun never shines, the country of dreams and the entrance of the underworld. In Hesiod's *Theogony* Oceanus is the son of Uranus and Gaea, the husband of Tethys father of 3,000 streams and 4,000 ocean nymphs. In Homer he is the origin of the gods. As a common noun the word gets practically the modern sense of ocean.

OCELLUS LUCANUS (OCELLUS OF LUCANIA; Greek spellings of the name vary between OKELLOS, OKKELOS, EKELLOS etc. (6th?–5th century B.C.), Greek philosopher of the Pythagorean school, was perhaps a pupil of Pythagoras himself. His name was attached to a later treatise *On the Nature of the Universe* (current in the 1st century B.C.), which reflects many of the views ascribed to Philolaus (*q.v.*). The best edition is by R. Harder with commentary (1926). There is also an English translation by Thomas Taylor (1831).

For Ocellus, *see* Diels-Kranz, *Fragmente der Vorsokratiker*, vol. i, 7th ed. (1954); for the treatise, R. Beutler, "Okellos," Pauly-Wissowa *Real-Encyclopädie der classischen Altertumswissenschaft*, Halbband 34 (1937).

OCELOT (*Felis pardalis*), an American species of the cat family (Felidae) ranging from southwestern Arkansas, Texas and Arizona southward to Paraguay. Adults are from 3 to 4 ft. long with the tail an additional foot or more and stand about 1½ ft. at the shoulder. Females are generally smaller than males. The colour of the upper parts varies from pale gray to deep brown. The head has small black spots, and there are two black bars on the cheeks. Four or five parallel black stripes are present on the neck, and black-edged elongate spots of dark colour are arranged in chainlike bands on the body. The underparts are whitish, and the tail is marked above with dark bars or blotches.



© ENCYCLOPÆDIA BRITANNICA

OCELOT (FELIS PARDALIS)

Ocelots are excellent climbers and inhabit forested or brushy regions. They hunt chiefly at night and feed upon small to medium-sized reptiles, birds and mammals. Breeding may occur at any season, and a litter usually contains two young, which resemble the adults in colour pattern but are of a darker shade. Ocelots are easily maintained in captivity and some are readily tamed. The smaller margay (*q.v.*) resembles the ocelot in gen-

eral appearance and in range, but differs in certain features of the pelage and skull. *See* also CAT; CARNIVORE. (J. N. L.)

OCHINO, BERNARDINO (1487–1564), Italian Protestant reformer, important for the influence of his mystical and rational tendencies on the thought of left-wing Protestantism. A native of Siena, he was the vicar-general of the newly founded order of the Capuchins in Italy and was so renowned as a preacher that the pope had to regulate his engagements. Commissioned to read and refute Protestant works, he was himself converted, but did not at first declare himself openly because of the hope that Italy as a whole might embrace the reform. When the Roman Inquisition was established in 1542 he was summoned to Rome but instead fled over the Alps to Geneva. There he demonstrated his Protestantism by marrying a refugee from Lucca. After an interval he was made in 1545 the pastor in Augsburg of a congregation of young German clerks of the banking house of Fugger who had served their apprenticeship in the branch at Venice. When in the Schmalkaldic War the emperor captured Augsburg, Ochino fled to England and there played a prominent part in the Reformation under Edward VI. His *Tragoedie or Dialoge of the Unjuste Usurped Primacie of the Bishop of Rome* (1549) lauded the reforms instituted by Henry VIII and Edward VI. Then came the Catholic Mary I and Ochino fled to the continent. He was made the pastor of a congregation of Italian refugees at Zürich but soon alienated the magistrates and ministers of the city by a series of indiscretions. His tract against the Roman view of purgatory was deemed untimely when Zürich was in imminent danger of attack by the Catholic cantons. His assertion that the differences over the Lord's Supper between the Zwinglians and the Lutherans were only a bagatelle offended both parties. And his description of predestination as an inextricable labyrinth in a tract dedicated to Elizabeth I outraged the Calvinists. To avoid the local censor Ochino brought out at Basel his *Dialogi XXX* (1563), in one of which his defense of monogamy was felt to be inferior to his apology for polygamy. He was banished and, with four children (his wife being dead), he set out in Dec. 1563 for Poland. There his *Tragoedie* was issued in Polish with adaptations to the local situation. However the Catholics persuaded the monarch to banish all foreign dissidents and in 1564 Ochino again took to the road. He died in Moravia toward the end of 1564. There is no evidence in his writings that he was, as claimed by adversaries, an Anti-Trinitarian, but he did interpret the atoning death of Christ as having effected a change only in the attitude of man toward God rather than in that of God toward man. This theology affected the Socinians.

OCHOA, SEVERO (1905–), Spanish-U.S. physician and biochemist, co-winner with Arthur Kornberg of the 1959 Nobel prize for medicine, was born in Luarca, Spain, on Sept. 24, 1905. He received an A.B. degree from Málaga college in 1921 and an M.D. degree from the University of Madrid in 1929. In 1929–31 he was a student and research associate at the Kaiser Wilhelm institute in Berlin, and in 1932–33 he was at the National Institute of Medical Research in London. He returned to Spain in 1934 to teach in the physiology department of the University of Madrid, but left again in 1936 because of the Spanish Civil War. He pursued his researches at Heidelberg in 1936–38 and at Oxford in 1938–40. In 1940 he went to the United States, working first as an instructor and research assistant in pharmacology at Washington university in St. Louis. In 1941 he joined the faculty of the college of medicine of New York university as a research assistant in pharmacology; he was chairman of the school's department of pharmacology from 1946 until 1954, when he became chairman of the department of biochemistry.

Ochoa's major contributions were in the intermediary metabolism of the cell. He was one of the first to provide evidence that the energy from metabolism is stored and utilized by means of the so-called "high energy" phosphate compounds. He and his co-workers did much to clarify the details of the metabolic transformation of such key compounds as acetic and pyruvic acids to carbon dioxide, fat, etc. In 1955 he described the finding of an enzyme system that led to the synthesis of compounds resembling naturally occurring ribonucleic acid (RNA); for this work he was awarded a share of the 1959 Nobel prize. The increasingly positive evidence that RNA is the chief template or specific pattern for protein synthesis by the cell marked this finding as uniquely important. (R. LE.)

OCHOA Y RONNA, EUGENIO DE (1815–1872), Spanish scholar and writer, was born in Lezo (Guipúzcoa). Of minor importance for original works, his militantly literary review *El Artista* (1835–36) contributed significantly to the success of romanticism and he was the first critic to acclaim the realist novel of Fernán Caballero *La gaviota* in 1849. As editor for Ribadeneyra, Madrid, and more particularly of Spanish classics (ballads, novels, prose, plays of L. de Moratín, Lope de Vega, Calderón de la Barca and Tirso de Molina) for Baudry, Paris, he reintroduced Europe to Spanish literature. His *Apuntes para una biblioteca de escritores españoles contemporáneos* (1840) is still useful. He compiled a catalogue of Spanish manuscripts in the libraries of Paris (1844). He died in Madrid. (R. F. B.)

OCHRE, a native earth coloured with hydrated iron oxide. It varies in colour from pale yellow to deep red, brown and violet. There are two kinds—one having a clayey basis, while the other is a chalky earth; the former variety is in general the richer and purer in colour of the two. Both kinds are widely distributed in beds or pockets, mainly in stratified rocks and rubble and rarely as extensive deposits. Some ochres require only grinding, whereas other varieties require calcination whereby the original colour is modified. In the calcination process the associated earth exercises a marked influence, clayey ochres developing red and violet tints, while chalky varieties take brownish-red and dark brown hues. The well-known ochre, terra di Siena, which in its native state is a dull-coloured earth, assumes when burned a fine warm mahogany-brown hue highly valued by artists. Ochres containing much organic matter are sometimes calcined to improve their drying properties in varnish or oil.

Ochres are also artificially prepared in large quantities—Mars yellow is either a pure hydrated ferric oxide or an intimate mixture of that substance with an argillaceous or calcareous base, and by careful calcination they can be transformed into Mars orange, violet or red, all reliable pigments.

OCHS, ADOLPH SIMON (1858–1935), U.S. newspaper publisher who made the *New York Times* one of the world's greatest newspapers, was born in Cincinnati, O., on March 12, 1858, of Jewish parents who had emigrated in their youth from Bavaria. In 1865 the family settled in Knoxville, Tenn. While still a schoolboy Adolph delivered newspapers; at the age of 11 he was an office boy and at the age of 14, a printer's devil on the *Knoxville Chronicle*. In 1875–76 he was a compositor for the *Louisville* (Ky.) *Courier-Journal;* in 1877 he helped establish the *Chattanooga Dispatch;* and in 1878, at the age of 20, he gained control of the decrepit *Chattanooga Times* for $250. He soon placed the *Times* on a firm basis, and made it one of the leading newspapers in the south.

In 1896 Ochs acquired controlling ownership of the financially faltering *New York Times*, and formed the New York Times company. He steadily strengthened the paper's journalistic and financial position, raising its circulation from 9,000 in 1896 to 466,000 daily and 730,000 Sunday copies in 1934. In 1901 Ochs purchased the *Philadelphia Times*, which he merged with the *Public Ledger* and sold to Cyrus Curtis in 1912. He was a founder of the Southern Associated Press, and from 1900 to his death in 1935 was a director of the Associated Press.

The influence of Ochs upon newspaper publishing in the United States was marked and highly beneficial. Entering New York publishing when "yellow journalism" was at its height, in competition with the richest and most powerful newspapers in America, he boldly adopted the slogan, "All the News That's Fit to Print," and devoted his paper, not to sensations, but to giving intelligent readers a daily news report that was trustworthy and complete. In a few years he made the *New York Times* an outstanding example of enterprise in news gathering, and ultimately

the most widely respected and quoted newspaper in the United States. Ochs introduced such innovations as a book-review supplement and rotogravure printing of pictures and pressed for higher standards in the presentation of advertising.

Interested in making accurate source material available to the public, in 1913 he began publishing the *New York Times Index*, the only complete U.S. newspaper index, and, in 1925, advanced $50,000 annually for ten years toward the cost of the editorial preparation of the *Dictionary of American Biography*, repayment to be made from royalties. In 1918 the *Times* was awarded the first Pulitzer gold medal in journalism for meritorious public service. Ochs died on April 8, 1935, in Chattanooga.

Appraisals of Ochs' influence may be found in K. N. Stewart and J. Tebbel, *Makers of Modern Journalism* (1952); E. H. Ford and E. Emery, *Highlights in the History of the American Press* (1954); Gerald Johnson, *Honorable Titan: a Biographical Study of Adolph S. Ochs* (1946).

OCKHAM, WILLIAM (WILLIAM OF OCCAM) (*c.* 1280–1349), English schoolman, known as Venerabilis Inceptor. Born probably at Ockham, Surrey, he joined the Franciscans around 1300. At Oxford he studied the arts prior to 1310, and theology, 1310–15, lectured on the Bible, 1315–17, and the *Sentences*, 1317–19, and prepared himself for his doctorate, 1319–23. Accused of heresy by the chancellor of Oxford in 1323, he was summoned to Avignon to account for some of his doctrines. He was confined to his convent from 1324 to 1328.

Pope John XXII ordered various theses from his works to be examined by the masters of theology in 1325–27, but his works were never actually condemned. In 1328 his championship of the Spirituals, a branch of the Franciscans, brought him into further conflict with the pope, and as a result he and Michael of Cesena, general of the Franciscan order, joined the emperor Louis of Bavaria who was at that time in contest with the papal curia. Expelled from the order in 1331, Ockham came into sharper conflict with the pope, this time on theological grounds. Yet, when Michael of Cesena died in 1342, Ockham received from him the official seal of the order, and was recognized as general by his party. He died at Munich in 1349, having tried to be reconciled to the church after the death of the emperor (1347).

Ockham was one of the most interesting figures in the great contest between pope and emperor, which laid the foundation of modern theories of government. In the *Opus nonaginta dierum* (written in 1330), and its successors, the *Tractatus de dogmatibus Iohannis XXII papae* (1335–38) and in the *Defensorium contra errores Iohannis XXII papae* (1335–39), Ockham only incidentally expounds his views as a publicist, the *Compendium* being of special interest because it selects four papal constitutions that involved a declaration against evangelical poverty, and insists that they are full of heresy. The *Octo quaestiones de potestate papae* (1339–42) attacks the temporal supremacy of the pope, insists on the independence of kingly authority, which he maintains is as much an ordinance of God as is spiritual rule and discusses what is meant by "state." His views on the independence of civil rule were even more decidedly expressed in the *Consultatio de causa matrimoniali*, in which he contends that it belongs to the civil power to decide cases of affinity. By 1343 his great work, the *Dialogus*, was in circulation. His last political work, *De electione Caroli IV*, restates his opinions upon temporal authority.

In philosophy, Ockham's most significant doctrines fall within the field of psychology, metaphysics, logic and theodicy. In the first, he contends that since singulars alone exist, the universal has an objective value only inasmuch as it is thought; that the *intellectus agens* ("active intellect") and its end product and the *species intelligibiles* are superfluous because abstraction follows naturally upon perception or intuition, the fundamental forms of human knowledge; that will and not intellect is the primary faculty of the soul, and that both faculties, like memory, are identical with the substance of the soul; and that a *forma corporeitatis* ("substance of the body") must be admitted if the independence of the soul is to be preserved. In metaphysics, Ockham teaches that matter has its own essence apart from form; that accidents are only aspects of substance; that the problem of individuation is meaningless because each thing is singular in itself; and that between essence and existence there is no real distinction. The famous dictum—*pluralites non est ponenda sine necessitate* ("multiplicity ought not to be posited without necessity")—has become known as "Ockham's razor," though it had already been stressed by other Scholastics. In logic, next to Albert of Saxony, Ockham is the most powerful systematist of the middle ages. In theodicy, he asserts that the existence of God and his attributes, including his unity and infinity, are not provable by a strict syllogism.

In theology, Ockham has been considered as a forerunner of Martin Luther and the originator of theological skepticism. Both affirmations are inexact: Ockham did not make much of the philosophical arguments of earlier theologians, and applied to theology his famous "razor"; however, he was respectful of tradition and traditional understanding of the Bible. *See* also NOMINALISM.

(E. M. Br.)

OCKLEY, SIMON (1678–1720), English orientalist, whose chief work is *The Conquest of Syria, Persia, and Ægypt, by the Saracens*, generally known as *The History of the Saracens*. Born at Exeter in 1678, he was educated at Queen's college, Cambridge, later becoming a fellow of Jesus college and vicar at the nearby village of Swavesey. In 1711 he was appointed professor of Arabic at Cambridge. Being the father of a large family and insufficiently paid he fell into debt in his later days and was for a time imprisoned in Cambridge castle. His troubles are related in Isaac D'Israeli's *Calamities of Authors*. He died at Swavesey on Aug. 9, 1720.

Ockley's first book was the *Introductio ad linguas orientales* (1706) in the preface of which he urged the importance of a knowledge of oriental literature for the study of theology. For his *History of the Saracens* he took as his authority a manuscript of the pseudo-Waqidi's *Futuh al-Sham* ("Conquest of Syria"), which is historical romance rather than history, but his book was widely read and long remained the standard English work on the early history of Islam. He also published a number of translations including *The Sentences of Ali* (1717), a translation of the sayings of the Prophet's son-in-law.

O'CLERY, MICHAEL (1575–1643), Irish chronicler, who directed the compilation of the *Annála Ríoghachta Éireann* (*The Annals of the Four Masters: see* IRISH LITERATURE: *Gaelic Literature: Late Period*), a work of incalculable importance to Irish scholarship, was born at Kilbarron, Donegal, in 1575, the grandson of a chief of his sept. He was baptized Tadhg but took the name Michael when he became a Franciscan. He had already gained a reputation as an antiquary when he entered the Irish college at Louvain; and, in 1620, Hugh Macanward, the warden of the college, sent him back to Ireland to collect manuscripts. Assisted by other Irish scholars he began to collect and to transcribe everything of importance he could find. The results were the *Reim Rioghroidhe* (1630), a list of kings, their successions and their pedigrees, with lives and genealogies of saints, the *Leabhar Gabhala* (1631), an account of the successive settlements of Ireland; and the famous *Annals* (1636), a chronicle of Irish history from antiquity to 1616. At first a mere record of names, dates, battles, etc., with occasional quotations from ancient sources, the *Annals* begin to take on the character of a modern literary history as they approach the author's own time. O'Clery also produced a *Martyrologium* of Irish saints, an Irish

glossary and other works. He worked in very humble circumstances and died at Louvain in 1643. (A. CR.)

O'CONNELL, DANIEL (1775–1847), Irish political leader, known as the Liberator and first of the great 19th-century Irish parliamentary leaders, was born on Aug. 6, 1775, near Cahirciveen in County Kerry. He was adopted as a child by an uncle, known as Hunting Cap, who had organized a flourishing contraband trade with France. Daniel was sent to France to attend the Roman Catholic colleges at St. Omer and Douai and when the Austrian Netherlands were occupied by the French Revolutionary armies, O'Connell escaped to England. These early experiences coloured his later career and though he was inspired by the new doctrines of popular sovereignty he was opposed to revolutionary excess. After studying law in London he was called to the Irish bar in 1798 and achieved prominence by his denunciations of the Act of Union whereby the Irish parliament was extinguished. He believed that any assembly claiming to represent the Irish people must insist on the abolition of the anti-Catholic laws. O'Connell proceeded to revive the agitation for equal rights on broader lines than previous attempts and undertook the cause with boldness and energy. He had outstanding gifts as a lawyer and his work both in Dublin and on circuit brought him a national reputation; and as a demagogue he could excite or pacify the illiterate masses, who regarded him as their champion.

O'Connell circumvented the government's suppression of representative committees by organizing a nationwide series of "aggregate meetings" of Catholics to petition for strictly legal demands. His appeal was sufficiently wide to gain the support of Protestants. His defense of John Magee, a Protestant journalist, who was prosecuted in 1814 for criticizing the viceroy, aroused vast enthusiasm since he used the occasion to denounce the entire system of government in Ireland. Nevertheless Magee was fined heavily and O'Connell's wealthier supporters were deterred for some years. By the time of Lord Wellesley's appointment as viceroy in 1821, O'Connell's fighting spirit had revived. He began to organize a huge popular movement, financed by monthly subscriptions of 1*d.* from all members of the Catholic association. It spread rapidly and its very size precluded suppression; liberal support in England was gained and several bills were introduced for Catholic relief, only to be rejected by the house of lords. A new generation of prosperous and educated Catholics gained confidence from his efforts and example. In 1828 O'Connell contested a by-election at Clare although as a Catholic he would be unable to take his seat. His overwhelming victory convinced the prime minister, the duke of Wellington, of the necessity for concessions to avert civil war and led to the Emancipation act (1829).

O'Connell then took his seat in the house of commons where his ability and personality commanded attention and invited support. He became the leader of the Irish members who came to be known as "O'Connell's tail." He then turned his attention to the repeal of the union of 1800. The Whigs, who had supported O'Connell in 1828–29, when in office after 1830 proved less sympathetic and the rift was only sealed by the bargain, known as the Lichfield House compact (1835) whereby O'Connell promised a period of "perfect calm" while the government passed urgent measures of reform. O'Connell's position in parliament became more decisive after 1834. He helped to defeat Sir Robert Peel's Conservative government in April 1835 and a weakened Whig ministry returned to office. They continued in office until 1841 despite mounting difficulties, largely because of Irish support, given in return for moderate reforming measures in Ireland and because the Conservatives had given no indication that they intended to do anything for Ireland. He had refused the office of Master of the Rolls from Lord Grey and later rejected an offer of the attorney generalship. His friends organized the annual O'Connell tribute to make up for his loss of income from the law and to help the party funds.

By 1840 cooperation with the Whigs had achieved nothing, funds were sinking and O'Connell was urged to revive the agitation for repeal of the union. He founded the new Repeal association and after a difficult start a series of monster meetings was held in all parts of Ireland. They assumed vast proportions without any open collision with the law and during 1843 O'Connell virtually abstained from attending parliament. The climax of this program, a meeting at Clontarf, near Dublin, was intended to assemble 1,000,000 supporters but was prohibited in Oct. 1843 and military precautions were taken. O'Connell and his colleagues were imprisoned and fined but the sentence was quashed on appeal to the house of lords, and the men were released in 1844.

By then his health was failing and an open conflict developed with the younger men who became known as Young Irelanders and who were clamouring for more active leadership. By 1845 O'Connell's strength was almost gone but he made an effort to obtain government relief during the potato famine. Traveling to the south in search of sunshine he died at Genoa while on his way to Rome, on May 15, 1847. His death revived his popularity and he was widely acclaimed as the liberator of a downtrodden people. *See* IRELAND: *History*.

BIBLIOGRAPHY.—There are lives of O'Connell by his son John O'Connell (1846) and by W. Fagan (1847). *See* also the biographies by R. Dunlop (1900) and D. R. Gwynn (1947) and *Correspondence of Daniel O'Connell*, ed. by W. J. Fitzpatrick (1888). (D. G.)

O'CONNOR, FEARGUS EDWARD (*c.* 1796–1855), the most prominent Chartist leader, was born at Connorville in County Cork, Ireland, probably on July 18, 1796, the son of the Irish Nationalist politician Roger O'Connor. He claimed royal descent from the ancient kings of Ireland. He studied law and was admitted to the Irish bar in 1830. He turned from law to politics, however, and entered parliament as member for County Cork in 1832 and was a follower of Daniel O'Connell. He quarreled bitterly with O'Connell on grounds of policy as well as through a clash of temperament and ambition, and was unseated in 1835. Thereafter he turned to radical agitation in England although he continued to press Irish grievances and to seek Irish support. He gathered enthusiastic crowds, particularly in the discontented north of England, and on the publication of the Charter in 1838 became the best-known Chartist leader. Owing to his rough humour, his energy and his invective he became their most popular speaker and his journal, the *Northern Star* (1837), gained a large circulation. He outbid local Chartist leaders in their own strongholds and succeeded in making Chartism (*q.v.*) a mass movement of protest. Both his methods and his views led him into a series of quarrels with other Chartist leaders, particularly William Lovett, and at the convention of 1839 these differences were exposed. Although not concerned in the "insurrection" of 1839 he was imprisoned for a year for seditious libel. After 1841 he acquired a position of almost undisputed leadership in Chartism, but he was unable to lead the movement to victory.

He vacillated in his attitude toward the middle classes and even toward the Charter itself, concentrating in the mid-1840s on his land plan, a scheme for settling urban workers on small holdings. The plan failed, and although O'Connor was elected to parliament for Nottingham in 1847, his power was waning. So too were his abilities; there were many signs that his egocentricity bordered on madness and the failure of the Charter in 1848 marked the beginning of the end. O'Connor was declared insane in 1852 and died in London on Aug. 30, 1855. (A. BRI.)

OCOTEPEQUE, a small department in western Honduras that borders El Salvador and Guatemala.

Population (1961) 52,989. The departmental capital and largest town, Nueva Ocotepeque, had only 4,118 people in 1961. The population, consisting mostly of highland Indians, is exceedingly isolated and has to depend entirely on pack and cart transportation. The department has no all-weather roads and all settlements are in small highland valleys. Although only 15% of the land in farms is cultivated, Ocotepeque ranks first in the nation in the production of wheat, third in tobacco and seventh in potatoes. Several handicraft industries are significant locally. (C. F. J.)

OCOTILLO (*Fouquieria splendens*), a North American shrub of the candlewood family (Fouquieriaceae), called also coachwhip, Jacob's staff and vine cactus. It is a characteristic shrub of rocky deserts from western Texas to southern California and southward in Mexico. Near the base the stem divides into several slender, erect, furrowed, intensely spiny branches, usually from 8 to 20 ft. high. It bears small rounded leaves, the midribs of

which harden into the spines, and showy bright-scarlet flowers in branched terminal clusters, 6 to 10 in. long. The ocotillo is sometimes grown as a hedge plant in its native range.

OCTAVIA, in Roman history, the name of three women of the Julio-Claudian house.

Octavia Maior, half sister of Octavian (later the emperor Augustus), the daughter of Gaius Octavius by his first wife, Ancharia. She married Sextus Appuleius and their son of the same name was consul in 29 B.C.

Octavia Minor (before 63–11 B.C.), full sister of Octavian, the daughter of Gaius Octavius and his second wife, Atia. She was probably born in 69. She married in 54 Gaius Marcellus by whom she had two daughters, Claudia Marcella *maior* and *minor*, and a son, M. Claudius Marcellus (*see* Marcellus). On the death of Gaius Marcellus in 41 she was married to Mark Antony with the aim of reconciling him with her brother. This succeeded at first and later, in the friction of 37, a reconciliation, again the result of her efforts, took place at Tarentum. In 36 however Antony left for the Parthian War and continued his liaison with Cleopatra (*see* Antonius); although Octavia took out troops and money to him (35) he refused to see her and formally divorced her in 32. She lived an exemplary life, bringing up Antony's children by Cleopatra as well as her own.

Octavia (d. 62), daughter of the emperor Claudius and Messallina, was married in 53 to Nero (*q.v.*), who divorced, banished and eventually murdered her. The extant Latin tragedy *Octavia* deals with her misfortunes.

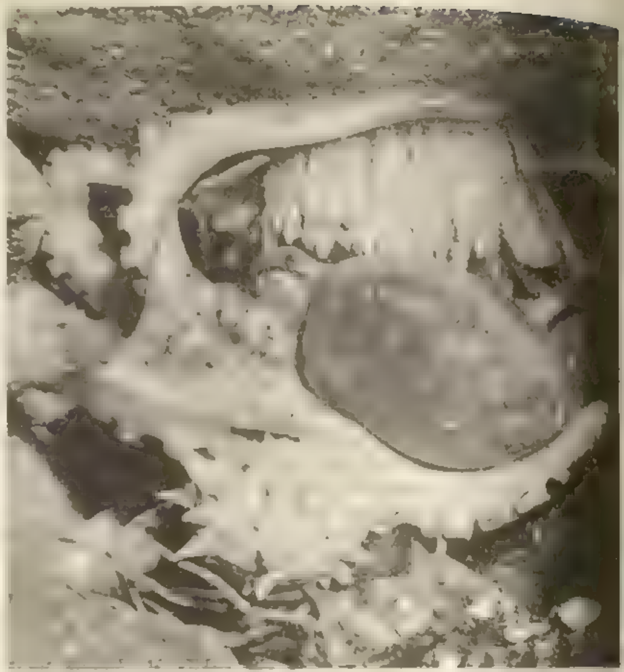
OCTOBER, the tenth month of the modern calendar, with 31 days. Its name (from Lat. *octo*) records the fact that in the early Roman calendar, which began with March, it was the eighth month. Following the precedent of July and August, several attempts were made to rename it in honour of Roman emperors or members of their families, *e.g.*, Domitianus, Herculeus (for Commodus) and Faustinus (for Faustina the Elder), but without lasting success. The witches, hobgoblins and ghosts of Halloween (October 31), still familiar in children's masquerades, are apparently relics of a pre-Christian Celtic feast of the dead, held at this season. (F. R. Wn.)

OCTOPUS, in popular terms any member of the eight-armed cephalopods, order Octopoda; technically, a member of the genus *Octopus*, a large group of widely distributed, shallow-water mollusks. About 36 genera of octopods are known, being divisible by habitat into four broad groups: those living in the littoral or shallow seas (*Octopus, Eledone*), in deep water on the bottom (*Benthoctopus, Bathypolypus*), oceanic in the upper layers (*Tremoctopus, Argonauta, Ocythoe*) and free-swimming in deep water (*Cirroteuthis, Eledonella, Grimpoteuthis*).

Shallow-water octopods vary greatly in size, the smallest, *Octopus arborescens*, about 1½ in. long, occurs in the Indian ocean. The largest may be the giant *Octopus dofleini*, from Alaskan waters, of which one specimen had an arm spread of about 32 ft.; the body proper, however, was only about 18 in. long.

Large octopods have long enjoyed a reputation for ferocity, no doubt because of their sinister appearance, and exaggerated stories of their attacks are numerous. By nature they are retiring animals, but attacks on man are well authenticated though seldom fatal. A few cases are on record of fatalities caused by their bites when handled carelessly, a venom being secreted by the posterior salivary glands in certain species.

The common octopus (*Octopus vulgaris*) is widely distributed in tropical and temperate seas throughout the world. It ranges from Connecticut to Brazil in the western Atlantic and from Britain to Africa in the eastern Atlantic. It lives in holes or crevices along the rocky bottom and is secretive by nature, feeding mainly on crabs and other crustaceans. It has been credited with considerable intelligence, based largely on the extensive studies on learning and memory carried out by J. Z. Young and others at the zoological station at Naples, Italy. *O. vulgaris* has a saccular body; the head is only slightly separated and bears large, complex eyes and eight contractile arms surrounding the mouth. The arms are beset with two rows of fleshy, deeply set suckers capable of great holding power. The mouth is equipped



BY COURTESY OF MARINELAND OF FLORIDA

OCTOPUS (OCTOPUS VULGARIS) IN ITS LAIR WITH HANGING EGG CLUSTERS

with a pair of sharp, horny beaks for biting and a filelike organ, the radula, for drilling shells and rasping away flesh.

In American waters the common octopus mates in the winter, the male passing the spermatophores (sperm bundles) directly into the mantle cavity of the female by means of a specialized hectocotylized arm. The eggs, about ⅛ in. long, are laid in winter and early spring in festoons under rocks and in holes, the total number of eggs amounting to 50,000–180,000. The female guards the eggs during the four to eight weeks required for the larvae to hatch. During this time the female broods over the eggs, cleaning them with her suckers and agitating them with water from her funnel. Upon hatching, the tiny octopods, which closely resemble their parents, are unable to take up a bottom life immediately and spend several weeks in the drifting plankton. In other species, such as *Octopus briareus* of the southeastern United States and Caribbean, the eggs are comparatively large, about ½ in. long, and are laid in a single layer under rocks; the young upon hatching are more developed, lack a planktonic stage and immediately take refuge on the bottom.

Little is known of the life history of the bottom-dwelling deep-water octopods such as *Bathypolypus arcticus*, which is distributed from Florida to Scandinavia and Siberia. Many of the deepwater forms show modifications such as reduction of the gills and loss of the radula.

Oceanic octopods dwelling in the upper layers are largely plankton feeders (*Tremoctopus, Ocythoe*). *Tremoctopus* attains considerable size and is widely distributed, occasionally being cast up on our southern beaches; it has a deep web between the upper three pairs of arms, perhaps of use in collecting plankton. *Argonauta* is discussed in the article Nautilus.

The free-swimming deepwater octopods show considerable modification. The gelatinous *Eledonella* and *Vitreledonella* are poor swimmers found from about 600 to 7,500 ft. They are widely distributed in the seas; a specimen of the former has been taken from a depth of 17,400 ft. A peculiar deep-sea form is *Cirrothauma murrayi*, which is blind. Like several other deep-sea genera, it is unusual among the octopods in the possession of elongate, paddlelike fins. The flapjack devilfish (*Opisthoteuthis*) is flattened and disclike, gelatinous, with the arms deeply involved in its web. It lives in the bottom ooze in many seas.

The shallow-water octopods (*Octopus, Eledone*) move by crawling about the bottom, or when alarmed, by shooting swiftly backward through the water by a jet of water from the funnel. These forms eject copious quantities of ink when they are en-

dangered, the ink being used as a screen behind which the animal slips away. In some species the ink paralyzes the sensory organs of the attacker. The common octopus has highly developed pigment-bearing cells and can change its colours to an astonishing degree and with great rapidity.

Octopods, which feed mainly upon crabs and lobsters, at times during years of exceptional abundance in England have been responsible for nearly destroying the lobster fishery. In turn they are fed upon by a number of marine fishes such as the cod.

Octopods have long been considered a great delicacy by peoples of the Mediterranean area who prepare them in many ways. They are fished for throughout the Mediterranean and the Caribbean, and are taken off California, Japan and in Oceania and the far east. When properly prepared the flesh is sweet, tender and demands a high price. *See* CEPHALOPODA; MOLLUSK.

See F. Lane, *Kingdom of the Octopus* (1957). (G. L. V.)

OCTROI, a tax levied by a local political unit, normally the commune or municipal authority, on certain categories of goods on their entry into its area. The institution of such tax in Italy goes back to Roman times, when it bore the title of *vectigal* or *portorium*, and in France to the 13th century. Suppressed in the latter country under the Revolution in 1791, the tax was reestablished five years later; and until the close of the first quarter of the 20th century it was operative very generally throughout the land. It was abolished in Belgium in 1870 and in Egypt in 1903; after World War II it still persisted in France, Italy, Spain, Portugal and Austria, but there was a marked tendency toward radical reduction in its total area of operation, or even its general suppression. The last octrois which had survived in France were suppressed from Jan. 1, 1949, by a decree of Dec. 9, 1948. Public opinion in France had been critical for generations of a tax system that was highly irksome, inconvenient in its mode of collection and unduly costly in relation to its yield (the levy process sometimes absorbed 50%). It was turned decisively against the system by the phenomenal increase of motor traffic.

O'CURRY, EUGENE (1796–1862), Irish scholar, an industrious copyist and translator of Irish manuscripts, was born at Dunaha, County Clare, in 1796. He examined and arranged many of the Irish manuscripts in the Royal Irish Academy and Trinity College library and compiled the catalogue of those in the British museum. In 1854 he was appointed professor of Irish history and archaeology in the new Catholic University of Ireland. His lectures, which give a full account of the medieval chronicles, historical romances, tales and poems, were published in 1861. Subsequent volumes entitled *On the Manners and Customs of the Ancient Irish* appeared in 1873. He died in Dublin on July 30, 1862. (A. CR.)

ODAENATHUS (or ODENATUS, latinized forms of Aramaic ODAINATH) (d. A.D. 267 or 268), the name of a famous prince of Palmyra who succeeded in recovering the Roman east from the Persians and restoring it to the empire. He belonged to the leading family of Palmyra, which bore, in token of Roman citizenship, the name of Septimius; earlier members of the family (probably of Arab descent) include two Roman senators, Septimius Odainath and Septimius Hairan, the latter (Odaenathus' brother or father) being referred to as "chief of the Palmyrenes" in A.D. 251. The year when Odaenathus became chief of Palmyra is not known, but already in an inscription dated 258 he is styled by Palmyrenes *vir consularis* (*i.e.*, of consular rank) and "master."

The defeat and capture of the emperor Valerian (A.D. 260) left the eastern provinces largely at the mercy of the Persians. Odaenathus, apparently after a rebuff from the Persian king Shapur I, launched an offensive. He fell upon the victorious Persians who were returning home after the sack of Antioch, and before they could cross the Euphrates inflicted upon them a considerable defeat.

Then, when two usurping emperors were proclaimed in the east (261), Odaenathus took the side of Gallienus, the son and successor of Valerian, attacked the usurper Quietus at Emesa (Homs, in western Syria), and after Quietus' death was rewarded for his loyalty by the grant of an exceptional position (262).

Odaenathus may have assumed the title of king before; but he now became *corrector totius Orientis:* not emperor, but the emperor's extraordinary deputy in the east. In a series of rapid and successful campaigns, he crossed the Euphrates and relieved Edessa, recovered Nisibis and Carrhae (Harran) and even took the offensive against the power of Persia and invested Ctesiphon, the capital, itself; he probably also brought back Armenia into the empire. These brilliant successes restored the Roman rule in the east. There can be little doubt that Odaenathus aimed at independent empire; but during his lifetime no breach with Rome occurred. He was about to start for Cappadocia against the Goths who had invaded it when he was assassinated, together with his eldest son, Herodes, by his nephew Maeonius (or Odaenathus; ancient accounts vary).

After his death (267 or 268) his widow Zenobia (*q.v.*) succeeded to his position, and practically governed Palmyra on behalf of her young son Vaballathus or Athenodorus. *See* PALMYRA. (G. A. C.; X.)

ODA NOBUNAGA (1534–1582), Japanese general and statesman who was the principal agent in unifying Japan after the long period of feudal wars that had continued since the 14th century. He was the administrator of a fief near the present city of Nagoya, and conquered a consolidated bloc of territory across the waist of the central island of Honshu. He skilfully used the wealth of the rising merchant class to finance his conquests and to swell the coffers of the imperial house, for he expected imperial approval of a future unification of the country. In 1573 he deposed the shogun, thus ending the Ashikaga shogunate. In 1576 he built a magnificent castle at Azuchi as a monument to and administrative centre for his power. He gave protection and economic aid to the Jesuit missionaries who began to arrive in Japan in some numbers at this time. He may have done so partly because he admired them, but it is more likely that Nobunaga saw in Christianity a potential counterweight to the influence of the Buddhist temples. These temples were serious impediments to unification of the country, and Nobunaga is said to have destroyed several thousand of them in central Japan.

ODE, a ceremonious poem on an occasion of public or private dignity, in which personal emotion and general meditation are united. The Greek word *ōdē*, which has been accepted into most modern European languages, meant a choric song, usually accompanied by a dance. Alcman (7th century B.C.) originated the strophic arrangement of the ode, and Stesichorus (640–555 B.C.) invented the triadic structure of strophe (*q.v.*), antistrophe and epode which characterizes the odes of Pindar and Bacchylides. Choral odes were also an integral part of the Greek drama, separating the action and commenting on the events of the plot (*see* DRAMA: *Greek Drama*). In Latin the word was not used until very late, and no Latin poet attempted to emulate Pindar, a task which Horace likened to Icarus' presumptuous flight. Horace's *carmina*, written in stanzas of two or four lines, are now universally called odes, and in literature after the Renaissance the word ought always to be qualified by the epithet Pindaric or Horatian. The aristocratic Greek, immediately celebrating athletic victories of noble youths with a public performance of choric songs of elaborate complexity and passionate brilliance, and the bourgeois Roman, patient enough to spend seven years to perfect the phrasing of a short poem which would be read in private by a sophisticated friend, have nothing in common; and it is unreasonable to expect much in common between the Pindaric and Horatian odes of modern literatures.

Pindar's challenge rather than Horace's caution proved acceptable to the Renaissance poets. Within 20 years of Aldus Manutius' first edition of Pindar's poems (1513), Luigi Alamanni (1495–1556) published his Italian imitations, but it was not until 1550, when Pierre de Ronsard published four books of *Odes* in French, that the form became established in the vernacular literatures. In Italy Gabriello Chiabrera wrote Pindaric odes on Ronsard's model, and in England the first signs of the fashion are to be discovered in the poetaster John Southern's *Pandora* (1584). In the 17th century Jonson, Milton, Thomas Randolph, Abraham Cowley, Dryden and Charles Cotton all wrote odes which, whether or not

they were entitled Pindaric, were more indebted to Pindar than to Horace. Of these Dr. Johnson considered Dryden's "To the Pious Memory of Mrs. Anne Killigrew" "undoubtedly the noblest ode that our language ever has produced." Modern taste would probably accept Dryden's own preference for "Alexander's Feast."

To the Augustan spirit of the next century Horace was more congenial, though many poets still attempted to soar with the Theban eagle, only to fall winged, as Horace had said they must. Thomas Gray alone achieved the Pindaric sublime in two famous odes, "The Progress of Poesy" and "The Bard." He was "consequently a little obscure," said Horace Walpole; but he showed the way to the romantics, for whom the liberty of the ode was most opportune. Wordsworth, Coleridge, Shelley, Tennyson, Patmore, Swinburne, Robert Bridges and others continued the tradition with impartial deference to Pindar or Cowley whose *Pindarique Odes* (1656), although irregular, had been among the first to establish the form in England. In France Victor Hugo, in Germany Goethe, Schiller and Hölderlin, and in Portugal Antonio Dinis da Cruz e Silva all testified to the vigour of the Pindaric type. Keats's odes ("To a Nightingale," "On A Grecian Urn," etc.) which are neither Pindaric nor Horatian, and which we call odes only because Keats is great enough to persuade us, have also been imitated.

Dominant as Pindar's influence has been, even from the 16th century poets have intermittently conceded the truth of Horace's judgment. Ronsard gave up attempting to rival Pindar, content to be, in his own opinion, Horace's better. Chiabrera followed his example, and also Bernardo Tasso's. But the Spaniards, Garcilaso de la Vega, Fernando de Herrera and Luis de León, were more consistent in their admiration of Horace and less inclined to venture on Pindaric flights. In England Michael Drayton was the first to produce a collection of odes in *Poems Lyric and Pastoral* (1606), in the preface to which he describes the kind and admits his principal debt to Horace. Jonson followed, and even when imitating the Pindaric triad his tone is Horatian. "The tribe of Ben" were as Horatian as their progenitor, but it remained for Andrew Marvell to write the finest Horatian ode in the language, "An Horatian Ode Upon Cromwell's Return From Ireland" (1650), in a four-line stanza which suggests, without reproducing, Horace's Alcaic stanza. In the Augustan age many imitated Horace, and with less risk than the imitators of Pindar: they neither rise so high nor fall so resoundingly. Matthew Prior was the most expert Horatian of the early 18th century, William Collins of the next generation, before romantic enthusiasm, disdainful of *aurea mediocritas*, was transported by the Pindaric. At the end of the 19th century Robert Bridges recovered something of Horace's polish; but the Epicurean urbanity of the Horatian ode is still further than the ardent nobility of the Pindaric beyond the grasp of the 20th century.

See also PINDARICS.

BIBLIOGRAPHY.—R. Shafer, *The English Ode to 1660* (1918); G. N. Shuster, *The English Ode from Milton to Keats* (1940); G. Highet, *The Classical Tradition* (1949). (E. J. M. BN.)

ODENDAALSRUS, a town of Orange Free State province, Republic of South Africa, lies 38 mi. S.W. of Kroonstad at 4,411 ft. above sea level. Pop. (1960) 15,047, comprising 6,070 Europeans, 8,861 Bantu, and 116 Coloureds. Although it obtained municipal status in 1912, Odendaalsrus remained little more than a village until 1946 when one of the world's richest goldfields was discovered near its boundaries. It grew rapidly in size and now contains modern buildings, including a town hall, schools, a hospital, a park and sports facilities. It is linked with the main railway line between Johannesburg and Cape Town. (HE. ST.)

ODENSE, the third largest town of Denmark, port and chief town of Odense *amtsraadskreds* (county council district), lies on the Odense river in a central position on Fyn (Fünen) Island about 175 km. (109 mi.) by road and ferry west of Copenhagen. Pop. (1960) 111,145. Near the town hall (rebuilt 1955) stands the Gothic St. Canute's (St. Knud's) cathedral (*c.* 1300), originally founded by him in the 11th century; his shrine and traditional tomb are in the crypt. There is a richly carved and gilded altarpiece (*c.* 1520). The castle (now the county administrative offices) was built by King Frederick IV in 1721 partly on the foundations of St. Hans' monastery which was built by the Order of St. John of Jerusalem together with St. Hans' church. The Greyfriars hospital in Jernbanegade, originally a Franciscan monastery, was founded in 1279. The home of Hans Christian Andersen, who was born at Odense in 1805, is now a museum; there are also an open air museum (the Fünen village) and museums of art, archaeology and history. The construction of a ship canal (1796–1804) linked the town with Odense fjord and increased its importance as a port. Odense is on the main railway from Copenhagen to Esbjerg and Germany and there is an airport at Beldringe. The town has electrical and machine industries, textile mills, breweries and shipbuilding. Agricultural products are exported.

Odense dates back to heathen times. The name is derived from *Odin's vi* ("Woden's Sanctuary"), but is first mentioned in history about A.D. 1000. King Canute was killed in front of the high altar in St. Alban's church in 1086. He was later canonized and his shrine became the resort of pilgrimages throughout the middle ages, the town thus becoming a religious and commercial centre.

ODENSE AMTSRAADSKREDS consists of the northern part of the island of Fyn. Pop. (1960) 207,273. Area 701 sq.mi. It consists chiefly of fertile arable land. The production of butter, cheese and bacon is important; there is also fruit-growing and sugar-beet cultivation. The towns have manufacturing industries, especially Odense. Lindo, on the firth of Odense, has a shipbuilding yard for ships up to 100,000 tons. (SV. L.)

ODENWALD, a wooded upland in Germany, 80 km. (50 mi.) long by 40 km. (25 mi.) broad, situated mainly in the *Land* (state) of Hesse, with small portions in Bavaria and Baden-Württemberg. A popular tourist area, it stretches between the Neckar to the south and the Main to the north and overlooks the Rhine valley to the west. Uplands of crystalline rocks, which are closely settled, lie in the western part, but most of it is an upland of horizontal sandstones covered with coniferous woods. It is bounded against the Rhine by fault scarps comprising a rich and densely settled strip called the Bergstrasse ("mountain street"). The highest points are the Katzenbuckel (2,054 ft.), Neunkircher Höhe (1,985 ft.) and the Krähenberg (1,821 ft.). The wooded heights overlooking the Bergstrasse are studded with castles and medieval ruins.

The Odenwald, the hunting ground of the Nibelungs, was the background for the epic poem *Nibelungenlied* (*q.v.*), according to which Hagen slew Kriemhild's husband at the well (a popular point of interest to tourists). The *Nibelungenstrasse* cuts across the Odenwald from west to east between Worms and Würzburg and though marked for tourists, is certainly not accurately placed. Another legendary figure is the "Wild Huntsman of Rodenstein" (popularized by Joseph Victor von Scheffel) who supposedly galloped with fearful din to Schnellerts castle. (R. E. D.)

ODER (Czech. and Polish ODRA; ancient VIADUA), a river of Europe, 567 mi. long, which rises in the Carboniferous rocks of the Oder mountains, Czech. After flowing southeast, it bends northeastward and then northwestward to enter the Silesian plain. There, the river widens into a broad valley with low banks and cuts through Recent deposits. In its lower course it has a branched channel with its main course flowing past Szczecin (Stettin) into the Oder Haff (Zalew Szczecinski or Stettin lagoon), which is connected with the Baltic sea by three arms, the Peene, Swina and Dziwna (Dievenow), joining the islands of Usedom (Uznam) and Wolin (Wollin). The Swina is the main channel for navigation.

The Oder enters Poland north of Ostrava and skirts the western side of the Upper Silesian coalfield. It receives a number of left bank tributaries from the gneisses and granites of the Bohemian massif, the chief being the Kłodzka, Kaczawa (Katzbach), Bóbr (Bobrawa), and the Lusatian Neisse (Nysa Luzycka); but the major part of the drainage basin lies to the east and the biggest affluents are those on the right bank, the Warta with its tributaries the Notec and Obra, the Mala Panew and Barycz. Between the confluence with the Neisse and a point near Gryfino south of Szczecin, the Oder forms the frontier between Poland and the

German Democratic Republic. The drainage basin of the river lies almost entirely in Poland and covers more than one-third of the country.

The principal towns on the Oder's banks are Raciborz, Opole, Brzeg, Wroclaw (Breslau), Glogow (badly damaged in World War II), Frankfurt an der Oder, Kostrzyn, Szczecin and Swinoujscie. The river forms an important highway into the German Democratic Republic, Poland and Czechoslovakia, and communist plans envisage it as a major artery for heavy industrial traffic, linking the Moravian and Upper Silesian economic regions with Szczecin and the east-west canal systems of the Spree, Mittelland and Notec-Vistula. The inter-war partition of the Upper Silesian coalfield handicapped mineral traffic via the Oder, which is linked to the western part of the coalfield by the Gliwice canal (25 mi.). The establishment of unified Polish control over the coalfield and the Oder river in 1945 stimulated investment in improvements and extensions to the navigable system; a canal, linking the upper Oder and Vistula rivers, and the building of many factories along its banks were projected. In 1958 a long-term project for linking the Oder with the Danube via the Moravian gate was agreed between Poland, Czechoslovakia and the German Democratic Republic, under which the Oder was to be made navigable throughout for 1,000-ton barges by 1970, with traffic on the river estimated to reach 5,000,000 tons by that year. Hitherto the river had been navigable for barges only as far as Raciborz, where it is about 100 ft. wide.

Growing industrial demand for water has contributed to rapid industrialization alongside the Oder. Among major industries are fertilizers at Kedzierzyn, cement around Opole, a chemical combine at Brzeg producing phenol and chlorine, copper south of Glogow based on large and recently proved deposits, and extensive brown coal working in Zielona Gora *wojewodztwo* (province). At Szczecin important shipyards were reconstructed and built between 1945 and 1960. The port of Szczecin developed rapidly, by 1958 handling two-thirds of total Polish transit turnover, principally with Czechoslovakia, the German Democratic Republic and Hungary. By the early 1960s, with a total turnover of more than 8,000,000 tons of cargo, it handled the greatest volume of any Polish port. (Ed. Br.)

ODESSA, an *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., formed in 1932, lies between the Black sea (south) and the Moldavian S.S.R. (west), and between the Rumanian frontier on the Danube delta and the Tiligul lagoon (Tiligulski Liman). Area 12,780 sq.mi. Pop. (1959) 2,027,807. The *oblast* is divided by the Dniester estuary which lies across its narrow "waist." The southwest is coastal plain, sloping gently to the Black sea. This part up to 1954 formed the separate Izmail *oblast*. The northeastern part extends farther inland, occupying the western half of the Dniester–Southern Bug interfluve, and reaching the southern hills of the Volyno-Podolsk upland. The whole *oblast* lies within the steppe and is marked by a dry climate. Rainfall ranges from 12 in. a year on the coast to 18 in. on the upland. The continental climate is much modified by the proximity of the sea, with January average temperatures −2° C. (28° F.) on the coast to −5° C. (23° F.) inland, and July averages from 23° C. (74° F.) on the coast to 22° C. (71° F.) in the north. There is little surface water and all but the largest rivers are liable to dry up in the summer. Soils are mostly fertile chernozems and little of the natural grass steppe remains unplowed. The whole coast is low, with long offshore bars enclosing lagoons in the drowned lower river valleys, most of which are rapidly silting up.

Of the 1959 population, 48% (964,159) were urban, living in 11 towns and 17 urban districts. More than two-thirds live in Odessa, the remaining urban areas being small. The most important are Izmail (48,103), Kotovsk (27,383) and Belgorod-Dnestrovski (21,832). Industry is chiefly concentrated in Odessa, but food processing is widespread in the smaller towns, based on an intensive agriculture. Grains dominate the arable with nearly 70% of the sown area. Winter wheat, maize (corn) and barley are the chief crops. Sunflowers are the main industrial crop, with sugar beet important in the uplands and some flax, hemp and mustard. Vegetables, especially melons, are widely grown, and are intensively cultivated in the market gardening area around Odessa. In the southwest there are vineyards and orchards, with Bolgrad as the chief wine centre. Livestock husbandry is well developed, with dairy and beef cattle in first place but also large numbers of sheep including karakul. (R. A. F.)

ODESSA, a seaport and *oblast* administrative centre of the Ukrainian Soviet Socialist Republic, U.S.S.R., stands on a shallow indentation of the Black sea coast, about 19 mi. N. of the Dniester estuary (Dnestrovski Liman); 275 mi. S. of Kiev. Pop. (1959) 667,182. Although there had been settlement on this site since ancient times (*see* Tripolye), the present town owes its origin to the establishment of a Tatar fortress (Khadzhibei) in the 14th century. After a period of Lithuanian-Polish supremacy, the fortress passed to Turkey (1764). In the Russo-Turkish War of 1774 it was stormed by the Russians and in 1791 was ceded to Russia. In 1792–93 a new fortress was built and in 1794 a naval base and commercial quay were established. In 1795 the new port was named Odessa after the ancient Greek colony of Odessos, the site of which was believed to be in the vicinity. During the 19th century it developed rapidly and by 1863 it was the third town of Russia, with 119,000 inhabitants. In 1866 railways reached Odessa and it expanded to 403,000 people by 1897. It was second in importance as a port to St. Petersburg and Russia's major grain-exporting port. Odessa was one of the chief centres of the 1905 uprising and the scene of the mutiny of the warship "Potemkin." After the Revolution, Odessa underwent a number of conflicts and was several times occupied by foreign troops before Soviet power was finally established. During World War II much damage was suffered in the prolonged defense against German and Rumanian troops and in the subsequent occupation and liberation. (While occupied it was made the capital of Transnistria [Rumanian zone of administration].)

Although modern Odessa has lost some of its relative importance it is still a major industrial centre and port. Among its engineering products are machine tools, cranes, winches, tractor parts, plows, cinematic apparatus, gas generators, mining equipment, printing and refrigerating machinery and weighing machines. There are ship repair yards, and superphosphate fertilizers, clothing, jute bags, leather goods and foodstuffs are also made. The port, one of the largest in the U.S.S.R., is well equipped to handle a range of cargoes. After 1957 a new port was constructed at Ilyichevsk, 15 mi. S. There is a fishing fleet and it is the base of the Soviet Antarctic whaling fleet. Odessa has good rail communications to Cherkassy and central Russia, to Khmelnitski and the western Ukraine, to Kishinev and Rumania and to Izmail.

Odessa is a cultural centre, with the I. I. Mechnikov State university (1865), the Filatov Institute of Eye Diseases, other higher educational establishments and many technical and specialist schools. There is a theatre of opera and ballet and several other theatres and museums. (R. A. F.)

ODESSA, a city of western Texas, U.S., is on the southern high plains 45 mi. S.E. of the southeastern corner of New Mexico and is the seat of Ector county.

One of the largest known meteor craters in the United States is located a short distance south of Odessa. It is more than 600 ft. in diameter and more than 150 ft. deep.

In 1881 the site was named for Odessa, Russia, by railroad construction workers who noted the similarity of the region to their Russian homeland. The town was established in 1886 by German wheat farmers from the north, but the county was devoted entirely to ranching when it was organized in 1891. Incorporated in 1927, the city adopted a council-manager form of government in 1946.

Oil was discovered in the late 1920s, and, with the establishment of the petroleum and related industries, the town's population, which was less than 3,000 in 1930, increased more than twentyfold in 30 years. Pop. (1960) 80,338; standard metropolitan statistical area (Ector county) 90,995. (For comparative population figures *see* table in Texas: *Population*.) Located in the geographic centre of the Permian basin, one of the largest known oil reserves, Odessa is a major distribution and servicing point for the petroleum industry. Manufactures include oil-field equipment, petroleum

products, synthetic rubber, cottonseed oil, chemicals and tile. Large deposits of carbon black, potash, salt, limestone and potassium are also mined and processed in the vicinity. Stock and poultry raising are also carried on. Odessa junior college (1946), located within the city, is municipally controlled. For the geography of the region *see* LLANO ESTACADO. (E. WE.)

ODIN (ÓðINN), one of the principal gods in Scandinavian mythology. The picture of him, however, which results from the wealth of sources, both literary and archaeological, is so complex that it is difficult to determine his role and nature exactly. The Roman historian Tacitus states that the Teutons worshiped Mercurius; and, if only because of the identity of *dies mercurii* (Mercury's day) with Wednesday (Woden's day), there can be little doubt that the god Woden whose name was the earlier form of Odin is meant. He is worshiped preeminently. There is corroborative evidence of this cult, but not sufficient to show whether it was practised by all the Teutonic tribes or to enable conclusions to be drawn about the nature of the god. Literary sources, largely aristocratic in character, give the impression that much later, at the end of the heathen period, Odin was the principal god in Scandinavia; but it is not certain that this was always so. Thor (Þorr) is also very prominent, and it is Tyr (Tiw) whose name is etymologically related to Zeus-Jupiter. Some scholars have even denied that Odin is autochthonous, although it

ANTIKVARISK TOPOGRAF.SKA ARKIVET BY COURTESY OF THE STATENS HISTORISKA MUSEUM, STOCKHOLM

DETAIL OF A PICTURE-STONE FROM GOTLAND, ABOUT A.D. 800, SHOWING ODIN RIDING HIS EIGHT-LEGGED HORSE, SLEIPNIR

is difficult to explain his highly complex character by foreign influences. He also appears as one of a triad.

From the earliest times he was a war god, and he appears in heroic literature as the protector of heroes; fallen warriors go to him in Valhalla. The spear which he normally carries is probably as much a symbol of authority as a weapon; he rides an eight-legged horse, Sleipnir, and the wolf and the raven are dedicated to him. He was also the god of poets, and two versions exist of the story of how he stole the poets' mead; it has been suggested that this mead can be equated with the fluid represented in cosmological speculations as the source of life. Odin is the great magician among the gods and is associated with runes. In outward appearance he is a tall, old man, with flowing beard and only one eye. A wide-brimmed hat covers part of his face, and he wears a cloak. In all his functions, including the martial, qualities of mind are prominent.

See also GERMANIC MYTHOLOGY AND HEROIC LEGENDS: *The Gods*. (K. C. K.)

ODO OF BAYEUX (*c.* 1036–1097), earl of Kent, half brother of William the Conqueror, who gave him the bishopric of Bayeux in 1049, was the son of Herluin of Conteville by Arlette, who had previously been mistress of Robert I, duke of Normandy. Ambitious and energetic, scandalously immoral, Odo had a many-sided career. As bishop he typified the pre-reform age of the Norman church, when the great churchmen were essentially scions of the aristocracy placed in possession of the church's wealth. Yet he spent lavishly on the building of his cathedral, created its capitular organization, and gave financial help to young students. It is likely that the Bayeux tapestry was commissioned by him, probably for the dedication of his cathedral (1077). Odo was active in the invasion of England, fighting in the battle of Hastings (1066). In 1067 he was made earl of Kent with special responsibility for guarding the southeast. He shared with William Fitz-Osbern and Geoffrey, bishop of Coutances, the task of ruling England in the king's frequent absences. In 1082 he was tried and imprisoned on a charge of raising troops without royal permission, probably to form a private army to defend the pope against the emperor Henry IV, though he was said later to have aspired to the papacy himself. Released on the accession (1087) of William II, he soon rebelled (1088) in support of Robert Curthose, duke of Normandy, and though the revolt was crushed Odo was allowed to join Duke Robert whose right-hand man he became. He was foremost in the movement leading to the first crusade and was at Palermo on his way to the Holy land when he died in Feb. 1097.

See F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (1947), and (ed.) *The Bayeux Tapestry* (1957). (G. W. S. B.)

ODOACER (*c.* 433–493), the first barbarian king of Italy, reigned from 476 to 493. The son of one Idico or Edeco, he is said to have belonged to the nation of the Sciri, though some say that he was a Rugian. In either case he was a German. A glorious future was foretold for him by St. Severinus in 470, when he was 37 years of age. He wandered in company with the Sciri to Italy about that date and eventually, along with the remnants of several other barbarian peoples who had been uprooted from their homes in the confusion which followed the fall of Attila's empire, he entered the service of the emperor Anthemius. But these barbarian troops supported Ricimer in overthrowing Anthemius, and they also supported Orestes in overthrowing the emperor Julius Nepos. As a reward for their support Orestes promised them a share in the senatorial estates of Italy, and when he did not carry out his promise, they revolted against him under Odoacer's leadership. Odoacer stormed Ticinum (Pavia), where Orestes had taken refuge, and finally captured and executed him in Placentia (Piacenza) on Aug. 28, 476. Odoacer then deposed Orestes' son Romulus Augustulus and allowed him to live in Campania. His army, which was composed of troops of several nations, had proclaimed Odoacer as king on Aug. 23. His aim now was to keep the actual administration of Italy in his own hands, while recognizing the country as being under the overlordship of the emperor at Constantinople. Accordingly, in 477 he sent a deputation of senators to Zeno at Constantinople asking for the rank of patrician and requesting that he be entrusted with the government of Italy. Zeno granted the first of these requests but asked Odoacer to acknowledge as emperor Julius Nepos, who was still living in Dalmatia. This Odoacer refused to do, but he did recognize the overlordship of Zeno himself; and in fact Nepos was killed on May 9, 480.

The senate at Rome supported Odoacer, and members of the leading aristocratic families received high honours and offices from him. Although he allowed the city prefect to hold his post only for one year so as to prevent any prefect from gaining too much prominence, Odoacer introduced few changes of importance into the administrative system in Italy. The distribution of estates to his Germanic followers—the matter which had led them to revolt against Orestes—was carried through apparently without serious opposition. There was unrest, however, among them in 477 and 478, and two counts named Bravila and Adaric are known to have lost their lives; but from the later period of the reign no such disturbances are known.

The church was little affected by Odoacer's rule. He himself was an Arian, and rarely intervened in the affairs of the Catholics. As for foreign politics, he had entered Dalmatia after Nepos' assassination there but did not succeed in crushing opposition until 482. In 484 the usurper Illus begged Odoacer's help in his struggle with Zeno. Odoacer refused, but nonetheless attacked the Il-

lyrican provinces in Illus' support; and Zeno incited the Rugi, who lived between Linz and Vienna, to attack Italy so as to distract him. Hence, in the winter of 487–488 Odoacer crossed the Danube and defeated the Rugi in their own territory, taking prisoner their king, Feletheus, and his wife, Giso, whom he executed in Ravenna. In a later campaign he defeated their son and thus put an end to Rugian power. Feeling himself insecure on the Danube, he ordered his brother Onoulf to evacuate the Roman provincials who lived there and bring them to Italy. The Visigothic king Euric, who had occupied much of Spain and Provence, including Arles and Marseilles, attempted an invasion of Italy but was repulsed by Odoacer's generals. But Euric retained some of the territory which he had overrun, and Odoacer's northwestern boundary was now formed by the Ligurian Alps. On the other hand, he recovered Sicily (apart from Lilybaeum) from the Vandals in return for an annual tribute.

For the circumstances of the invasion of Italy by Theodoric and the Ostrogoths and the campaigns of 489–493, in which Odoacer put up a stubborn and at times successful resistance to the invaders, *see* THEODORIC. When Ravenna, Odoacer's last stronghold, was finally surrendered to the Ostrogoths, Theodoric treacherously slew him there with his own hand on March 15, 493. His relatives and supporters were killed on the same day.

ODONATA, an order of insects comprising the dragonflies and damselflies. *See* DRAGONFLY.

O'DONNELL, a name of great prominence in the history of Ireland, especially from the 13th to the 16th century. There are five distinct clans or septs of O'Donnell. Four of these are of comparatively minor importance, but that of Tir Conaill (Tyrconnell), is outstanding. *The Annals of the Four Masters* (a compilation of materials on Irish history) mention no fewer than 201 individual O'Donnells of the Tyrconnell clan; there are only four entries for the O'Donnell sept of Corcabascin in west Clare, three for the Idrone (Leinster) family, and one for that of Ui Maine (Hy Many). All these, however, are still found in considerable numbers in the localities in which they originated.

In the northwest O'Donnell was the name of a powerful group of families, lords of Tyrconnell (all County Donegal except the promontory of Inishowen) from the beginning of the 13th century when Eighneachan, the first O'Donnell chief of note, wrested that territory from the O'Cannanains, later extending their sway over Inishowen, Fermanagh, part of Cavan and the northern part of Connaught (Connacht). As a clan they were known as Clann Dalaigh, from Dalach (d. 868), an early ancestor. The surname was derived from his 10th-century descendant Domhnall (Donnell) but their descent, like that of O'Neill of Tyrone, is traced from Niall Naoighiallach, of the Nine Hostages, king of Ireland at the beginning of the 5th century.

During the period of almost continuous warfare in the middle ages, the second outstanding chief of the name was Gofraidh (Godfrey), son of Donnell Mor O'Donnell (d. 1241), who, inaugurated chief in 1248, consolidated the position won by Eighneachan and died in 1258 of wounds received at the battle of Credran (1257), which was a decisive victory over their great rivals the O'Neills. Also important was Aodh Ruadh (Hugh Roe) O'Donnell (1427–1505), who as far as possible avoided war with the earl of Tyrone and often worked in alliance with James IV of Scotland and is remembered as the founder of the monastery of Donegal, which was later the scene of the labours of the Four Masters.

He was succeeded by another Hugh (d. 1537), called both Hugh Dubh or Duv (*dubh*, "black") and Hugh Og (*óg*, "young" or "junior"), who also enjoyed a long reign. He went on a pilgrimage to Rome in 1510, returning two years later to resume his leadership unchallenged, itself a sign that his father's policy, which he continued, had borne fruit. Intermittent warfare with the O'Neills could not be avoided, though O'Donnell's decisive victory over Conn O'Neill at Knockavoe in 1522 secured his position for a considerable time. In the time of Hugh Dubh's son, Manus O'Donnell (d. 1563), the English conquest of Ireland really began to be undertaken seriously and the first steps were taken toward national resistance. Reluctance on the part of the O'Neills and their ancient enemies the O'Donnells to form a strong combination greatly weakened opposition to the English, who were skilful in taking advantage of this situation, while the O'Donnells, like the other great chiefs, sought to make use of the English in their own interests when it suited them. The summary execution in the Tower of London of Silken Thomas, 10th earl of Kildare, and his five uncles in 1537, consolidated the opposition to Henry VIII. The remaining heir to the earldom was Gerald, a boy of 12 who was secretly in the charge of his aunt, Lady Eleanor MacCarthy. She married Manus, who in that year was inaugurated the O'Donnell, *i.e.*, chief of the clan, thereby securing a powerful protector for the boy. Gerald was, moreover, related to Conn O'Neill and the formation of the Geraldine league followed, the ultimate aim of which was the complete overthrow of English rule in Ireland. Though several of the principal chiefs went to England to submit to Henry VIII, Manus did not accompany them, but in 1541 he made terms at Cavan with Sir Anthony St. Leger who, presumably without any bias in his favour, commented on his elegant bearing and attire. The Four Masters, whose connection with the O'Donnells must not be forgotten when considering their eulogies, call him "a learned man, skilled in many arts, gifted with a profound intellect." Though he did not himself write the *Life of St. Columcille*, he caused it to be written.

Calvagh O'Donnell (d. 1566), the next chief, held the position officially for only three years, though in practice he ruled from 1555, when he deposed his father with the aid of the MacDonnells. His half brother, Hugh MacManus, took his father's side and enlisted the help of his cousin Shane O'Neill. O'Neill's invading army was defeated in 1557 by Calvagh, whose overlordship of Tyrconnell was then recognized by the English government. Shane got his revenge in 1561; he captured Calvagh and his wife and held them prisoners under extremely brutal conditions for three years. When at length Sir Henry Sidney intervened in 1566 to restore Calvagh, this benefited his son Hugh rather than himself, as he died a few months later and Hugh was duly inaugurated as chief of the name. Calvagh's son Con, who might possibly have succeeded, though primogeniture was not mandatory in the Gaelic system, was at the time a prisoner in the hands of Shane O'Neill. Hugh was now in a position to resume the traditional struggle with the O'Neills, in which of course he had the tacit approval of Sidney. He routed Shane at Farsetmore near Letterkenny in 1567, which caused Shane to seek refuge with the MacDonnells of Antrim, who in revenge murdered him and thus terminated the career of one of the most outstanding though not the most admirable figures in Irish history.

Hugh abdicated in 1592 in favour of his eldest son Hugh Roe O'Donnell (1572–1602), known as Red Hugh, grandson of Manus by his marriage with Judith O'Neill. Hugh Roe has been described as the last of the old Gaelic kings. He was then only 20 years old and his previous experiences helped to make him an inveterate enemy of the English. When less than 16 years old he had been kidnaped by Sir John Perrot, the lord deputy, who, conscious of the O'Donnell family's connexions with the O'Neills, feared a dangerous combination against the English government. He was long imprisoned in Dublin castle, made an abortive attempt to escape in 1590 and was finally successful in Jan. 1592.

Red Hugh's first concern was to drive out the English sheriff and his company of undisciplined marauders who, despite promises, had come to Tyrconnell and occupied the monastery of Donegal, after expelling the friars. This he accomplished successfully. Two expeditions against Turlogh Luineach O'Neill followed. Red Hugh's exploits in 1594 have been exaggerated; but in 1595 and 1597 he certainly turned his attention again to the west, making good his control of Connaught from Sligo to Leitrim. These, however, were minor operations compared with the war which followed, famous for the great Irish victory of the Yellow ford in 1598, where O'Donnell played a major part, and for the disaster of Kinsale (Dec. 1601). O'Donnell's march to join Tyrone at Kinsale was remarkable; in 24 hours he and his men covered no

less than 40 mi. including the almost impassable Slieve Phelim mountains. Red Hugh's support of the Spanish commander, Juan del Aquila, who counseled an immediate attack against the advice of the more cautious O'Neill, may well have brought about the crushing defeat that may be regarded as the death blow of the old Gaelic Ireland. O'Donnell then went to Spain where he died, said to have been poisoned by an English agent, though this has never been fully proved.

Meanwhile his cousin and brother-in-law Niall Garve O'Donnell (1569–1625) had gone over to the English. Though Hugh had delegated his authority to his younger brother Rory when he left for Spain, Rory was never inaugurated in his place. After Hugh's death Niall Garve, who had meanwhile quarreled with the lord deputy, was chosen chief by his own partisans. He did not long enjoy his position as he was charged with complicity in Sir Cahir O'Dogherty's rising of 1608 and imprisoned in the Tower of London, where he died.

Rory O'Donnell (1575–1608) accompanied Hugh to Kinsale. In 1603, having already signified his allegiance to Lord Mountjoy, the lord deputy, he went to London with Tyrone, and James I created him earl of Tyrconnell. The government's terms for a settlement satisfied neither Niall Garve nor Tyrconnell; Niall Garve's career was soon terminated and Tyrconnell began negotiations with Spain, which led to his sudden departure with Tyrone from Ireland in Sept. 1607, an event known as "the flight of the earls." Tyrconnell went to Rome and died three months afterward. His daughter Mary Stuart O'Donnell (b. 1607) was the heroine of many romantic and dangerous adventures. Rory O'Donnell was posthumously attainted in 1614 thus bringing more than 100,000 ac. in Ulster to the crown; but his son Hugh Albert was recognized by the court of Spain, where he lived, as earl of Tyrconnell.

Hugh Albert is supposed to have appointed Hugh Baldearg O'Donnell as his heir, but this is improbable. Hugh Albert died in 1642 and Hugh Baldearg lived until 1704. The latter fought with distinction for James II at the Boyne and at Aughrim, but later quarreled with Richard Talbot, earl and titular duke of Tyrconnell, and went over to William III. He did not remain in that service but returned to Spain and, taking part in campaigns in Italy and Austria, rose to high military rank. He was great-grandson of Con Mac Calvagh and from his line are descended the Larkfield O'Donnells. The chief of the name in 1962 was John O'Donel of Monkstown, County Dublin, of the Larkfield branch, and the presumptive successor to the title the duque de Tetuán, the next senior branch of the name. The 1st duque de Tetuán was Leopoldo O'Donnell (1804–67) who became a field marshal and grandee of Spain and was several times a prominent member of the government. There were also branches of the clan in Austria, the best-known individuals being Gen. Graf Karl O'Donnell (1715–71) of the Larkfield line. Gen. Daniel O'Donnell (1666–1735), great-grandson of Hugh Dubh of Ramelton, was another notable soldier; he led a regiment of the Irish brigade against the duke of Marlborough at Oudenaarde and Malplaquet. Other notable bearers of the name were James Louis O'Donnell (1738–1811), a Franciscan, known as the apostle of Newfoundland; John Francis O'Donnell (1837–74), poet and Fenian propagandist; and Patrick Cardinal O'Donnell (1856–1927), archbishop of Armagh. *See* also IRELAND: *History*.

See E. MacLysaght, *Irish Families* (1957), and *More Irish Families* (1960), which include bibliographies. (E. A. MacL.)

O'DONNELL, LEOPOLDO, CONDE DE LUCENA and DUQUE DE TETUÁN (1809–1867), Spanish general and politician, a loyal supporter of Isabella II, was born at Santa Cruz de Tenerife on Jan. 12, 1809. He made his name by his successful campaigns against the Carlists in the 1830s. He went into exile in France with María Cristina I (*q.v.*) in 1840 and helped to overthrow the Spanish government headed by Gen. Baldomero Espartero (*q.v.*) in 1843. He served in Cuba from 1844 to 1848 and then returned to Spain to become minister for war. In this post he shared control of affairs during the so-called *bienio progresista* (1854–56) with Espartero, whom he displaced as premier in July 1856, having formed a supporting group of dissidents known as the Unión Liberal. He led the administration only until October, but returned to power from 1858 to 1863. During this ministry he took command of the victorious expedition to Morocco (1859–60) which captured Tetuán. O'Donnell was rewarded with the title duque de Tetuán. He resumed office briefly in 1865–66; but though he was severe in repressing the San Gil rising (June 1866) he was not so harsh as the queen wanted and had to hand over his authority to Gen. Ramón María Narváez. He then retired to Biarritz, where he died on Nov. 6, 1867. O'Donnell enjoyed great personal popularity as a result of his successful African campaign, but his administration was marred by his lack of political ability and the absence of any clear political program.

See M. Ibo Alfaro, *Apuntes para la historia de D. Leopoldo O'Donnell* (1868).

ODONTOGLOSSUM, a genus of more than 100 species of showy, tropical-American, tree-perching (epiphytic) orchids; over 30 are grown in greenhouses for their unusual flowers. *O. grande* (the so-called baby orchid) of Guatemala and *O. crispum* of Colombia have flowers three to six inches wide in handsome clusters. With their many hybrids these are among the showiest, best-known and most easily grown of all orchids. (N. Tr.)

ODORIC (*c.* 1286–1331), Franciscan friar, traveler and a *Beatus* of the Roman Catholic Church who spent three years in China, was born about 1286 at Villanova, a hamlet near Pordenone in Friuli. At an early age he took the vows of the Franciscan order and entered their house at Udine. Between 1316 and 1318 Friar Odoric was sent to Asia where he stayed until 1329. During these years there was a great extension of missionary activity.

His route to the east lay by Trabzon and Erzurum to Tabriz and Sultaniah, in all of which there were Franciscan houses, thence by Kashan, Yazd, Persepolis and the Shiraz and Baghdad regions to Hormuz on the Persian gulf; at the last, he embarked for India. He landed at Thana near Bombay about 1322. After visiting many parts of India, and possibly Ceylon, he sailed in a junk to Sumatra calling at several ports along the northern coast, to Java, to the coast of Borneo (possibly), to Champa (south Cochin China) and to Canton.

He traveled extensively in China and visited Hangchow (Cansay, Khanzai or Quinsai, *i.e., Kingsze* or royal residence), then renowned as the greatest city in the world (he included many details about its splendours in his narrative). Continuing northward, he crossed the Yangtze, embarked on the Grand canal and traveled to Peking (Cambaluc). He stayed for three years in Peking, and was possibly attached to one of the churches founded by the archbishop Giovanni di Monte Corvino.

Returning to Europe by way of central Asia, Odoric seems to have journeyed through Tibet, possibly visiting Lhasa. Thereafter, he appears to have traveled to northern Persia, to Millestorte, once famous as the land of the assassins in the Elburz mountains, and thence, probably by way of Tabriz, to Venice. The account of the last stages of his homeward journey is vague and fragmentary. During at least a part of his long journeys Odoric was accompanied by Friar James, an Irishman.

Shortly after his return Odoric entered the Minorite house attached to St. Anthony's at Padua; there in May 1330 he related the story of his travels; his itinerary was taken down in simple Latin by Friar William of Solagna. Several months later while on his way to the papal court at Avignon, Odoric fell ill at Pisa. He was taken to the Franciscan house at Udine where he died on Jan. 14, 1331.

The fame of Odoric's journeys seem to have made a greater impression on the laity of Udine than on his Franciscan brethren. The latter were about to bury him, when the chief magistrate (*gastald*) of the city interfered and ordered a public funeral. Odoric's body was buried in the presence of the patriarch of Aquileia and other dignitaries. Popular acclamation made him an object of devotion and the municipality erected a shrine for his body. Although his fame had spread far and wide before the middle of the 14th century, he was not formally beatified until 1755.

Numerous surviving copies of Odoric's narrative (of the original Latin text as well as of versions in French and Italian) show how quickly it became popular. The substance of Sir John

Mandeville's supposed travels in India and China were taken without acknowledgment from Odoric.

BIBLIOGRAPHY.—Of the many manuscripts of Odoric's narrative extant, the chief one is in Paris (Bibliothèque Nationale, Mss. Lat. 2584, fol. 118r.–127v., of *c.* 1350); it was first printed at Pesaro in 1513. The best editions are G. Venni, *Elogio storico alle gesta del Beato Odorico* (1761); H. Yule (ed.), *Cathay and the Way Thither*, vol. i, pp. 1–162 and vol. ii, appendix, pp. 1–42 (1866). (E. M. J. C.)

O'DUFFY, EOIN (OWEN) (1892–1944), Irish military leader, was born on Oct. 30, 1892, near Castleblayney, County Monaghan, Ire. He joined Michael Collins' Irish rebels in 1917, but was captured and imprisoned in Belfast as leader of a rebel division. After release, he rejoined Collins in 1921, became chief of staff (1921–22) and then general officer commanding the Irish Free State forces (1924–25). He was also chief commissioner of the Civic guard (1922–33) but was removed from that post by Eamon de Valera. O'Duffy then joined the opposition, which he helped weld into the United Ireland party with the avowed purpose of fighting communism; he became its president in 1933. During this period, he also headed the Blue Shirts, a fascist offshoot organization of the U.I. party with a one-time boasted membership of 120,000. O'Duffy, however, was a poor politician and the U.I. disintegrated under his leadership. He himself resigned in 1934. To revive his waning prestige, he recruited 1,400 volunteers who joined Francisco Franco's "holy crusade against bolshevism" in Spain in 1936. But the O'Duffy brigade lost heart after a taste of battle and returned home in disgrace after six months in Spain. With this fiasco, O'Duffy lost what was left of his prestige. He died in Dublin on Nov. 30, 1944.

ODUM, HOWARD WASHINGTON (1884–1954), U.S. sociologist best known for his studies of social problems of the south, was born on May 24, 1884, near Bethlehem, Ga. He was educated at Emory university, the University of Mississippi, Clark college (Ph.D., 1909) and Columbia university (Ph.D., 1910). After joining the University of North Carolina in 1920, he pioneered in the development of social science, founding and heading departments of public welfare and sociology, a research institute and the journal *Social Forces*. Odum did his first important work on the social life and folk culture of the Negro, using both sociological and literary materials. In *Rainbow Round My Shoulder* (1928) he achieved literary artistry. At Pres. Herbert Hoover's request, Odum and William F. Ogburn organized and edited the report *Recent Social Trends* (1933). In *Southern Regions of the United States* (1936) he developed regional analysis and theory as a contribution to the South's reintegration in national life. In public service he sought new standards in race relations, public welfare, higher education, regional planning and penal reform. His major avocation, the breeding of Jersey cattle, brought him a master breeder's award. Odum's last book was *American Sociology* (1953). His system of sociology is best presented in his text, *Understanding Society* (1947). He died on Nov. 8, 1954, in Chapel Hill, N.C. (R. B. V.)

ODYSSEUS, called ULIXES by the Romans and ULYSSES generally since, Homeric hero prominent in western literature and imagination. His characteristics are intelligence, experience and endurance, sometimes seen as low cunning and insensitivity. He was the son of Laertes and Anticleia (or of Sisyphus), the husband of Penelope, the father of Telemachus and a protégé of Athena.

In the *Iliad* Odysseus at the behest of Athena restores Agamemnon's authority and rallies the disaffected Greeks, who are already rushing to their ships (ii, 142–335; for synopses of *Iliad* and *Odyssey* see HOMER). When Agamemnon too has had enough, Odysseus points out that there is nothing for a hero to do but stay and fight (xiv, 85–87). The death of friends also must simply be endured (xix, 220–233). In the end Achilles too realizes that there is no alternative to battle and no recompense for death—his own or Patroclus'. Odysseus' realism is seen at its grimmest in the night raid on the Trojan camp (book x), where he acts as Diomedes' preceptor in stealthy butchery. In sum, Odysseus in the *Iliad* is the effective man of worldly wisdom.

In the *Odyssey* Odysseus is the taker of Troy and even more prominently the man of experience. Here is first mentioned his stratagem of the wooden horse (*see* TROY) and his being judged more worthy than Ajax (*q.v.*) of the arms of Achilles. Not that his unpleasant side is ignored; rather, a virtue is made of it. Odysseus' burglar-grandfather Autolycus gave him the significant name "Odysseus," meaning something like "giver of pain" (xix, 405–409), and Odysseus saved that name from oblivion by living up to it. His first deed on leaving Troy is to sack a city, whereupon he is roughly handled. Yet the alternative to city-sacking, as expressed in the affair of the Lotus-eaters, involves "forgetting one's home." Next, he advances from being "No-man" to announcing himself as "Odysseus"—"giver of pain"—by putting out the Cyclops' eye with a red-hot stake. One of the analogues suggested is that to be born is a Cyclopean adventure—to pass from anonymity to crying one's name in the teeth of a hostile universe. This seems to be a necessity, for when Aeolus suspends nature's contrariness, Odysseus becomes trustful for a moment, and homecoming is lost. The Laestrygones are the cannibal giants whom Odysseus does not defy, and who thereupon destroy his fleet. With Circe it is the show of force that turns her menace to balm. The adventure in the land of the dead suggests the pain that lies at the heart of things, and its value. The dead recognize Odysseus in terms of the pain he connotes, and the speech of Hercules, the most hostile-appearing shade of all, implies that pain, given and suffered, wins immortality itself. Odysseus next safely negotiates the Sirens and their temptation to hear about life rather than experience it. Scylla and Charybdis give the *Odyssey's* choice in its most schematic form: face certain trouble from the monster, or be swallowed by the maelstrom. (The same choice is present at the beginning of the poem: oblivion with Calypso "the Hider" or certain trouble on the sea.) The cattle and sheep of the Sun suggest days and nights—there are 350 of each. To court oblivion by eating them merely to avoid the pain of hunger is like consuming one's days in inactivity to avoid the pain of a life in which to act is to injure and be injured but not to act is not to know and be known. Odysseus, resisting the temptation to oblivion, acts. Good, mild king though he has been, only his willingness to kill his enemies and deceive his friends can put his kingdom to rights and keep his name alive.

The later tradition found this strong stuff. Pindar (*Nemeans*, 7 and 8) thinks Odysseus despicable and his defeat of Ajax a fraud. In Sophocles' *Ajax*, heroic intransigence confronts Odysseus' wisdom, as in the *Iliad;* in *Philoctetes* Odysseus and Neoptolemus remind one of Odysseus and Diomedes in book x of the *Iliad*. (Stories making this second pair partners in crime, like the murder of Palamedes [*q.v.*] or the theft of the Palladium [*q.v.*], suggest the same source.) In Euripides' *Hecuba, Troades* and *Iphigenia at Aulis* Odysseus is a ruthless politician; in his satyr play *Cyclops* Odysseus is a burlesqued sophist. Plato gives him credit for intelligence and at the same time condemns his Homeric career by making him at the end of the *Republic* choose an obscure life for his next existence. Odysseus is a villain in the *Aeneid*, as he is in Seneca's adaptations of Euripides. Dante puts Odysseus and Diomedes together in one flame in the *Inferno*. But not all versions of Odysseus were unfavourable. Archilochus, Theognis of Megara, the Stoics and Cynics, Cicero and Horace all admired him. So did Racine and Fénelon, followed by Giraudoux. Calderón de la Barca reformed, Tennyson romanticized and Hauptmann made a madman of him. In Shakespeare's *Troilus and Cressida* he is an enigmatic man of the world. In Joyce's *Ulysses*, as Leopold Bloom, the man of hostility becomes a man of peace, with a name fecund rather than predatory in its connotations. *See* also references under "Odysseus" in the Index.

OEBEN, JEAN FRANÇOIS (*c.* 1715–1763), influential French cabinetmaker of German ancestry, was born probably between 1715 and 1720. In 1751 he began to work under Charles Joseph Boulle (son of André Charles Boulle) in the Louvre, Paris; and in 1754 he became "joiner and cabinetmaker to the king." He died in Paris on Jan. 21, 1763.

Oeben's style marks the transition from Louis XV to Louis XVI.

His work is characterized by wood marquetry in various colours and by solid, elegant bronze mounts. He also produced furniture with secret compartments and mechanical devices. His masterpiece, now in Versailles, is the *bureau du roi*, a magnificent desk which he began in 1760 and which was finished by J. H. Riesener in 1769.

See H. Vial, A. Marcel and A. Girodie, *Les Artistes décorateurs du bois*, vol. ii (1922); and F. de Salverte, *Les Ébénistes français du XVIIIᵉ siècle*, new ed. (1953). (S. Gr.)

OECOLAMPADIUS, JOHN (1482–1531), German humanist, patristic scholar and the reformer of Basel, was born at Weinsberg in Württemberg. His German name was Hüszgen. After schooling at Weinsberg and Heilbronn, he studied at Heidelberg. He left in 1506 to become tutor to the sons of the elector palatine, but in 1510 became preacher at Weinsberg. In 1513 he resumed studies at Tübingen, where he came into closer contact with southern German humanism and acquired remarkable versatility in Greek, Latin and Hebrew, teaching Greek from a grammar of his own devising. In 1515 he moved to Basel and assisted in the production of Erasmus' edition of the Greek New Testament, later preparing the index to the Erasmian edition of St. Jerome. In 1518 while penitentiary at Basel he translated some disciplinary treatises of certain Greek Fathers. These became a dominant interest and in the next years he produced translations of works by Gregory of Nazianzus, Basil, John of Damascus and two major works, a translation of *Psegmata* (*i.e.*, selected works) by Chrysostom and the commentary on the Gospels by Theophylact. In 1518 through the influence of the humanists Willibald Pirkheimer and the brothers Bernhard and Konrad Adelmann he became cathedral preacher at Augsburg. His mystic leanings, his patristic studies, his scholarly temperament, led him to enter the Brigittine monastery at Altomünster in April 1520 but disillusion and his Lutheran sympathies, manifested in his *Canonici indocti* (1519) and *Judicium de Luthero* (1521), caused him to leave in 1522 and he took refuge for a time as chaplain to the Adullamite company ranged round Franz von Sickingen in the Ebernburg.

Oecolampadius returned to Basel where he worked for a time in the printing house of Andreas Cratander and in 1523 became lecturer and professor in the university (where he had taken his D.D. in 1518). His lectures to great audiences in three languages and his sermons at St. Martin's church soon made him the dominant figure in the city. From 1522 onward he was the loyal friend and ally of Huldreich Zwingli. He acquitted himself manfully in 1526 when at the disputation of Baden he had almost alone to defend the cause of the Reformation against a formidable Roman Catholic team. In 1528 the disputation at Bern was packed with reformers, and Oecolampadius characteristically preached "On the love of Christ for his Church." In the next years he delivered an impressive series of lectures and sermons on biblical books, some of which were published. In the eucharistic controversy, Oecolampadius was on the side of Zwingli and it was his contribution to provide patristic support in a series of writings of which the *De genuina verborum domini* (1526) was the most notable. At the colloquy of Marburg (*q.v.*) in 1529 he was paired with Luther in fairly amiable but inconclusive debate. Affairs came to a head in Basel early in 1529 and Oecolampadius took a leading hand in shaping the reforming ordinances which went out at Easter and which established the Reformation in the city. At the spring synod of the Basel churches in 1530 he preached a notable oration "De reducenda excommunicatione" in which he tried to offset the dominance of the magistracy after the Zürich pattern by proposing a church discipline in which pastors and lay elders also shared.

The years 1530–31 were much occupied with writing and disputing with Anabaptists, who were suppressed in the city. Oecolampadius loyally supported Zwingli's foreign policy and under the shock of the disaster of Cappel in Oct. 1531 his health gave way. He died on Nov. 23, 1531. He had married in 1528. Oecolampadius' pendulous nose, sallow complexion and black eyes gave scope for caricature, but his character and learning were respected even by his enemies. From an introverted dilettantist he emerged after 1526 as a real leader, never simply a tool of Zürich, bringing to the Basel Reformation his own stress on inward religion and on true churchmanship. He symbolizes that important appeal among the reformers not only to Scripture but to the "old Fathers." For portrait *see* article Reformation.

OEDIPUS, in Greek mythology, king of Thebes who unwittingly killed his father and married his mother. Homer tells how his mother hanged herself when the truth concerning their relationship became known, though Oedipus apparently continued to reign at Thebes until his death. In the post-Homeric tradition, most familiar from Sophocles' *Oedipus Rex* and *Oedipus Coloneus*, but doubtless shaped initially by the cyclic epics, there are notable differences in emphasis and detail.

The story is that Laius, king of Thebes, was warned by an oracle that his son would slay him. Accordingly when his wife, Iocaste (Jocasta; in Homer, Epicaste), bore a son, he exposed the baby on Mt. Cithaeron, first pinning his ankles together—hence the name Oedipus, "swell-foot"—to ensure that no one would save the child, if found, or perhaps to make it impossible for his ghost to walk. A shepherd took pity on the infant, who was adopted by Polybus, king of Corinth, and his wife and brought up as their son. In early manhood Oedipus was taunted by a drunkard concerning his parentage and visited Delphi to learn the truth. The oracle informed him that he was fated to kill his father and marry his mother, so he resolved never to return to Corinth.

Traveling toward Thebes he encountered Laius, who provoked a quarrel in which Oedipus killed him. Continuing on his way Oedipus found Thebes plagued by the sphinx, a fabulous winged monster, half-human half-leonine, who put a riddle to all passersby and destroyed those who could not answer (*see* Sphinx). Oedipus solved the riddle, and the sphinx killed herself. In reward, he received the throne of Thebes and the hand of the widowed queen, his mother, Iocaste. They had four children: Eteocles, Polyneices, Antigone and Ismene. Subsequently the whole truth came to light: Iocaste committed suicide, and Oedipus, after blinding himself, shunned the daylight in the palace, or (in Sophocles' version) went into exile, accompanied by Antigone and Ismene, leaving his brother-in-law, Creon, as regent. He met his end at Colonus near Athens, where he was swallowed into earth and became a guardian hero of the land. The curse which he laid on his undutiful sons culminated in the deaths of Eteocles and Polyneices (*see* Seven Against Thebes), and so was ultimately responsible for the death of Antigone. The dramatic highlights in Oedipus' story were portrayed in ancient art; his encounter with the sphinx has caught the imagination of some modern artists also (*e.g.*, J. A. D. Ingres).

There may be a hard core of historical truth in the legend of Oedipus, but it is impossible to isolate it from the elements of folk tale with which it has become fused. Oedipus appears in the folk traditions of Albania, Finland, Cyprus and Greece, where his story is still told in a version apparently uninfluenced by Christianity. In medieval times Judas rather oddly displaces Oedipus in the *Golden Legend* of Jacobus de Voragine and in the *Mystère de la passion* of Jean Michel and Arnoul Greban. In *Le Roman d'Oedipus*, an anonymous work of the 15th century, the sphinx becomes a cunning and ferocious giant. The ancient story has intense dramatic appeal; through Seneca the theme was transmitted to a long succession of playwrights including Corneille, Dryden and Voltaire. It has had a special attraction in the 20th century, motivating Igor Stravinsky's secular oratorio *Oedipus Rex*, André Gide's *Oedipe* and Jean Cocteau's *La Machine infernale*. There is, in fact, something archetypal in the Oedipus legend; but while it is easy to understand how Freud chose the term "Oedipus complex" to designate a son's feeling of love toward his mother and jealousy and hate toward his father (*see* Psychoanalysis), it must be observed that these are not emotions that motivate Oedipus' actions or determine his character in any ancient version of the story.

OEHLENSCHLÄGER, ADAM GOTTLOB (1779–1850), the leading figure of the "golden age" of Danish literature, was born on Nov. 14, 1779, in Copenhagen. A year later the family moved to the royal palace of Frederiksborg, where his father was keeper. The renaissance architecture, paintings and sculpture which surrounded him during his boyhood there gave his taste its classical trend, and harmony became the keynote of his poetic genius.

After leaving school, he tried acting (1797–99), and then began to study law, but neglected it for aesthetics and old Scandinavian literature. A prize-winning paper on replacing Greek by Old Norse mythology in modern poetry foreshadowed his own poetic practice. He began to publish poems and in the summer of 1802 *Erik og Roller*, a pastiche of an old Norse saga, was actually in the press, but Oehlenschläger destroyed the proofs after meeting Henrik Steffens (*q.v.*), a scientist, Norwegian by birth, who had returned to Copenhagen from Germany a champion of the new romanticism. As a result of his influence, Oehlenschläger published *Digte* (Dec. 1802; dated 1803), which inaugurated a new period in Danish literature. "Guldhornene" (Eng. trans., *The Gold Horns*, 1913), the ballad which set the keynote for the volume, was written after an 18-hour discussion with Steffens. In symbolic pictures it expresses the romantic ideas of history and nature, but its setting and characters are Norse. Oehlenschläger showed his epic grasp by discarding lyrical vagueness for sculptured outline. *Digte* also included "Sanct-Hansaften-Spil" ("A Midsummer Night's Play"), a lyrical drama of contemporary Danish life, combining literary satire with elevated poetic discourse on love and nature.

The success of *Digte* was confirmed by *Poetiske Skrifter* (two volumes, 1805), containing the lyric cycle on the life of Jesus Christ annually realized through nature, Oehlenschläger's most daring pantheistic poem, which was condemned by the Danish church; "Vanlundurs Saga"; and the drama "Aladdin," in which he depicts his own life, the lamp symbolizing intuitive poetic genius. In the same year, in recognition of his position as Denmark's greatest living poet, he received a government grant, allowing him to travel for four years in Germany (where he met the leaders of the romantic movement and visited Goethe), France and Italy. While abroad, he published *Nordiske Digte* (1807) which marked a break with Steffens and the Schlegels. Rebelling against the subjectivity of the ultra-romantics, he turned to history and mythology as the basis of his poetry. This is illustrated by the works included in the new volume: "Uthors Reise," an epic in five cantos on Thor's journey to Jothunhein; "Baldur hin Gode," a mythological drama on Balder the Good, written in a classical Greek style; and "Hakon Jarl," his first tragedy on a national hero. In the preface he hailed Goethe, Schiller and Shakespeare as his masters.

Oehlenschläger returned to Denmark in the autumn of 1809, and, settling in Copenhagen, was appointed professor of aesthetics there in 1810. During the 1820s he was fiercely attacked by J. L. Heiberg (*q.v.*), the leading critic of the younger generation of poets, and lost his position of undisputed supremacy. Despite this, his popularity increased, and in 1829 he was crowned with laurel in Lund cathedral by Esaias Tegnér. On his 70th birthday he was hailed as the "Adam of our Parnassus" by all the contemporary Danish poets. He died at Copenhagen, on Jan. 20, 1850. His *Erindringer* were published in 1850–51.

Oehlenschläger set the fashion in many literary kinds. His long series of plays includes *Axel og Valborg* (1810; English translation 1851) and *Hagbarth og Signe* (1815), two tragedies of unhappy love; *Coreggio* (1811; Eng. trans. 1846) and "Yrsa," conceived as a Greek tragedy, and forming the last part of the trilogy *Helge* (1814); and the chronicle plays *Tordenskjold* (1833) and *Dronning Margareta* (1834). In *Dina* (1842) and *Kjartan og Gudrun* (1849) he tried to follow the fashion of the time by portraying more complex characters. He had a vivid sense of dramatic situation but his plays are deficient in logical structure. He also wrote stories, again based mainly on themes from Norse legends. It is as a writer of ballads and epics that he excels, however. The romantic ballads of his youth, the two epic cycles of *Helge*—ballads linked by a narrative, a poetic *genre* of his own creation—stand comparison with those of Goethe and Schiller, and in *Nordens Guder* (1819; Eng. trans. *The Gods of the North*, 1845), an epic made up of a number of cantos in different metres, he competes with Homer: "The Homeric nature awoke my own, the Greek inspired me to the Northern."

His poetry cannot be classified as merely romantic: it shares the hellenist inspiration of Goethe, Winckelmann and Herder. He combines classical strength with romantic ardour and inspiration.

OENEUS, in Greek legend, king of Calydon, husband of Althaea and father of Meleager (*q.v.*); through them he is connected with the legend of the Calydonian boar. He is also independently connected with Hercules (*q.v.*), as the father of Hercules' bride Deianeira, whom he won from the river-god Achelous. Oeneus may have been originally a wine-god: his name is derived from the Greek word for wine. Moreover, according to one story, Dionysus was the real father of Deianeira.

(H. W. PA.)

OENGUS, SAINT (OENGUS MAC OENGOBANN, called THE CULDEE) (fl. 8th/9th century), an Irish monk associated with a movement that aimed at the reform of Irish monasticism and author of the *Félire*. The reformed monks called themselves "Fellows of God" (*Céli dé*, anglicized "Culdees"). What little is known about Oengus personally derives mainly from an Irish poem that is found in one manuscript of his *Félire*. He was a monk at Clonenagh in Leix, then became a pupil of Máel-Rúan of Tallaght near Dublin, who was prominent among the monastic reformers. Later Oengus founded his own church, Dísert-Oengusa in Leix. His feast day is March 11.

About the year 800 he composed in Irish his *Félire* (calendar) in 365 quatrains (one for each day of the year) with a prologue and epilogue. Under each day are listed the names of Irish and foreign saints, each with a conventional epithet or, occasionally, with some historical or legendary detail. The recitation of this and similar verse "calendars" both in Irish and in Latin was probably a form of devotion to all the saints, which seems to have held an important place in the liturgy of the early Irish church.

The Middle Irish *Saltair na Rann*, a versification of biblical history, was written by a later Oengus Céle Dé.

BIBLIOGRAPHY.—The *Félire* is ed. by W. Stokes, with Eng. trans. (1905). *See* also J. F. Kenney, *Sources for the Early History of Ireland*, pp. 471, 479–481, 736–737; J. Hennig, "Studies in the Literary Tradition of the *Martyrologium poeticum*," *Proc. R. Irish Acad.*, vol. 56 C, pp. 197–226 (1954). (L. BR.)

OENOMAUS, in Greek legend, the father of Hippodameia. His death was caused by Pelops. *See* PELOPS.

OENOTHERA, the generic name of the evening primroses and sundrops, several species of which are favourite garden plants. The genus, comprising about 150 species, is native to the new world and belongs to the evening primrose family (Onagraceae; *q.v.*). The common evening primrose (*O. biennis*) is often a troublesome weed both in North America and in Europe, where it has become naturalized; the form known as var. *grandiflora* is a showy plant, sometimes cultivated for its flowers. Other species grown in gardens are *O. missouriensis* and *O. speciosa*, the latter with white flowers, grading to pink. The genus acquired importance in connection with Hugo de Vries' observations, especially on *O. lamarckiana*, which led to his theory of mutations (*see* EVOLUTION, ORGANIC: *Theories of Evolution*).

OERSTED (ØRSTED), **HANS CHRISTIAN** (1777–1851), Danish physicist and chemist, the discoverer of electromagnetism, was born Aug. 14, 1777, in Rudköbing. He was graduated as a pharmacist from the University of Copenhagen in 1797, received gold medals for essays in aesthetics and medicine, and obtained the Ph.D. degree in 1799 for a dissertation on Kant's philosophy. After extensive foreign travel and lecturing, he became professor at the University of Copenhagen in 1806. He suggested establishment of the Technical University of Denmark and became its first president in 1829.

Oersted's first physical researches dealt with electric currents

and acoustics. For nearly 30 years he gave time to the compressibilities of liquids and gases. His most important contributions to chemistry were the preparation of metallic aluminum (1825) and the discovery of piperidine (1820). Influenced by a philosophical belief in the unity of the forces of nature, he made many attempts to show that chemical and magnetic forces, and light have common electrical bases. During an evening lecture in April 1820 he discovered that a magnetic needle is deflected by an electric current (*see* INSTRUMENTS, ELECTRICAL MEASURING). The fundamental importance of this discovery was rapidly recognized, and he was honoured as one of the great physicists of the age.

Oersted was an inspiring teacher and lecturer and wrote numerous popular articles. In 1824 he founded a society devoted to the spreading of scientific knowledge among the general public. Since 1908 this society has awarded an Oersted medal for outstanding contributions by Danish physical scientists. In 1937 the American Association of Physics Teachers established an Oersted medal awarded to eminent physics teachers. In 1934 the name "oersted" was adopted for the unit of magnetic field strength. Oersted died in Copenhagen on March 9, 1851.

See essays by Kirstine Meyer in *H. C. Oersted: Scientific Papers* (1920); T. W. Chalmers, *Historic Researches* (1952). (J. R. Ns.)

OERTEL, HANNS (1868–1952), German linguist known especially for his contributions to Sanskrit syntax, was born in Geithain, Saxony, on April 20, 1868. Educated in the United States (Ph.D., Yale, 1891), he taught successively at Yale, Basel, Marburg and Munich. He wrote on Vedic literature, on general linguistic problems and particularly on Sanskrit syntax, and for many years was one of the editors of the *Zeitschrift für vergleichende Sprachforschung*.

In his *Syntax of Cases in the Narrative and Descriptive Prose of the Brahmanas* (1926) Oertel followed the lead of Berthold Delbrück (*q.v.*), but his plans for further work in that direction were brought to an end by the destruction during World War II of his house, library and carefully catalogued references. His *Lectures on the Study of Language* (1901), although interesting, is considered outmoded. Oertel died in Munich on Feb. 7, 1952. (MY. F.)

OETA (modern OITI), a triangular mountain block in central Greece, an outlier of the chief dividing range. It consists mainly of a dissected limestone plateau, about 6,200 ft. high, with a summit of 7,060 ft., and carries woods of beech and oak, with fir and pine on the higher slopes. The northern face of the massif is formed by a straight escarpment overhanging the Sperkhios valley, but its southern slopes, of less resistant rocks, are more gentle and are much eroded by the headstreams of the Mornos river. The eastern edge, cut by ravines, overlooks the Pournaraki pass, beyond which rise the Kallidhromon mountains. In mythology Oeta is the scene of the death of Hercules. (WM. C. B.)

OFFA (d. 796), Anglo-Saxon king of Mercia (*q.v.*) from 757 to 796, is the central figure in English history in the second half of the 8th century. A civil war gave him the Mercian kingdom in succession to his cousin Aethelbald (716–757) who in his later years had been overlord of all the English peoples south of the Humber. The first part of Offa's reign was spent in the re-establishment of the Mercian supremacy. He was strongly resisted in several of the smaller kingdoms, notably Kent, but he succeeded in creating what was in effect a single state covering the whole country between the Humber and the channel. He treated the lesser kings of this country as his subjects, exacting their formal submission, insisting that their grants of land to their own retainers or to churches needed his consent, confirming their charters and requiring them to attend his court. He married one of his daughters to Beorhtric, king of Wessex (789), and another to Aethelred, king of Northumbria (792), thereby extending his direct influence beyond the Humber. His reign marks by far the greatest advance hitherto made toward the political unification of England.

His position was recognized on the continent. His younger contemporary Charlemagne, king of the Franks, regarded him as the outstanding English ruler of his time. Their relations were often uneasy and a personal dispute led to a suspension of cross-channel traffic shortly before 790. Its renewal was followed by a commercial treaty (796) which shows Charlemagne and Offa dealing with each other on equal terms. The closeness of their previous association is illustrated by a rumour current at Rome to the effect that Offa had proposed to Charlemagne the deposition of Pope Adrian I and the election of a Frankish churchman in his place. The pope himself disbelieved the story, but its circulation proves at least the reality of Offa's fame.

Offa, in fact, was on terms with Pope Adrian which enabled him to carry through a remarkable, if temporary, change in the organization of the English church. The archbishop of Canterbury, whose authority covered the whole of southern England, had his seat in the kingdom where Offa's political domination was most strongly resented. To free the churches of his own country from the control of an archbishop belonging to an unfriendly province, Offa in 787 induced Pope Adrian to send the pallium, which was the symbol of metropolitan authority, to Hygebeorht, bishop of Lichfield. It was certainly with Offa's good will, and probably at his request, that in 786 the pope sent two legates to England, who secured the acceptance of a program of reform by the clergy and nobility of both the northern and southern provinces.

It is probable that Offa used this unprecedented mission as a means of acquainting the Roman court with his design of creating an archbishopric of Lichfield. He may well have taken the same opportunity of securing the papal approval for the consecration of Egfrith, his son, as king of the Mercians which took place in 787 and is the first recorded ceremony of the kind in English history.

There still survives a memorial of Offa's effective power in southern England in the remains of the great earthwork known as Offa's dike which he caused to be drawn between his own kingdom and the Welsh tribes beyond his border. It was the object of the dike to draw a boundary line between English and Welsh settlements from the estuary of the Dee in the north to that of the Wye in the south. The line is not now continuous, partly because it has been worn down in the course of 12 centuries, but also because in forest country such as the Herefordshire plain the forest itself was regarded as a sufficient barrier. But on open ground and in the high places of the mountain zone its remains are most impressive. Its line is always drawn so as to command the country to the west and the trackways leading from Welsh into English territory. Throughout its course it shows the activity of a directing mind.

The most permanent achievement of Offa's reign was the establishment of a new form of currency composed of silver pennies bearing the king's name and title and also the name of the moneyer responsible for their quality. They are remarkable for a delicacy of execution and a refinement of portraiture which set the best examples apart from all other coins in the Old English series. Amid infinite varieties of design, the principles governing Offa's coinage were maintained by later kings, and until recent times there has never been any break in the continuity of the English currency since his day. His own attitude toward the currency as an advertisement of the royal dignity is shown by the issue of coins closely resembling his own in type, but bearing the name and portrait of Cynethryth his queen.

No contemporary account of Offa has survived, and the history of his reign is a collection of fragmentary references. The laws which he is known to have issued have long disappeared. There are no adequate materials for a picture of his character. He was a patron of learning and a notable benefactor to many churches, but his rule was arbitrary and he was ruthless to all who opposed him. What can be said is that he left a deeper impression on English history than any other king before Alfred.

OFFA OF ANGEL (fl. 4th century A.D.), a continental Anglian ruler, son of Wermund and ancestor of the Mercian royal house. The Old English poem *Widsith* refers obscurely to his victory in single combat by *Fifldor*, probably the Eider river. The Danish historians Saxo Grammaticus and Svend Aggesen elaborate

the story. In Wermund's old age, he was threatened by the Saxons, who suggested a decision by single combat of the kings' sons. Offa had up to then been speechless with shame because Keto and Wigo, sons of Wermund's governor of Schleswig, had broken the rules of single combat by together attacking the man who had slain their father; he now undertook to fight the son of the Saxon king and another champion at once. A much corrupted version of this story appears in the English *Vitae duorum Offarum*, which places the seat of Wermund not on the continent but at Warwick. It is probable that the Offa whose marriage to a lady of murderous disposition is mentioned in *Beowulf* is Offa of Angel: this story the *Vitae* transfer to his descendant, Offa of Mercia.

OFFALY (UABH FAILGHE), a county of the Republic of Ireland in the province of Leinster, covers 771 sq.mi. On the west it shares with several other counties the distinction of a boundary in the Shannon, but it consists mainly of a large yet not unvaried section of the central lowland, though its southwestern boundary runs for many miles along the main crest of the Slieve Bloom mountains. It is mainly a mixture of peat bogs and cultivable land composed of glacial drifts over Carboniferous beds: a feature of particular interest is the fine series of eskers, or grand ridges, notably at Clonmacnoise, an ancient monastic site near the Shannon and one of the greatest religious foundations in Ireland (*see* CLONMACNOISE). In all, seven-tenths of the county is improved agricultural land; the bogs generally cover a few square miles, interspersed with farmland, and two of them, at Ferbane in the west of the county and near Portarlington in the east, are used to feed peat-fired electric-power stations.

The county formed part of the ancient kingdom of Offaly which included portions of Tipperary, Leix and Kildare. There are many raths, and a chain of moats commanding passes of the bogs extended throughout the county. On the borders with Tipperary is an ancient causeway that presumably once led to a crannog or lake dwelling. The area was inhabited by O'Connors and was annexed to the crown upon title claimed by descent from Roger Mortimer, a marcher lord from Herefordshire, who had held sway there in the 13th century and in the adjacent kingdom of Ossory or Leix. Offaly was shired as King's county in 1556, named to honour Mary I's consort, King Philip of Spain. An elaborate plan for colonizing Leix and Offaly was adopted by the government under Mary, the natives being required to vacate two-thirds of the area. They resisted resolutely for the rest of the century, being subdued only in the general subjugation of Gaelic Ireland at the beginning of James I's reign.

Offaly is united with Leix under the same county manager but has its own county council meeting at Tullamore. Birr and Tullamore (*q.v.*) are urban districts. Edenderry is administered by town commissioners. The county is united with Leix to send five members to the *dáil*.

The population of the county was 51,533 in 1961. More than two-fifths of the people live in towns and villages. Of these the largest is Tullamore (6,243) which in 1833 replaced Philipstown (now Daingean) as the assize and county town. Tullamore has a worsted mill, malting plant, distillery and a bacon and sausage factory. Of the other towns some have seen a measure of industrial growth. Birr and Edenderry have footwear factories, Clara a jute mill and at Edenderry, on a branch from the Grand canal, there is also a furniture factory. There are several other smaller places, such as Banagher at one of the few crossings of the Shannon, which serve as small market towns with monthly fairs for stock.

Of the county's improved farmland, two-thirds is permanent pasture, one-fifth under crops and the rest used as meadow. Wheat is prominent, with over 20,000 ac. devoted to it annually. It is sold to mills, and barley is sold to maltsters, notably at Tullamore. The sale of cattle at the fairs is a main economic activity. The general standard of farming is good.

Tullamore and Clara are on a branch railway line from Athlone to Portarlington; in 1947 the line from Clara to Banagher was closed for passenger traffic. Motor transport serves the county and the canal still carries some cargo.

OFFENBACH, JACQUES (originally JACOB) (1819–1880), French, originally German, composer who created a type of light burlesque French comic opera known as the *opérette*, which became one of the most characteristic artistic products of the second empire. Born at Cologne on June 20, 1819, he was the son of a cantor at the synagogue there, Isaac Juda Eberst, who had been born at Offenbach am Main. The father was known as "Der Offenbacher" (*i.e.*, the man from Offenbach) and the composer was known only by his assumed name, Offenbach. Attracted by the more tolerant attitude in Paris to the Jews, Offenbach's father took him there in his youth and in 1833 he was enrolled as a cello student at the Paris conservatoire. In 1844, having been converted to Catholicism, he married Herminie d'Alcain, the daughter of a Spanish Carlist. In 1849, after playing the cello in the orchestra of the Opéra-Comique, he became conductor at the Théâtre Français. In 1855 he opened a theatre of his own, the Bouffes-Parisiens, which he directed until 1866 and where he gave many of his celebrated operettas, among them *Orphée aux enfers* (1858). He then produced operettas, at Ems in Germany and an opera-ballet in Vienna (*Die Rheinnixen*, 1864), returning in 1864 to Paris, where at the Variétés he produced his successful operetta *La Belle Hélène* (1865). Other successes followed, including *La Vie Parisienne* (1866), *La Grande Duchesse de Gérolstein* (1867) and *La Périchole* (1868). From 1872 to 1876 he directed the Théâtre de la Gaîté, and in 1874 he produced there a revised version of *Orphée aux enfers*, described then as an "opéra-féerique." This venture was a financial failure and in 1876 he made a tour of the U.S. The remaining years of his life were devoted to composition. He died in Paris on Oct. 5, 1880.

His only grand opera, *Les Contes d'Hoffmann*, remained unfinished at his death. It was orchestrated and provided with recitatives by Ernest Guiraud, who also introduced the famous barcarolle taken from *Die Rheinnixen*. Described as an "opéra-fantastique," it was first produced at the Opéra-Comique on Feb. 10, 1881.

Writing in a fluent, elegant style and with a highly developed sense of both characterization and satire (particularly in his irreverent treatment of mythological subjects), Offenbach was appropriately named by Rossini "our little Mozart of the Champs Élysées." Indeed, he was almost as prolific as Mozart. He wrote over 100 stage works, many of which, transcending topical associations, were maintained in the repertory in the 20th century.

See S. Kracauer, *Offenbach and the Paris of His Time* (1937); S. Sitwell, *La Vie parisienne* (1937). (E. LR.)

OFFENBACH, a town of Germany in the *Land* (state) of Hesse which after partition of the nation following World War II became part of the Federal Republic of Germany. Pop. (1961) 116,195. Situated on the left bank of the Main near the Rhine–Main airport, with a river port (coal, oil), Offenbach lies 5 km. (3 mi.) upstream of Frankfurt. It adjoins the Cologne–Frankfurt–Nürnberg motorway and the Frankfurt–Beera–Berlin railway. In the town the alkaline Kaiser–Friedrich–Spring feeds a well 787 ft. deep.

The earliest mention of Offenbach was in a document of 977. It was part of the imperial forest of Dreieich and in 1407 a mint was established there. In 1486 it was acquired by Count (later Prince) von Isenburg-Birstein; the Isenburg castle has an impressive Renaissance façade. The town's prosperity began with an influx of Huguenot craftsmen in 1698–1703; it was annexed to Hesse in 1816. Offenbach was badly damaged in World War II and has since been rebuilt. New buildings include the town hall and offices of the federal board for distilled liquors, the directorate of the German meteorological service, the federal customs board and the chamber of trade and industry. The Klingspor museum has exhibits of modern calligraphy and book-printing.

The largest industrial town of old Hesse, Offenbach has a noted tanning and leather goods industry, with a unique leather museum and biannual leather trade exhibitions. Other industries include steelwork construction, machinery and electrical products, chemicals (dyes, soap, perfumes), soft drinks and textiles.

OFFENBURG, a town of Germany, in the *Land* (state) of Baden-Württemberg, which after partition of the nation following World War II became part of the Federal Republic of Germany. Pop. (1961) 27,569. It lies in the valley of the Kinzig river 63 km. (39 mi.) N. of Freiburg im Breisgau by road. Gothic and baroque buildings, picturesque lanes, fountains and half-timbered houses characterize the town, which is a rail junction and intersection point of important roads. Offenburg, the principal town of the Ortenau wine and fruit-growing district, is also an economic and cultural centre of middle Baden. Industries include printing, the production of structural steel, machinery, electrical equipment, chemicals, textiles and peppermint. The tourist trade is important. The town was founded by the Zähringer margraves in 1263 on the site of a Roman settlement; from 1289 to 1802 it was a free imperial city, and in 1846–49 a centre of the freedom movement in Baden. (RR. H.)

OFFICE MACHINES AND APPLIANCES. For a variety of reasons the work load of business offices has increased in striking fashion during the 20th century and, because much of the work is repetitive and routine, many different types of office machines and appliances have been developed to handle it. The manufacture of office machines and appliances has become a major industry, with new products constantly under development.

The decision to shift from manual to machine operation is usually determined by consideration of the following factors:

1. Saving of labour. This is basically a matter of determining estimated savings in direct labour charges during the life of the machine and comparing these savings with estimated machine costs.
2. Saving of time. Time saved in office routine may greatly improve operations elsewhere in the enterprise.
3. Effects upon personnel. Mechanization involves important changes in the nature of the work and may require retraining of workers. It may also cause morale problems. Such difficulties may nullify anticipated savings in labour.
4. Need for accuracy. Because errors in the office operations may result in annoyance to customers and possible loss of revenue, some firms find it desirable to purchase equipment that assures greater accuracy.

WRITING AND REPRODUCING MACHINES

Typewriters.—The typewriter, the most common of office machines, has been in use for approximately a century and has virtually eliminated handwritten letters and reports. Many improvements have, of course, been made in the typewriter since its invention, including the introduction of electric typewriters and automatic typewriters. (For a discussion of the history and development of the typewriter *see* the separate entry TYPEWRITER.)

Dictating and Transcribing Machines.—Dictating and transcribing machines provide for storage and later reproduction of spoken messages. Dictating machines are of two main types—mechanical or magnetic—and record the voice on plastic disks or belts, wire or coated tape. These materials can be removed from the machine after dictation and forwarded to the point of transcription. The transcribing machine, in a manner similar to the dictating machine, reproduces the dictated message so that the stenographer may type it. By use of these machines, stenographic transcription tasks can be carried out while the executive is dictating additional material. In this way, typing efficiency is much increased. A recent development has been the use of centralized dictating systems whereby individual microphones are connected to a central bank of dictating machines. The benefits of this method are the use of fewer machines and better flow of work.

Duplicating Machines.—Many different kinds of duplicating machines have been developed. Regardless of variation in process, all of these machines entail the preparation of a master copy from which duplicate copies are made by the machine. Note should be made of the fact that the use of carbon paper inserts makes the typewriter into a duplicating machine. This process is used extensively when a small number of copies is desired; it has a practical limit of about 8 copies on the manual and about 18 copies on the electric typewriter.

The stencil method of duplicating employs a coated fibre sheet (the stencil). Using a typewriter without a ribbon, the operator types the copy on the stencil, thus cutting the coating and exposing the fibre base to permit ink to pass through. Signatures or drawings may be placed on the stencil with a hand stylus. The stencil is then fastened to the outer surface of a hollow rotating cylinder that has a padded exterior surface saturated with ink. The ink flows through the cuts in the stencil as the cylinder rotates. Simultaneously, sheets of paper are passed under the cylinder and applied to the stencil under light pressure. Up to 5,000 copies can be made in this fashion from a single stencil, and stencils can be stored for considerable periods of time and then reused.

There are available two types of hectograph duplicators: gelatin and spirit. The gelatin process, now rarely used, requires the preparation of a special master paper upon which the copy to be duplicated is typed, written or drawn by use of a special ink or ribbon. This sheet is then pressed, face down, against a prepared moist gelatin surface and the image is transferred to the gelatin in reverse form. Sheets of paper pressed against this impregnated gelatin receive an image impression. Either a flatbed or rotary machine, similar to that used in the stencil method, may be used for making the duplicate copies. The master copy can be prepared in a variety of colours by using ink and carbon sheets of different shades. Multicoloured copies may thus be produced in one operation. The practical limit on copies produced by the gelatin process is from 50 to 100.

The spirit method is also referred to as the "direct" or "fluid" process. The master copy is prepared in the same way as for the gelatin process. The master sheet is then fastened to a rotating drum. As copy sheets, slightly moistened by a special liquid, are brought into direct contact with the master sheet, a minute amount of the carbon is transferred to them, resulting in the finished copies. Multicolour duplication in one operation is possible, as in the case of the gelatin process. The master sheets may be saved and reused. A further advantage of this process is that information can be added to or deleted from the master. Up to 300 copies can be made from one master sheet.

Offset duplicating processes require chemical fixing of copy on a metal sheet or, in more recent developments, preparation of a paperlike master copy by typewriter or by xerography. This master impression is inked and brought against an intermediate composition agent, usually rubber, to which the image is transferred. The image is immediately transferred to a copy sheet. This operation is performed by a power-driven machine. Many thousands of copies can be produced and masters can be stored for indefinite periods, and reused.

Raised-image duplicating processes use a variety of techniques for producing a master form on which the text stands in relief. The master forms are made by typesetting machines that closely resemble those used in printing.

Photocopying Machines.—Several different photographic processes have been devised for producing copies of drawings or written material. The most commonly used processes in this category are diffusion transfer and dye line. In the first process the master copy is made by typing, drawing or printing on a translucent paper or cloth sheet and is then placed upon sensitized negative paper and exposed to light. The negative is then placed in contact with a sheet of positive transfer paper and fed into a developer. When these two sheets are peeled apart the image is transferred to the positive paper. Dye line requires a translucent original and uses only one sheet of sensitized paper but the principle is similar. It is the cheapest of all photocopying processes. The dry dye line process uses ammonia fumes rather than liquid to develop the image and thus obviates problems of paper shrinkage. In both diffusion transfer and dye line, machines have been developed that perform all operations automatically.

Commercial application of heat or infrared copying methods, sometimes called thermography, are relatively new. Special copy paper and the original copy are placed in contact with each other and run through a machine where they are exposed to infrared or heat rays. The original copy absorbs the rays in areas darkened by print, line drawings or illustrations, thereby making the same

impressions on the heat-sensitive surface of the copy paper. The original with new copy paper attached may be put through the machine repeatedly to produce the number of copies desired.

Xerography as a means of copying is based on the principle of magnetism and thus differs from other methods that use chemicals or heat rays. It is generally regarded as a very flexible method, for it will copy anything that is written, printed, typed or drawn. It will also reproduce halftones and will enlarge, reduce or produce copy of the same size. This method of copying requires the preparation of a xerographic metal plate covered with powder and charged with electricity. Negatively charged powder adheres to the positively charged image to be copied. A sheet of ordinary paper is placed over the plate and charged positively. The copy paper attracts powder from the plate, forming a direct positive image. This paper is then heated for a few seconds to form a permanent print. The reproducing units in the process include a fuser, a copier and a special camera. These separate units have been combined in one machine and the whole process has been made fully automatic.

In contrast with the contact processes are the photographic processes wherein cameras are used to take pictures of the material to be reproduced. Most processes produce a negative from which positive copies in various sizes may be made.

Another modern development is the microfilm camera that produces negative images on film. This process is invaluable in saving space when storing documents of all sorts, for hundreds of pages of correspondence can be recorded on a small roll of microfilm. The film may be studied through a viewer, which shows it in its original size, or may be used to make reproductions of the original copy.

A host of specialized reproducing machines exists. The most widely used are check-writing machines that print amounts on checks so that they cannot be altered, and check-signing machines. Numbering, dating and receipting machines are small manually operated devices, the names of which are largely self-descriptive.

Imprinting Machines.—The most common of the machines in this category is the addressing machine, which addresses postcards, envelopes, shipping labels or tags. They are also used widely for imprinting checks, production orders, schedules, requisitions, time tickets, routing slips, tax bills and a host of other similar forms. There are three basic methods of reproduction on these machines: (1) spirit hectograph master cards, (2) stencil cards and (3) metal plates.

Hectograph master cards are made with the aid of hectograph carbon. The imprint on the card is transferred by means of a chemical solution to envelopes or other forms. Up to 250 imprints may be made from a single master card.

Stencil cards consists of small pieces of stencil tissue mounted in a cardboard frame. The copy to be imprinted is typed or written on the stencil tissue. When a drawer of cards is attached to the addressing machine, the machine automatically brings the cards and envelopes or other forms together, performs the imprinting, places the stencil cards in a tray and stacks the imprinted forms.

Metal plates of various sizes may be embossed with the desired copy on a special machine. The imprint is made on envelopes or other forms through an inked ribbon as the plates are fed through a machine. The machines operate automatically at high speed, and the plates are practically indestructible.

Many attachments for these machines are available to provide special services. For example, a selector permits certain plates to pass through the machine without imprinting, thus permitting mailings to go only to selected groups. A cut-off device permits the printing of selected data only. A repeating device prints the data several times before the plate is ejected, thus permitting names and addresses to be entered on envelopes and invoices, for example, in one operation. A dating device that enters the date on forms along with the other data embossed on the plates is used frequently in entering names and addresses on letters and statements. It is also possible to use these machines for distribution and addition of figure information. Holes punched in plates at predetermined points activate a sensing mechanism that translates desired information and lists it on forms being prepared. The preparation of billing records and payrolls are examples of ways in which this device may be used.

COMPUTING AND ACCOUNTING MACHINES

Calculating Machines.—Since the earliest days, man has aspired to free himself from the drudgery of calculation. Probably the earliest, and yet the most long-lasting, machine of this sort is the abacus (*q.v.*). Various versions of this instrument were extensively used in pre-Christian Rome and Greece as well as in Egypt and China, and continue to be widely used in much of the orient today. It was not, however, until the great rise of interest in natural philosophy in western Europe in the 17th century that serious interest arose in the development of calculating instruments. With the predictive abilities of the new physical theories of Galileo, Kepler, Descartes, Newton and others, there came a real desire to use these theories; and this desire called for substantial calculating.

John Napier invented the logarithm, which made the task of multiplying very much easier. The mechanizing of his logarithms led to the development of a whole class of calculating machines called analog or measurement devices.

In 1642 Blaise Pascal invented an adding machine that in some sense represents the first digital calculator. It is called digital since it performs its operations by a counting of integers. In 1671 Gottfried Wilhelm Leibniz invented a machine that performed the multiplication process by repeatedly adding. His "stepped-wheel," which still appears in a few 20th-century devices, was his most important contribution to the development of calculating machines.

During the last quarter of the 19th century, F. S. Baldwin, W. T. Odhner and A. Burkhardt developed machines that were more compact and made possible the modern desk calculators. They could perform the processes of addition, subtraction, multiplication and division, as well as the operations of multiplying or dividing by powers of 10 by shifting numbers left or right. They could store the result of an operation on counter wheels visible to the operator and data could be introduced by means of keys on a board. In all these machines, however, it is necessary for the operator to intervene at each step of a calculation, and the time required for the calculation thus depends upon the speed of the user.

Modern computing machines fall into three basic types: adding-listing, key-driven and rotary. Adding-listing machines are used for addition and subtraction; they list the numbers entered into the machine and the answer on a paper tape. Key-driven machines operate the mechanisms directly upon pressing the keys. Rotary machines need the additional operation of a lever or motor bar to record the number in the register. Some varieties of computing machines list the numbers entered into the machine and the answer on a paper tape; others show the numbers in the register of the machine where they are read from dials rather than from a printed tape. Computing machines are equipped with either full or ten-key keyboards (twelve for sterling countries). Full keyboard machines provide a column of ten keys for each digit position. Ten-key machines have only ten keys and the digit position is shifted to the left successively with each depression of the key.

In carrying out a mathematical calculation, man performs three distinct functions that must be incorporated into any calculating machine: (1) he must first of all perform certain basic arithmetic operations; (2) he must read from instruction sheets what he is to do next; *e.g.*, take the number in column 1 of his work sheet, multiply it by the quantity he has just produced and store the result in column 2; and (3) he must store his initial, intermediate and final results as well as his instructions on sheets of paper or other media.

Many attempts were made by Charles Babbage, Lord Kelvin and others to make the entire process automatic but technical difficulties stopped them short of reaching their goal. Vannevar Bush and his associates at the Massachusetts Institute of Technology developed and placed in operation the first differential analyzer in 1930. It was the first fully automatic calculating in-

strument that could be programmed to do different types of problems. It has a fourth organ, not required by the human operator, an input-output. This was a device that permitted communication between the mechanism and the human user. Since 1930 the developments in this field have been little short of fantastic. Electronic-mechanical calculators have been developed that are capable of performing extremely complex computations at high speeds. (*See* COMPUTER.)

Cash Registers.—Cash registers are recording and adding machines used to help a merchant control his business and to assist salespeople in serving customers. They make records of each transaction, both for the customer and the merchant, and protect against mistakes and dishonesty. They are made in many different types, some extremely simple and others highly complex. Most cash registers have certain fundamental features and functions. The typical machine indicates the amount of a transaction at the top of the register so that it can be seen by both customer and salesman. It keeps separate totals of sales by various classifications. It prints and issues a receipt on cash sales or overprints a record of the transaction on a sales docket on charge sales. It keeps within the register an audit strip, which is a complete printed record of every transaction that has been made. It also has special counters to show the number of customers handled and the number of each kind of transaction.

Accounting Machines.—Accounting machines, or bookkeeping machines, are complex devices combining features of the computing machines already described with some provision for writing. They have taken over much of the labour of bookkeeping. Billing machines, for example, are designed to typewrite names, addresses and descriptions, to multiply and extend, to figure discounts, and to add net total. A simple accounting machine generally has only one or two registers and no typewriter facility. Abbreviated description keys are used to denote the type of transaction and the carriage is designed to hold a number of forms at once. This enables the operator to post associated documents, such as ledger card and day book, simultaneously. The more elaborate accounting machines have many registers, often have a typewriter built in and carry out a number of operations automatically. Accounting machines post to one account at a time and frequently accumulate in the manner of cash registers to permit summarizing and distributing accounts. The window-posting accounting machine is in common use in banks, hotels and retail stores. Customers' statements or passbooks are inserted into the machine, which prints the transaction on these forms as well as on an audit sheet and automatically calculates new balances.

Classifying and Tabulating Machines.—These machines use cards upon which coded data are recorded; their function is to facilitate sorting and tabulation of diverse data. The simplest card systems function by notching the perforated perimeter of the card according to some code. These systems are limited to performance of sorting tasks. They are operated by a simple machine or device, frequently merely a metal rod, which is inserted in a specific perimeter location of a stack of cards. It will thus penetrate both notched and unnotched holes. When the rod is lifted, those cards with notched holes will fall out.

The first modern device of this class was designed for the automatic tallying or tabulation of statistics; but with extensive development modern tabulating machines are capable of automatically figuring and printing a report based on the information given to it in the form of perforations in cards or tape. Between 1834–54, Charles Babbage in England designed and partly built an "analytic engine" in which both the amount to be operated upon and the nature of the operation were entered by perforated cards. His machine was never completed, largely because modern precision techniques of fabricating metal parts to close tolerances were then unknown. Development of the modern tabulating machine was accomplished by H. Hollerith.

Hollerith's first contribution was a means of tallying census returns through electrical reading of the data punched on cards and accumulating the totals in separate registers. The system was successfully used in the U.S. census of 1890 and the British census of 1911. During the next decade notable improvements were made, including automatic feeding of the cards under brushes for reading and a machine for sorting the cards rapidly into desired groupings. The U.S. census in 1900 furnished particularly outstanding evidence of the possibilities of the system. The population volume was ready one year and seven months from the start of enumeration; it was estimated that hand tabulation of the three factors alone of sex, nativity and occupation would have required the services of 100 clerks for seven years and 11 months. Since 1901, its commercial utility has been greatly increased. Hollerith's ideas were taken up and improved by the International Business Machines corporation; those of his assistant, James Powers, were developed by the Remington Rand company. The tabulating method is now to be found in general use throughout the world.

Whenever a transaction involves a number of amounts that are later to be used as units two or more times in compiling various totals, it has been found to be generally economical to "translate" it on a perforated card. If, for instance, the data connected with the cost of production of a certain part are recorded on a card, this card can then be used in computing totals of individual wages, departmental costs, machine costs and productive hours.

The card upon which the data are recorded in the form of perforations has a column for each number or symbol to be entered. The digits 0 to 9 are denoted by holes punched proportionate distances from the bottom edge of the card starting with the 9 position. Above the 0 position is space for two additional perforations used principally for actuating certain control operations of the machine. These additional positions may also be used for special classification numbers, or, in combination with perforations in the regular digit position, to denote alphabetical characters. The card is divided vertically into fields each of which denotes a particular fact of the total information recorded. Some of the information is descriptive and some of it is quantitative. The former class controls sorting and indicating while the latter represents amounts to be totaled. Sorting and totaling are accomplished by different machines. Three separate mechanical devices are necessary to the system: a perforating machine or punch, a sorter and a tabulator. The ordinary form of perforating machine has a set of 12 punches under which the card is advanced a column at a time. By means of a skip bar or stops, certain fields can be skipped where no punching is to be done. There are also more complete types of perforating machines arranged to permit automatic duplication of information already on one card on to others, to "gang" punch any predetermined number of cards with identical data, to number cards consecutively as they are punched. The speed with which trained operators can perforate the cards depends on the nature of the information being recorded as well as its extent. An output of 350 punched cards per hour might be considered an average performance.

Sorting the cards into the desired groups for tabulation is done at the rate of from 400 to 2,000 cards per minute for each digit of the class number. One well-known form of sorting machine has 13 pockets, one for each possible columnar perforation and one for rejects. The tabulator, or accounting machine, which totals and prints the amounts perforated in given fields, is capable of several different applications. The simplest form of this device consists of a set of counters actuated through a reading mechanism. Two methods of reading the cards are in use: electrical and mechanical. In the former, brushes make electrical contact through the perforations, thereby actuating magnets to trip the counters. The mechanical method employs a full set of pins which are brought down upon the card momentarily at rest and which penetrate the perforations to actuate the counters mechanically. Printing tabulators are arranged either to total the cards at high speed—about 150 per minute—and then print the total, or to list each card individually followed by a total for the group. By means of special control features, the machines automatically take totals of several fields after each sorted group and also store the amounts for grand totals. A great deal of flexibility is attainable in the way the items and totals may be made to appear on the printed sheet. With alphabetical printing, addition or subtraction automatically sensed by the machine and devices

added to the printing section for handling report and bill forms, tabulating machines have become automatic accounting and billing machines.

MISCELLANEOUS OFFICE MACHINES

In offices where large quantities of coins must be handled, machines are used to sort, count, wrap or dispense coins. Sorting is accomplished by the simple process of sifting the coins of various sizes. Trip counters count the coins and wrapping machines wrap a standard number of coins in a paper wrapper. The coin-dispensing machine releases a specific sum in coin upon depression of the appropriate key on a keyboard similar to that of an adding machine.

Mail-handling machines are designed to expedite handling of large quantities of incoming and outgoing mail. As the bulk of the work is required to handle outgoing mail, most machines are designed to aid in this task. The main types are folding machines, inserting machines and envelope sealers. Stamp-affixing machines mechanically separate stamps from a roll, moisten them and apply them to envelopes. Postage meters print stamp charges directly on envelopes or on adhesive strips. The machines are set by postal employees to print postage equal to the amount of deposit paid. An automatic postage meter and mail scale machine feeds, stamps, seals and stacks letters at a high rate of speed. It also automatically weighs and computes the postage on parcel post packages.

The modern office is frequently of such size that efficient communication becomes a factor in maintaining the flow of work. Two-way voice systems operate on the telephone principle to permit communication between specific areas. In a commonly used version the individual may call any one or any combination of a limited number of stations by depressing appropriate keys on the receiver-transmitter box. When he speaks into the box his voice, amplified electrically, is broadcast from similar boxes at the various stations. Others may then reply in similar fashion from their stations.

Telewriting and teletype systems provide written or typed communications between two or more points. Messages are received and recorded even though no person is in attendance at the receiving machine. These systems are especially valuable for rapid intercommunication among a number of widely separated offices. Teletype systems, for example, frequently span an entire country.

Closed-circuit television installations permit viewers to see documents and hear explanations transmitted from distant locations. Rapid transmission of recorded information is thus possible for verification, identification or computation. Signatures or account balances may be transmitted for verification from a central office to many points instantaneously, thereby eliminating the need for maintenance of large numbers of duplicate records.

Paper cutters, punches, binding equipment and folding equipment are available in a wide range of sizes for office use. Document-destroying equipment disposes of outdated paper documents by shredding or chopping. Collating equipment assembles pages of printed matter in a specific order.

Time-recording machines combine a clock mechanism with a recording device to provide a quick, correct recording of the time of occurrence of certain routine events. Time-stamping machines are manually actuated to stamp the time upon letters and documents that are inserted in the machine. Time-recording clocks record the times of arrival and departure of employees. The employee inserts a time card into the machine when he arrives and again when he departs. Job-recording clocks function in identical fashion to record time of beginning and finishing particular tasks.

(S. J. Wa.)

OFFICE MANAGEMENT. Office workers play a vital part in the over-all operation of most enterprises. They provide services of many kinds related to the preparation and transmission of information, to data processing, and to the preparation, distribution and preservation of records. They prepare and distribute statistical and analytical reports of many kinds to assist responsible officials in evaluating and directing production and selling methods, personnel practices, expansion policies and similar activities.

The importance of rapid, accurate transmission of information, both internally and externally, as well as the importance of accurate, up-to-the-minute, detailed records, to the conduct of modern business affairs can hardly be over-emphasized. Some idea of the growing importance of office workers and of office management may be gained from a study of employment data. From 1870 to 1940, the total working force in the United States increased less than four times. During the same period, the number of clerical workers increased 15 times. For the short period from 1940 to 1955, the growth in the number of clerical workers continued at a high rate. During these years the total population increased by 24%; the total working force by 38%; the number of those engaged in clerical work by 80%. With this rapid growth in the number of clerical workers, there has come a growing concern for improved office management methods. For large firms the management of office activities can no longer be ignored as it was when office costs were small, business units limited in size and external contacts restricted. The same kind of careful planning and organizing of work found in factory production should be applied also to office work, particularly when the office is large.

FUNCTIONS OF OFFICE MANAGEMENT

The functions of office management parallel those of the management of any other area of an enterprise. Broadly stated, these functions consist of planning, organizing, initiating and controlling the work to be done. They distinguish a management from a non-management activity.

The planning function of office management is primarily concerned with defining the job that needs to be done. Because the office facilitates the work of other departments or areas, those responsible for office management must decide what facilitating services to provide. Those commonly provided are handling correspondence, maintaining financial records, preparing and transmitting messages, filing, duplicating reports, calculating, checking records and performing reception duties.

The organizing function of management is primarily concerned with a definition of the relationships that exist among the various units or departments of an enterprise, as well as among the various activities that are carried on within any one of the units. For office management, this function is frequently difficult to visualize or comprehend. Activities concerned with the transmission of information and data processing are closely related to production, distribution and research. They are rarely performed exclusively by clerical workers, and they are rarely placed under the exclusive control of the office manager. As a result, the responsibility for managing office activities is shared by a number of officials, operating on the same or at different levels of the organizational structure. Nevertheless, the organization function requires that these responsibilities and interrelationships be spelled out carefully and clearly. Those responsible for office management must apportion the work that is to be done, set up lines of authority and responsibility, and integrate clerical assistants into an effective working unit.

As office activities have grown in scope and importance, they have been placed more and more under the direction of professionally trained experts in office management. There is a growing tendency to centralize and group the office activities in an enterprise under one of these experts. There is also a growing tendency to elevate the position of this expert, usually the office manager, in the total organizational structure.

The initiating function of office management is concerned with getting the job started and completed according to the plans established and the organizational pattern adopted. Management officials must assume leadership in moving ahead, in motivating others to move with them and in inspiring them to use the highest capacities they possess.

The controlling function of office management is concerned with having clerical work done satisfactorily at reasonable cost. This function includes setting standards, improving methods, measuring work and determining unit costs. When office activities are scattered throughout an enterprise, as they frequently are, this function of office management is one of utmost importance.

These four functions of office management are closely related and interdependent. For convenience, they have been explained as separate steps, but in practice no sharp lines separate them.

OFFICE MANAGEMENT ACTIVITIES

Working Space.—As a rule, the office should be located where it can best provide services to the operating departments of an enterprise. Many other factors must, of course, be considered in providing space for clerical workers: size of the force, expansion needs, need for privacy, space costs, proximity to clerical supplies, adaptability to work flow, noise control, ventilation and provision of proper light. Working conditions affect the morale of clerical workers, as well as the efficiency with which they can accomplish their tasks. For these reasons, this responsibility of office management requires constant and careful attention.

Office space must provide room for private offices, general office areas, reception or service areas, and storage areas. These areas should be organized to permit free flow of work, adequate space for each worker and ease of supervision. Floor plans and work loads must be studied carefully in order to make efficient use of space, achieve uninterrupted processing of data and provide suitable working conditions.

Furniture and Equipment.—Office equipment is purchased to save labour and time, to insure accuracy of the finished product and to relieve clerical workers of the drudgery of performing routine tasks that can be handled by machines. As the need for data has increased, the types of equipment available for office work has multiplied. Office managers must keep themselves informed on the latest developments and improvements in equipment. Studies of operations must be made to determine where additional equipment might be used. The advantages and disadvantages of using machines for particular operations must be weighed carefully.

Office Personnel.—The management of clerical workers includes selecting, training, supervising, motivating and evaluating activities. In addition, it includes the planning of personnel requirements, interviewing applicants, handling employee grievances, making job evaluations, writing job descriptions, establishing salary scales and performing a host of related duties. The office manager may have sole responsibility for these matters, or they may come under the jurisdiction of the personnel manager.

Analyzing and Improving Working Methods.—Office management is concerned with the need for finding easier and better ways of billing, using the telephone, handling correspondence, filing, preparing duplicate copies of documents and performing other office duties. Careful studies have revealed the presence of much waste and needless duplication in the performance of these duties. Techniques of studying jobs and systems through the use of work distribution and flow process charts, man and machine charts, and motion analyses have been developed and used for some time in improving factory methods. The rewards are equally significant when these techniques are applied to office methods.

As the nerve centre of an enterprise, the office is mainly concerned with accumulating and classifying information and communicating it to interested parties. The information communicated must be complete and correct. At times, it must move with great speed. The office manager is responsible for developing and using letters and other information-handling media to meet these standards.

Handling and Storing Data.—Most enterprises depend upon office management to supply records of past and present performance needed in making decisions affecting operations. Much of the work that is done in the office is concerned with the preparation, classification and storage of statistical and narrative reports. There is need for both accuracy and speed in processing these reports. Office management must meet this challenge through proper planning and the application of adequate control methods.

Office Forms.—Office forms are sometimes referred to as the raw materials of the office, and office records as the end products. Forms are the media by which all manner of data are classified, recorded, distributed, duplicated, analyzed and stored. Poorly prepared forms result in duplication, waste and confusion. A well-planned program of forms control eliminates unnecessary forms, consolidates different forms doing the same thing, designs forms that may be handled efficiently and limits the distribution of forms to essential personnel.

Budgets and Reports.—Office management efficiency is frequently judged by the costs incurred in providing needed services. Cost, then, is one of the prime factors considered in making any decision regarding the employment of office personnel, purchase of office equipment or change of method. Among the methods used to control office costs are the following: preparation of budgets in which costs, savings and benefits are summarized and charted; preparation of reports in which accomplishments and needs are set forth; preparation of manuals in which procedures and policies are described; and the establishment of office standards. Office management is directly concerned with the preparation of these reports of its activities.

Improving Office Services.—Office management must provide leadership in achieving the goal of providing efficient service at low cost by increasing the productivity of office personnel. The office manager must take the lead in developing the kind of spirit among clerical workers that results in their working vigorously with management officials in reaching common aims. Techniques that have been found to be effective in accomplishing this objective are the following: (1) The office manager must believe in himself and the people who work with him; (2) he must set a good example; (3) he must seek and use the advice of the workers he is supervising; (4) he must keep them informed; (5) he must recognize their achievements and provide adequate rewards for services performed; (6) he must make employees feel that their work is important, and that each one is part of the office team; and (7) he must make each worker feel secure in his job.

SCIENTIFIC OFFICE MANAGEMENT

Frederick Winslow Taylor, known as the "father of scientific management," was probably the first person to apply scientific principles to office work. F. B. Copley's biography of Taylor includes a "Time Note" dated about 1885 that gives piece-work rates for 17 clerical operations, the implication being that Taylor had at least studied these operations, found the best method of performing them and controlled them to the extent that he offered an incentive wage for their accomplishment. Later he suggested to his assistants that they prepare instructions and set time standards for making entries on inventory cards. He is chiefly responsible for developing the idea of using standard paragraphs for handling routine correspondence. Another pioneer, Morris L. Cooke, applied scientific management principles in 1905 to the office of the American Society of Mechanical Engineers. In 1917 J. William Schulze of the Alexander Hamilton Institute published the first book on office management, *The American Office*. In 1917 W. H. Leffingwell's book on scientific office management was published, and his ideas led the thinking in this field for the next quarter of a century. Some of the leaders in the field of office management founded the National Association of Office Managers in 1919, and four years later incorporated the organization in Delaware under the name of the National Office Management Association. Its principal purposes were stated as follows: (1) To promote a free exchange of ideas on office organization and management among member concerns. (2) To encourage the work of standardization and to determine, insofar as possible, general standards of office work applicable to all industries. (3) To initiate and effect the application of scientific methods to the problems of office organization and management.

Scientific Method and Office Tasks.—The principles and ideas developed by Taylor, with modifications and additions contributed by later leaders in the "scientific" movement, have led to the establishment of a set of fundamental principles by which tasks are accomplished most efficiently. It has become axiomatic in management circles that those responsible for managing the work of the office must understand these principles and must know how to apply them. The principles may be stated as follows:

1. A simple and precise definition of the work to be done must be established, and the conditions under which the work is to be performed must be determined.

2. Each employee must be assigned specific work to do and must be vested with the authority to do it.

3. Each employee must be informed about his relationship to others engaged in the enterprise.

4. Each employee must know how he is to perform the tasks assigned to him.

5. Each employee must be encouraged to contribute his best efforts, through positive leadership, fair treatment and encouragement.

6. Satisfactory standards for measuring output must be developed and information on such standards must be placed in the hands of employees and managing officials.

7. Each employee's work must be evaluated in terms of the standards, and the employee must be informed of results and assisted in making any needed improvements.

Scientific Method and Office Problems.—Taylor also made many studies in an attempt to throw light on the problems confronting management. In conducting these studies he used scientific methods of investigation and as a result made important contributions to management knowledge. Some of his important findings were that high wages frequently resulted in low unit costs, that co-operation between employees and management officials was needed for highest productivity and that standards were necessary to control the products or services of an enterprise.

The steps in the scientific method are described in different terms in the various published works on office management, but all agree that the method involves solving problems by taking a series of well-defined and orderly steps. Each step in the method is important and must be taken in the proper sequence if the most satisfactory solutions to problems are to be found. The steps may be stated as follows:

1. The problem must be recognized and identified. It is understood that every problem is related to other problems but for purposes of intensive study it is necessary to isolate the particular problem to be treated.

2. Preliminary analyses and observations must be made. This step frequently includes a review of other investigations of the same or similar problems. It attempts to assess the importance of the problem under consideration and to weigh the possible advantages and benefits of its correct solution.

3. A hypothesis or tentative solution to the problem must be worked out on the basis of observation and experience; the tentative solution must then be proved or disproved on the basis of careful investigation.

4. The problem under study should be divided into its component parts so that each part may be studied carefully. The problem of purchasing a new piece of office equipment, for example, includes a study of original cost, maintenance, training of operators and adaptability to the work.

5. Adequate data must be collected and classified. On the basis of the data that have been collected, an answer to the over-all problem must be formulated and then tested in new or repeated applications.

6. The solution should be adjusted and restated. On the basis of the preceding step needed changes should be made in the answer. Great care should be taken to state and view the answer accurately in relation to the problem defined at the outset.

The alternative to the use of the scientific method of solving problems of office management is the use of tradition, experience or guesswork—all of which have been used in the past but none of which offers the promise of advances that may be made under the systematic approach. In summary, it can be stated that the scientific management method is based upon the belief that there is one best way of performing an operation or one best solution to a problem, and that systematic analysis is superior to guesswork in finding that one best way or solution.

OFFICERS, MILITARY, a term designating persons holding commissions and differentiating them, as leaders, from the enlisted or "other ranks" of a nation's armed services. The term usually refers to persons on active or full-time duty and indicates that there is a contractual arrangement between them and the state. These persons devote themselves to their country's defense as a principal and regular means of gaining a livelihood. Reserve officers and commissioned militiamen are also included as officers when on active duty, and in all nations they qualify in some measure under the term even when on an inactive status, since they give part-time service to the state under less binding contractual agreements. The term officer in the following context usually refers to the commissioned members of the regular, active armed forces, including women who hold commissions in the feminine, usually noncombatant components of the armed forces of most nations.

This article is organized according to the following outline:

I. HISTORICAL DEVELOPMENT

1. Ancient and Medieval.—Ancient armies were normally commanded by members of the nobility. In Egypt, for instance, military leaders ranked in society as the second of seven castes. In Assyria military men were the top social group in the nation. In neither of these cases could the noblemen who commanded the armies be considered officers in the modern sense that their livelihood was primarily military. Moreover, they were not bound to the state by a contract.

The citizen soldiers of both Greece and Rome were commanded by those among their number who exhibited qualities of leadership. However, these citizen soldiers eventually gave way to professional long-service regular soldiers. As a result, citizens in Greece and Rome who had a liking for military life chose it as a profession and remained in service as officers. Usually of the propertied classes or nobility, they commanded lower-class citizens of their nations, mercenaries and barbarians. Gaius Marius, about 106 B.C., opened the officer ranks to Roman citizens regardless of their social position. With the fall of Rome and the coming of the dark ages and feudalism the professional officer disappeared; not until the time of the French Revolution did military leaders come as close to the modern professional sense of the term as did officers of the Roman empire.

There was no general, long-service military class in feudal times. Each nobleman had his vassals for military duties in the short-lived campaigns of the dark ages and the early middle ages. The

main business of the knights was agriculture. The annual 40 days of military service owed by vassals to their lords prevented warfare from being more than a desultory occupation and in no way qualified the feudal nobles as professional officers.

Professionalism took its most significant step in the 15th century when free companies of Swiss, Italian and German soldiers sold their services wherever they were needed. These mercenaries were international freebooters, and their captains were competent leaders who, to some extent, qualified as officers in the modern sense. Their livelihood was warfare; they made a business of fighting, contracting with various princes or dukes for professional service. Their mercenary business passed out of existence about the middle of the 17th century with the disappearance of feudalism and the rise of dynastic standing armies.

2. 17th and 18th Centuries.—In the Thirty Years' War the modern grades or ranks of regimental officers developed in the well-organized Swedish army of Gustavus II Adolphus. He established the modern idea of the regiment with its colonel, and the battalion commanded by a lieutenant colonel, assisted by a major as the administrative chief and by an additional officer, a captain, who arranged for supplies. The companies were commanded by captains as a continuation of the free company method, while the subordinate officers in the unit were lieutenants.

It was during this period that the proprietary system replaced the obsolete combination of feudalism and free companies. Under this the colonel was the proprietor of his regiment, the captain the proprietor of his company. The king accepted them as his officers and armed them with authority to raise men. Initially under this system armies were raised for each campaign, and the regiments were made up from qualified volunteers. During the latter part of the 17th century, however, armies became permanent, or standing, and were kept up to strength by the regular influx of untrained recruits. The crown supplied the recruits and the money for maintaining the forces, the proprietorship of the colonels and captains being thus somewhat restricted.

The proprietary system gave to military office not only responsibilities but also certain profits. The officer was paid for the number of men that he mustered and was furnished other funds for their arms and food. Besides the profit resulting from economical —and sometimes parsimonious or fraudulent—discharge of his proprietary rights, the officer could sell his proprietary interest when he retired. Commissions, therefore, were valuable, and as late as 1871 could be purchased in the British army, even though the proprietary system had long since vanished. The purchase of the commission of a lieutenant colonel in a first-class regiment might cost as much as $30,000 (£6,200).

The general terminology for the grades of regimental officers having been established by Gustavus Adolphus, it remained largely for the French to develop the ranks above that of colonel.

Usually the king or prince was the "general" of a field army. The second in command was the lieutenant general, a nobleman who customarily commanded the aristocratic cavalry. A professional soldier—not necessarily a nobleman—usually commanded the infantry and was variously known as the sergeant major general or simply major general. It was his duty to form the army for battle and to take care of other administrative matters for the king or prince. (The title of sergeant major was carried through the regiments and battalions, where the sergeant major—sometimes called major or adjutant major—was the principal staff officer.) When, as was usually the case, the army was disbanded at the end of a campaign, the lieutenant general and major general had no command and thus lost their rank as well, reverting usually to their proprietary positions as colonels of permanent regiments.

Gradually, however, the title of marshal or field marshal was developing into a recognized, permanent rank in the French army. This resulted from the establishment of a permanent list of officers whose distinction and experience qualified them to serve as general, lieutenant general or major general in a field army. This marks one of the most important points in the evolution of the military officer—his permanent classification by rank and not by the actual temporary command he happened to hold. Following the establishment of the rank of marshal in the French army, there was the gradual, logical development of a list showing the precedence by rank of all officers in an army. The establishment of such general army lists naturally undermined the proprietary system of independent regiments, and this system passed out of existence for the most part in the late 18th century.

As armies grew larger in the 17th and 18th centuries, more general officers were needed. In time a lieutenant general, previously the designation for the second in command of an army, also became a permanent rank, immediately below that of marshal. The next lower grade was that of the sergeant major general, later shortened to major general. The lowest grade of general officer, that of brigadier, was created by Louis XIV.

3. French Revolution to Mid-20th Century.—During this period officer status was gradually opened to qualified soldiers in the ranks. Significantly, too, officer status was opened to a great number of technical positions unknown in warfare before the Industrial Revolution; for instance, officers supervising the production of guns and those responsible for signal communications.

In the British services prior to the 20th century, officers normally were paid so little that only the wealthy could afford commissions. Promotions from the ranks became common during World War I and soon after its termination measures were taken to extend the system to the regular army in peacetime. A limited number of young soldiers from the ranks (known as Y cadets) went each year to the royal military colleges for training as officers. In 1938 the British government made it a condition that all cadets for army commissions should serve for a short period in the ranks. The number of commissions granted from the ranks of the navy and air force was also increased. This reform in part did away with such disabilities as the low pay that required augmentation from a private income, and also eliminated the inactive status during which a regular officer had sometimes found himself on half pay. Consequently, the British officer class became more representative of the nation as a whole. Even the social barriers were broken down so that service as a British officer more closely paralleled that in the U.S. forces.

In Germany, even before the unification of the country in 1871 the influence of Prussia was pre-eminent in military affairs. This influence, which to a certain extent pervaded all Europe, continued right up to World War II. The Prussian landholding aristocracy, the Junkers, were the most powerful element of an essentially military society. Most officers came from the aristocracy of Prussia or the other German states, and by the end of the 19th century all were required to have a university degree or its equivalent. Approximately 40% came from cadet schools; the remainder had been reservists on active duty who had been recommended by their commanders as possessing the requisite military and social qualifications. The Junkers were able to assure that members of their group rose to high command and staff positions in the army. The arrogance of the Prussian officer was communicated to the rest of the German army and to the navy. There can be no question that this, as well as the Prussian emphasis on mechanical efficiency, detracted to some extent from the human qualities that have been found so essential to the making of good officers in democratic countries. Nevertheless, German thoroughness and attention to detail resulted in a high standard of efficiency throughout the entire army, and later in the German navy and air force. At the same time the German promotion system brought many brilliant and imaginative officers to positions of high command. In the development of the new German army of the Federal Republic of Germany after World War II, a conscious effort was made to eliminate the nondemocratic and mechanical characteristics of the old German officer corps, while retaining the traditionally high standards of efficiency. In this period the Germans looked to the United States for guidance in the organization of armed forces consistent with democratic principles.

The French nobility had largely been eliminated from influential military positions in the Napoleonic era. Men who might never have been more than sergeants in the armies of Louis XIV rose to be marshals under Napoleon. Against this background, the selection of officers in France during the 19th century was probably more democratic than that in any nation other than the U.S.

Nevertheless, aristocratic influences remained strong in the top command positions of the French army up to World War I. Throughout the 19th century and until the mid-20th century, French officers were well-schooled and able men, though officer positions declined in standing mainly because of the low pay.

In the far east the Japanese services were largely commanded by the nobility. Descendants of the traditional samurai class generally attained highest rank in both command and staff positions in the Japanese army and navy. A certain similarity developed between Germany and Japan in the rise of an essentially military society. Japanese officers displayed much of the arrogance found in the German armed forces of the 19th and early 20th centuries. The parallel continued after the defeat of both in World War II. Like the West Germans, the Japanese, with U.S. assistance, endeavoured to eliminate the autocratic abuses that had existed in their prewar forces, while retaining traditional military efficiency. East Germany, on the other hand, patterned its armed forces on the older German model, modified by contact with Soviet organization.

Russia, under the tsars, gave officer status almost entirely to the nobility. Before World War I the standards of the Russian officer corps were lax; there were a few capable officers but many were unbelievably careless and incompetent. This resulted in disastrous defeats in the Russo-Japanese War and in World War I. Following the Bolshevik Revolution, Lenin created an army from the proletariat, taking his leaders from among labourers and revolutionists.

During the period between World Wars I and II the Red army developed slowly but steadily, and many excellent officer schools were established. The growing efficiency and morale of the officer corps were seriously impaired, however, in the Stalinist purges of 1937. Glaring weaknesses were revealed in the Russo-Finnish War of 1939–40, but this experience enabled the Soviet leaders to make many last-minute improvements before Hitler attacked in 1941. At that time the top commanders were still the old Bolshevik leaders, but after the Red army suffered crushing defeats, these men were replaced by younger and better-trained officers. The vast area of the U.S.S.R. and the stubborn defensive qualities of the Soviet soldiers provided advantages that gave these new commanders a chance to gain experience in battle.

Soviet social and political experiments in the army were not wholly successful. After the Revolution officers and men were given common social status, but this soon proved unworkable. The trend was reversed until by mid-20th century there was a greater distinction between officers and men in the Soviet forces than in those of the western nations. The Soviet leadership was slower to acknowledge the failure of its system of political commissars. Until the early days of World War II there had been in each army unit commissars whose function was to indoctrinate the troops with Communist propaganda and to check on the political reliability of the officers. While there was a partial return to this system after World War II, these political officers no longer wielded their former power.

Officers in the U.S. services have always represented a cross section of the population and have been obtained by various systems of selection. In the early days of the republic, men ignorant of military affairs became officers through political influence. The evils of this practice were great; history mentions companies electing captains in the American Revolution on the condition that they share their pay with the other men. There were similar experiences in the War of 1812 and again to a lesser degree in the Civil War, when governors of states appointed officers in the volunteer forces, often without regard to their experience. Many of the small nucleus of regular officers who had been trained at the U.S. Military academy got their chance in the war by obtaining volunteer appointments from state governors at ranks far higher than the permanent ones they held. The experience of Gen. Philip Sheridan, who fought as a captain in the regular army for a full year before he was elevated to a colonelcy of volunteers, was common among the regulars.

After comparable experiences in the Spanish-American War, the United States made strong efforts in both World Wars I and II to select and promote officers on the basis of merit. In these wars, the higher command and staff positions were given most often to regular officers. But in World War II more than 98% of army officers and 96% of navy officers were nonregulars. Some had been reserve officers before the war, but most were essentially civilians, selected from the greatly expanded enlisted ranks and trained at officer candidate schools. A few specialists—lawyers, doctors, railroadmen, etc.—had duties almost identical with those of their civilian occupations.

During World War I the air officer, usually a pilot, played a significant role in the armed forces of all major belligerents. In Britain toward the end of World War I, and in Germany between World Wars I and II, a coequal service—the air force—was established, but air units remained elements of the armies and navies of most other major nations until after the close of World War II. In 1947 the U.S. air force became a separate entity, but in the U.S.S.R. the air force remained an integral part of the Soviet army.

II. THE OFFICER AS A LEADER

In the 20th century the forces of social evolution and revolution have tended to reduce, but not to eliminate, the traditional distinctions between officers and enlisted men in pay, social status and privileges. Nations today draw their officers from a cross section of their people and make it possible for enlisted men to become officers.

The distinction between officers and enlisted men, or "other ranks," is one primarily of professional status and responsibility. Many enlisted men of the regular services in most nations are highly skilled and trained technicians; senior noncommissioned officers are generally as dedicated to their military careers as any officer. Most enlisted men, however, lack the professional background, education and motivation that are considered to be the fundamental officer characteristics. Because of this essential difference, enlisted men under the military and civil law of most nations cannot assume the legal responsibilities of command that an officer cannot avoid.

Armed forces exist to support and to carry out national policy and particularly to defend their nations from hostile attack. It is the function of officers to provide leadership for these military establishments. This leadership is exercised in three major categories of activity: (1) the armed forces must be recruited, organized and equipped; (2) they must be trained; (3) they must be controlled and led in military operations. The objective of this exercise of leadership must be to assure success in battle, whether or not the individual officer and his men are ever actually engaged in combat.

Leadership is a concept defying precise analysis in its military as well as its nonmilitary manifestations. Through a study of history, however, it is possible to deduce certain qualities that all military leaders should possess. While the general nature of military leadership is comparable with that in any field of human endeavour, it is nonetheless distinguished by the highly specialized characteristics that the officer must possess.

1. Military Competence.—This is the first and most distinctive of military leadership qualities. It requires a profound knowledge of military theory as well as understanding and skill in applying this theory. Nothing is more difficult in the military profession. The officer may prepare for the day of battle for many years, but the exercise of his leadership in war usually occupies a relatively brief period. Obviously, then, there is an aspect of unreality in his preparation. Furthermore, what he has learned by study and artificial peacetime experience can easily become outdated before he is called upon to exercise leadership in combat. Only through alertness in responding to technological developments and by repeated training exercises can the officer hope to obtain and preserve this essential skill. His success is demonstrated by his ability to take positive action in the flexible application of technical knowledge and theoretical principles to a wide variety of specific situations.

The officer must know thoroughly the tools that will be available in war. While this naturally includes weapons and all manner of

complex equipment, the most important tools are the men he leads in battle. The officer must understand their general human and national qualities, and further must be aware of the characteristics and limitations of the specific individuals who will be under his command in battle. Knowledge of the military art, flexibility and all the other requirements of leadership avail nothing if the officer does not understand how to deal with the human beings over whom he holds a position of power. An understanding of his men does not mean that an officer must fatalistically accept their limitations. On the contrary, he should endeavour to minimize inherent weaknesses and to improve the quality of the human tools with which he must fight. This is done through training and the simultaneous achievement of high standards of discipline.

2. Training and Discipline.—In the armies of modern democratic countries discipline cannot be achieved through the so-called Prussian system of unthinking obedience from mechanical soldiers. Such a system is not compatible with democratic concepts or the requirements of modern warfare. The increasing destructiveness and efficiency of weapons has compelled increasing dispersion of land, naval and air forces in battle. In the isolation of individuals or small units there is an incessant demand for the exercise of initiative and the display of moral and physical courage that can be derived only from confidence fostered by an understanding system of discipline.

This confidence is not merely the result of thorough, painstaking training of men in the use of weapons and equipment; it stems equally from the officer's diligence in care of his men, resolute justice, creative intelligence and respect for the dignity of the individual. The object of the relationship between officers and their men is so to strengthen the will and abilities of the latter that they will be able to take voluntary action in the heat of battle. The officer-leader stands or falls on the results of those vital moments when the decision is in the hands of the men with whom he has trained and lived.

3. Character Traits.—The officer must be able to inspire in his men a desire to work together toward a common goal. This cannot be achieved either by routine performance of his duties or by trying to gain the friendship and liking of his subordinates. He must demonstrate his dedicated enthusiasm for national objectives and ideals and for the honour and glory of the organization he commands. This, combined with military competence and insistence upon high standards of discipline, will ensure the respect, confidence and loyalty of his men. Personal courage is an absolutely indispensable quality. Since the officer will have normal, human reactions to danger, he must exercise the strongest self-discipline in combat. This does not mean that he should recklessly expose himself to danger or pretend an absence of fear. He must, however, share the risks of his men, must never demand them to perform actions that he would not dare himself and must remain cool and self-possessed in combat. Finally the leader must be able to endure calamity without loss of equilibrium. He should be able to persevere in adversity and carry on with flexibility and determination to achieve assigned objectives, regardless of setbacks or even crushing defeat.

III. RANKS OR GRADES OF OFFICERS

A common pattern of officer ranks or grades has developed in the armed forces of the principal nations, despite differences in titles. The nature of the pattern, the commonest titles of ranks and grades and major differences between services and nations are shown in the table. It should be noted that officer grades in the U.S. air force are practically identical with those of the U.S. army, and that there is comparable similarity in the grades of the French army and air force.

1. Warrant Officers and Cadets.—Below the normal officer grades there are frequently two categories of ranks in which the individuals enjoy officer status but do not have full officer responsibility.

Warrant Officer.—Warrant officers' duties are generally administrative or technical in nature. It should be noted that in the British army the term warrant officer (like that of *adjudant* in the French army) applies to senior noncommissioned officers, who do not possess officer status comparable with that of U.S. warrant officers, for instance. In the Royal Navy the commissioned warrant officer enjoys full officer privileges without the full status.

Cadet.—This term generally applies to young men attending special training schools in preparation for regular careers in the armed forces. U.S. and British naval cadets are called midshipmen.

2. Company Grade Officers.—This is an army (and often air force, though not Royal Air Force) term applying to the lowest of three major groupings of commissioned officer grades. There is no comparable naval term, though members of the lower ranking group are sometimes referred to as "junior officers." The grades are as follows:

Second Lieutenant.—This officer is usually an assistant platoon commander in most armies. The equivalent Royal Air Force rank is pilot officer, while the U.S. navy equivalent is ensign.

Lieutenant.—In the U.S. army and air force this officer is a first lieutenant; in Belgium he is known as the platoon chief, which is indicative of his typical responsibility. He may also be second in command of a company. In the Royal Navy, which has no lower commissioned rank, he is a sublieutenant, while in the Royal Air Force he is a flying officer. The Soviet army has three grades of lieutenant rather than two as in most nations.

Captain.—In most armies this officer is a company commander, the title going back to the days of mercenary companies. In the British army he may sometimes be second in command of a company. This rank is equivalent to lieutenant in most navies and flight lieutenant in the Royal Air Force.

3. Field Grade Officers.—This is the U.S. army and air force term for the second major grouping of officers. In the navy and British services these grades are sometimes called senior officers. Royal Air Force rank titles in this group indicate the position normally filled by men of each grade: squadron leader, wing commander and group captain. Field officer grades are as follows:

Major.—In most armies this officer, lineal descendant of the historical sergeant major, is second in command of a battalion, though in the French army he may command a battalion, while in the British army junior majors often command companies. In navies the lieutenant commander usually commands small combat vessels, such as frigates or destroyer escorts.

Lieutenant Colonel.—In most countries this officer commands an infantry battalion, or is second in command of a regiment of more than one battalion. In the British army he also commands a cavalry, artillery, engineer, etc., regiment. The equivalent naval rank is commander, an officer who usually commands intermediate size vessels, such as destroyers, or who may be executive officer of a larger vessel.

Colonel.—In most armies this rank denotes command of a regiment or similar group. The equivalent naval rank is captain. In the British army it is often held by senior staff officers, but not by active regimental officers. The British regiment is an administrative unit and has a dignitary called the colonel of the regiment. He acts as the "father of the regiment" and is usually one of its distinguished serving or retired senior officers. Many British regiments also have a colonel in chief, who is always a member of the British, or a foreign, royal family. A few units—mostly in the territorial army—have, in addition, "honorary colonels," who are usually distinguished persons selected because of some past connection with the unit.

Brigadier.—This is a special rank found only in the British army and the armies of nations that have adopted British organization. This officer commands a brigade—the combat organization comparable to the regiment in most other armies. Some staff positions are also held by brigadiers. In the British army the brigadier is not a general officer, but is a colonel who is given special appointment with the temporary rank of brigadier while holding his specific command or staff position. The position of commodore in the Royal Navy is comparable in that it is not a separate rank, but is a special appointment of a captain.

4. General or Flag Officers.—This third and most exclusive grouping of officers includes those in senior command and staff positions. "General officer" is the army term and "flag officer" the naval term.

Corresponding Ranks in the U.S., British, French and Soviet Armed Forces

U.S. army*	U.S. navy	British army	British navy	British air force	French army	Soviet army
Warrant officer	Warrant officer		Warrant officer	Warrant officer		
Cadet	Midshipman	Cadet	Midshipman	Cadet	Cadet	Officer cadet
2nd lieutenant	Ensign	2nd lieutenant	Sublieutenant	Pilot officer	Underlieutenant	Junior lieutenant
1st lieutenant	Lieutenant (junior grade)	Lieutenant		Flying officer	Lieutenant	Lieutenant Senior lieutenant
Captain	Lieutenant	Captain	Lieutenant	Flight lieutenant	Captain	Captain
Major	Lieutenant commander	Major	Lieutenant commander	Squadron leader	Commandant	Major
Lieutenant colonel	Commander	Lieutenant colonel	Commander	Wing commander	Lieutenant colonel	Lieutenant colonel
Colonel	Captain	Colonel Brigadier	Captain Commodore	Group captain	Colonel	Colonel
Brigadier general	Rear admiral (lower half of list)			Air commodore	Brigadier general	Major general
Major general	Rear admiral (upper half of list)	Major general	Rear admiral	Air vice-marshal	Divisional general	Lieutenant general
Lieutenant general	Vice-admiral	Lieutenant general	Vice-admiral	Air marshal	Corps general	General
General	Admiral	General	Admiral	Air chief marshal	Army general	Colonel general
General of the army	Fleet admiral	Field marshal	Admiral of the fleet	Marshal of the Royal Air Force	Marshal of France	Marshal

*Ranks for officers of the U.S. air force are the same as for the U.S. army except that the highest rank is general of the air force.

Brigadier General.—Traditionally this was the title of the commander of a brigade. Brigadier generals, in armies without a brigade structure, are normally second in command of divisions, or in command of divisional or corps artillery establishments, or of specially organized task forces of several combined arms, or may hold senior staff positions. The Soviet major general is comparable to brigadier general in other armies. In the U.S. navy the rank of commodore is rarely used (though certain officers, because of the positions they hold, are given the title of commodore), and officers in the lower half of the list of rear admirals are considered to rank with brigadier generals. Air commodore is the equivalent Royal Air Force rank.

Major General.—The commander of a division is given this title in practically all armies of the world; many high general staff positions are also given this rank. In the U.S. navy, officers in the upper half of the list of rear admirals rank with army and air force major generals. In the Soviet army lieutenant generals are ordinarily the equivalent of major generals in other countries. The comparable Royal Air Force rank is air vice-marshal.

Lieutenant General.—In most armies this officer commands a corps of two or more divisions. The comparable Soviet rank is general. In most navies the equivalent rank is vice-admiral and in the Royal Air Force it is air marshal.

General.—This grade is normally identified with the commander of a field army. Senior generals may command army groups of two or more field armies, or command combat theatres of operations in wartime. The equivalent naval rank is admiral while that of the Royal Air Force is air chief marshal. In the Soviet army the comparable rank is colonel general.

Field Marshal.—In Britain this ancient rank is held by a few senior army officers. If not already a field marshal, the chief of the imperial general staff is usually made one soon after being appointed. In the Royal Navy the comparable rank is admiral of the fleet, and the air equivalent is marshal of the Royal Air Force. In the Soviet army this rank is generally held by officers commanding army groups or higher command. In France the title of *maréchal de France* (marshal of France) is purely honorary and is awarded by the French government only to especially distinguished, victorious generals.

After World War I the U.S. congress conferred the unique title of general of the armies of the United States on Gen. John J. Pershing. A comparable rank, admiral of the navy, had been given to Adm. George Dewey in 1899. The ranks of general of the army (unused since 1891) and fleet admiral were authorized by congress during World War II as the equivalent of field marshal and conferred on selected commanders: Generals George C. Marshall, Douglas MacArthur, Dwight D. Eisenhower and Henry H. Arnold (the title of whose rank was changed to general of the air force when that service was separated from the army in 1947); Admirals William D. Leahy, Ernest J. King and Chester W. Nimitz. Later Gen. Omar Bradley attained the rank of general of the army and Adm. William F. Halsey became a fleet admiral. Eisenhower, who resigned his rank to become president, was reinstated to it in 1961. (T. N. D.)

5. Brevet.—This term, a diminutive of the French *bref*, originally denoted a brief official note; more commonly it applies to a form of military commission used in the U.S. and British armies. Under the system wherein an officer was customarily promoted within his regiment or corps, a brevet conferred upon him a rank in the army-at-large higher than that held in his corps. Frequently it carried with it the pay, right to command and uniform of the higher grade. In the United States especially, brevet rank was widely bestowed as a reward for outstanding service; it became the subject of extensive confusion and controversy during the American Civil War. After 1865, U.S. brevet rank was gradually stripped of its benefits and officers were rewarded instead by decorations. (*See* MEDALS AND DECORATIONS.) Commission by brevet was declared obsolete in 1922. Special commissions bearing some of the characteristics of the brevet have been used in other armies. (F. P. T.)

IV. SOURCE OF OFFICER MATERIAL

In all major nations the primary sources of regular officers are special military, naval and air academies or colleges. These service academies, while differing among nations and services, have much in common. They are generally open to youths between 17 and 22 years of age, and all have strict physical and mental requirements for admission and require that candidates be unmarried. In addition, most nations offer opportunities to outstanding enlisted men and to graduates of universities and colleges to qualify for commissions as officers, either directly, or through the service academies or through intensive courses at officer candidate schools.

1. United States.—Regular officers in the United States services are obtained from three principal sources: from the three service academies; from civilian colleges and universities; and from among selected reserve officers. Some of the reserve officers obtain their commissions through Reserve Officer Training corps courses in civilian colleges, others through attending officer candidate schools as enlisted men.

Many regular army officers are graduates of the U.S. Military academy at West Point, N.Y. This academy, established in 1802, is one of the oldest service academies in the world. The naval equivalent is the U.S. Naval academy at Annapolis, Md., which was established in 1845. The U.S. Air Force academy was founded at Denver, Colo., in 1954, opened in 1955 and moved to permanent quarters near Colorado Springs, Colo., in 1958.

The student bodies for these academies are filled mainly by congressional appointment. The president also has a number of appointments that are often used for the sons of deceased veterans, and the regular services and the national guard have appointments open to enlisted men on a competitive basis.

All three academies offer a four-year college-type curriculum at government expense, leading to a bachelor of science degree. In addition there is intensive military instruction. The objective of the schools is to produce officers who have the qualities and character essential to their continuing development as leaders. The academies generally seek to implant a high sense of duty and patriotism, while assuring mental and physical fitness.

Upon successful completion of the four-year course the graduate is commissioned a second lieutenant in the army or air force, or an

ensign in the navy. In the 1960s West Point and Annapolis did not furnish even a majority of regular officers in the services, since far larger numbers were commissioned from civilian colleges or entered from the reserve officer group or the enlisted ranks. The Air Force academy, of course, was only beginning to supply officers for its service. Commissions in the air force and navy are also given to those who successfully pass through the flight instruction programs of these services. Although there are certain academic prerequisites (normally two years of college) time spent in the programs themselves varies with the individual's flying proficiency.

2. Great Britain.—Great Britain has obtained most of its regular officers from its military colleges. Medical, legal and some other technical officers, as in the U.S., have been obtained mostly from graduates of civilian universities. Prior to World War II, Britain had two cadet schools for its army: the Royal Military college at Sandhurst (1799) and the Royal Military academy at Woolwich (1741). Sandhurst was a school for officers of the infantry, tank corps and other line elements, while Woolwich trained artillery, engineer and signal officers.

Up to 1914 entry into these colleges was confined almost solely to the sons of upper-class parents. Between World Wars I and II, however, various changes were made and the colleges were put on a more democratic footing. By 1938 a short period in the ranks, as a prerequisite to officer candidacy, had become the rule rather than the exception. The changes of 1938 also made it possible for a youth who could meet the entrance requirements to obtain military training at government expense. Both Woolwich and Sandhurst differed considerably from the U.S. Military academy in that emphasis was upon military training, no effort being made to obtain a university degree for the cadets in the shorter, two-year course. Since the great majority of cadets had attended public schools or universities, however, by the time they received their commissions they had the equivalent of a college education. These schools furnished about three-fourths of the regular officer corps, the remainder coming from university graduates, directly from the army and from commonwealth nations.

In the post-World War II period, Sandhurst and Woolwich were consolidated into a single Royal Military academy located at Sandhurst. Because the reform of 1938 had broadened the source of applicants, there was some lowering of the standards of prior education of cadets from pre-World War II days. Consequently, there has been increased emphasis on academic subjects.

The Britannia Royal Naval college at Dartmouth (1729) and the Royal Air Force college, Cranwell (1920), the latter of which trains cadets for regular commissions as pilots and navigators, are the British naval and air counterparts of Sandhurst. Their courses are somewhat longer than at Sandhurst; otherwise they are comparable in scope and objectives. The Royal Air Force technical college at Henlow gives professional training for officers of the technical branch of the service.

3. France.—The principal source of officers for the French army is the École Spéciale Militaire, formerly located at St. Cyr, near Versailles, but moved to Brittany as the result of the destruction of its buildings in World War II. Like Sandhurst, St. Cyr (as it is still called) has a two-year course, except that selected noncommissioned officers may obtain a commission in one year of intensive study.

In past years most French artillery and engineer officers received their cadet training in a two-year course at the École Polytechnique in Paris. Polytechnique has become essentially a civilian engineering school, and by the 1960s only a few members of each class were electing to enter the military forces as a career. It is a government school, however, including military training, and a certain percentage of its graduates become reserve officers who must serve a period of active duty in the army.

The French navy obtains most of its officers from the École Navale, near Brest in Brittany, while the air force school is the École de l'Air, at Salon-de-Provence. Both schools feature three-year courses. The navy and air force, like the army, also obtain some of their technical officers from the École Polytechnique.

4. Soviet Union.—Before World War II the U.S.S.R. had no cadet colleges similar to those of the western nations. However, there were many branch officer candidate schools, including 15 for the infantry and a smaller number for the artillery. Qualified enlisted men are still allowed to compete for admission to these schools, receiving commissions after a course of three years. Some technicians, particularly engineers, are given direct commissions after university graduation.

During World War II the professionalization of the Soviet army was given impetus by the establishment of a number of Suvorov junior military academies. These schools accept boys—frequently from military families—at the age of nine or ten and subject them to seven years of training in military and secondary-school subjects, after which they are sent on to the three-year officer candidate schools. The Nakhimov schools for the navy are similar to the army's Suvorov schools.

See also MILITARY, NAVAL AND AIR ACADEMIES.

V. OFFICER TRAINING

All modern armies lay great stress on the continuous training of officers after they have received their commissions. This is particularly important because peacetime experience can never duplicate that of war and rapidly becomes outdated. Officers are schooled in the theories of tactics and strategy, in the principles of war and in the latest weapons systems and techniques whereby these theories and principles are applied in modern combat. Flexibility of mind is the goal in military education.

The army officer recently graduated from a military academy is usually given two or three years in command of a platoon of soldiers to acquaint him with the problems of leadership and to impress upon him the necessity for knowing small-unit tactics as they apply to the soldier in the ranks. Moreover, in such experience the young officer learns each soldier's job, so that he can show a rifleman or machine gunner how to handle his weapon. After a period of command, the officer may go to a school of his arm, such as infantry or artillery, to obtain a basic knowledge of its tactics and techniques. In some armies, this training of the early years is reversed on the theory that the junior officer is better qualified to command men if he has had the benefit of tactical schooling.

In general, the training of army officers runs to the following pattern in most nations: (1) basic military and academic education in military academy; (2) command at platoon level or its equivalent; (3) basic school of the arm; (4) command at the company level; (5) advanced school of the arm; (6) staff at battalion or regimental level; (7) staff college; (8) staff assignment in a higher headquarters; (9) command at the battalion level; (10) war college; and (11) the remainder of the career usually including both command and staff assignments. Into this pattern, from time to time, may come special assignments such as duty with reserve components or with a military mission in a foreign country. While the pattern of service for naval and air force officers naturally varies somewhat from that of army officers, these follow a similar scheme of rotation of duties, including school, command, staff and special assignments.

Much of the officer's training is concentrated on learning tactics and staff procedure by application so that these can be performed almost automatically. This is not to say that schooling is unthinking or adjusted to the mediocre. Rather it is based upon the requirements of service and the need for established, well-understood procedures, so that action will be prompt and efficient in the stress of combat, and to assure maximum co-ordination under any circumstances between officers who may never have had an opportunity to practise working together. Experience has proved that close adherence to a soundly formulated military doctrine is the surest guarantee of obtaining the best-trained men and of assuring uniformly high standards of training and achievement through the entire service.

1. United States.—Officer training in the U.S. services at mid-20th century followed very closely the pattern noted above. Only those officers showing the greatest potential for staff and command duties—approximately 50% of the officer corps—are selected for staff college. These are usually captains or majors in their early 30s. A smaller percentage—colonels, about 10 or 15 years older—are selected to attend the National War college, the In-

Industrial College of the Armed Forces or one of the three service war colleges. Many of these, as lieutenant colonels or commanders, have attended a joint staff college for special training in operations of the combined services.

During the first ten years of his career, an army officer who began his service in a line branch—infantry, artillery or armour—may receive specialist training in one of the technical branches, such as ordnance, signal communications or engineers. Some of these officers will transfer permanently to the service branches, with further training in civilian universities. From these, for the most part, are eventually selected the students who attend the Industrial college, where they study the economic aspects of war and industrial mobilization. There are also specialist opportunities for young navy and air force officers. Many of these young officers also complete their military schooling in the Industrial college.

2. **Great Britain.**—The British army officer at mid-century, like his U.S. counterpart, becomes a platoon commander shortly after he is commissioned. He is expected after two years of service to have a knowledge of the interior management, economy and discipline of a company. Subsequently he is required to pass professional examinations in order to qualify for promotion and in order to qualify for attendance at the higher military schools. The patterns for officers of the Royal Navy and Royal Air Force are similar.

After about eight years' service, specially selected officers attend one of the service staff colleges. On graduating, these officers can expect staff assignments, either in one of the service ministries in London or in major commands in Great Britain or overseas. There is a special staff college for joint service operations, and above that is the Imperial Defence college, equivalent to the U.S. National War college, for the study of higher strategy and military policy by officers of all services of all commonwealth countries.

3. **France.**—The French training system was the chief model for the U.S. and Great Britain. Great emphasis is placed upon qualification both in education and military training. After attending branch or specialist school, an army officer can expect to attend the École de Guerre some time between the ages of 28 and 38. This school, with its ten-month course, is designed to train officers for staff duties and the command of larger units. At about the age of 45, selected colonels attend the French war college—the École Supérieure de Guerre—for a two-year course in the higher art of war. The higher schooling of French navy and air force officers is similar.

4. **Soviet Union.**—Officers of the Soviet forces are trained at branch service schools, much as in the western democracies. Also the more capable officers are sent to staff schools and eventually the war college. A Soviet officer can count on spending almost twice as much time in schools as his western counterpart. The Soviet services place great emphasis on two items: political beliefs of the individual and ability to command troops.

VI. THE OFFICERS' SERVICE

While training requirements are similar for officers in the armed forces of all nations, there are great differences in the sort of places in which they serve and in the kind of duty they perform when not in school. The usual expectancy in most armies and air forces at mid-century was that officers would command troops or serve in combat units from one-fourth to one-half of their careers. A similar proportion of a naval officer's service would be at sea. This requirement, however, was constantly being lowered because of the growing complexity of war, which increased the demand for general staff officers and technical specialists.

The high command in most armies is normally given to the line officer, with a background in infantry, artillery or tanks, who has alternated his command experience with general staff duties. These officers will in time have taken very divergent paths from those of the technical experts, qualifying themselves in the later years of their service more as executives and administrators than as specialists in technical fields.

The duties of officers in the major countries require a certain amount of overseas service, either in military missions, strategic outposts or colonies. Accordingly, the officer alternately moves from an army post to an overseas garrison, or to a civilian community while on duty with militia or reserve units. The duties are varied and frequently stimulating because of new interests and new places.

1. **General Staff.**—An officer in this field is required to know the functions of personnel, intelligence, plans, operations, training or supply. The knowledge he brings with him of the men in the ranks assists him in determining whether his policy on paper can be carried out by men in units. Many general staff problems are concerned with political-military affairs and grand strategy. The training and background of the ordinary officer are not sufficient to equip him adequately in these matters. Consequently such jobs are assigned to officers who have demonstrated that they possess the necessary qualities of intellect, who have maintained a lively interest in world affairs and who have attained a sense of proportion in dealing with complex matters.

2. **Technical and Supply Services.**—Officers in these services may possibly be graduates of engineering schools as well as of a military academy. Their work in signal communications, ordnance or procurement of supplies brings them into frequent contact with business and industrial men. Mutual understanding by these groups is essential to the successful operation of industrial mobilization in the event of war.

3. **Methods of Promotion.**—In modern forces, officers are promoted through seniority in length of service, by selection on the basis of merit or, most frequently, by some combination of the two. For instance, most selection systems require a certain seniority before an officer can be pushed ahead of his contemporaries. In time of peace, when vacancies are few, the length of service requirements for selection may be increased. Promotion by seniority alone assures adequate reward for faithful service; it may, however, result in the promotion of less competent officers, at the same time failing to take full advantage of the potentialities of more capable, younger men.

In peacetime, promotion is normally a permanent advancement, while in wartime the tremendous expansion of the armed forces requires temporary promotions. Postwar contraction of the services often requires officers to drop back one or two grades from their advanced temporary rank. In World War II, for instance, in the U.S. services there were many cases of permanent captains who held the rank of brigadier and even major general, and many of these, despite proved ability, had to return to the grade of colonel after the war.

The armed forces of most nations use some sort of qualification report as an important basis for selecting officers for promotion. In the U.S. services these reports are submitted periodically, usually once or twice a year, and are prepared by the immediate commander or supervisor of the officer. After the next higher commander adds his comments, these reports are sent to the service headquarters in Washington, D.C., for evaluation and file. Reports are evaluated by electronic means, and each report is given a rating. The average of these ratings over a period of years largely determines whether an officer qualifies for staff college or war college, and influences his selection for promotion in the higher grades.

The British services use the qualification report system but also require a junior officer to qualify for promotion, and for attendance at staff college, by passing rigid examinations. The examination system is also used by the U.S. navy.

VII. CONCLUSION

An officer in a modern army, air force or navy has a responsible task. The lives of many of the nation's citizens depend upon his integrity, judgment and knowledge. Probably in no other field of endeavour is a leader thrust so quickly into a position of great responsibility as is the officer in time of war.

The officer is the product of his own nation's social system. But his colleagues in the armed forces of other countries share the difficulties resulting from the increasing complexity of modern warfare, and those of controlling human organizations in battle.

OFFSET, in architecture, is a slanting plane, forming a transition between a thin wall above and a thick wall below, or between varying depths of a buttress. An offset buttress is one deeper at the bottom than at the top, with the difference between the upper and lower faces taken up by one or more offsets.

OFFSET PRINTING: *see* LITHOGRAPHY.

OGADAI (UGEDEI or OGOTAI) (1185–1241), son and successor of the Mongol emperor Genghis Khan. He was chosen for the succession by his father because of the bad feeling between his two elder brothers, Jagatai and Jochi (who died in 1227). He was the first to call himself khagan (chief khan), his father having used only the title khan. Ogadai built a capital, Karakorum, in northern Mongolia, completed the conquest of north China (but not of China south of the Yangtze), and sent armies into Iran, Iraq, Azerbaijan and Russia. The Mongols destroyed many cities in Russia between 1237 and 1241. In the latter year they also defeated an army of Poles and Germans, marched through Hungary and reached the Adriatic sea. After these events Russia remained tributary to the Mongols of the Golden Horde, ruled by the descendants of Jochi, for more than 200 years. Following Ogadai's death his widow, Toragana, ruled as regent until 1246 when she handed over the throne to Kuyuk, her eldest son by Ogadai. *See* also MONGOL EMPIRES.

OGBOMOSHO, the most northerly of the principal towns of Western Nigeria, lies in Oyo province, 55 mi. N.E. of Ibadan and about 15 mi. from the border between Western and Northern Nigeria in the Ondo hills at about 1,200 ft. above sea level in an area of savanna and farmland. It is the third largest town of Nigeria. Pop. (1961 est.) 163,483.

The town extends over a large area astride the northward trunk road, which forms its main street. It is the headquarters of the American Baptist Church in Nigeria and has a notable theological seminary on "New England" architectural lines. The Ogbomosho mosque, with its great square tower, is a prominent landmark, and other churches and mosques rise among the walled compounds of private houses in traditional Yoruba and Nigerian "Brazilian" styles. Though there is no museum, fine wood carvings and Koso drums (unique to Ogbomosho) are found, mostly in private houses. There are a grammar school, a girls' high school and a teacher-training college; also Baptist and government hospitals, a tuberculosis clinic, a leper settlement and a home for motherless babies.

The town is a road junction and stands on the main road from Lagos (154 mi.) and Ibadan (55 mi.) to Ilorin and the north. To the southeast it is linked with Oshogbo and thence to Benin and Eastern Nigeria. Farming and trading are the principal occupations and local traders travel widely. Foodstuffs exported to other parts of Nigeria include yams, cassava and guinea corn; beans, palm oil and cotton are grown for home consumption. Tobacco is grown to supply the cigarette factory at Ibadan. The town is also an important staging point and market for cattle. Locally grown cotton is used for weaving the traditional Yoruba cloth, *aso oke,* while Ogbomosho weavers also make *sanyan,* a cloth woven from silk brought from Ilorin. The indigo dyeing of cloth is performed exclusively by the women. The craft of wood carving has declined.

More than 140 different communities found asylum in Ogbomosho during the former wars with the north and this accounted for its high population. Ogbomosho was founded as a camp about the mid-17th century and enjoyed peace until the early 19th century when the Fulani swept down from the north. Many of the surrounding Yoruba towns were destroyed, including old Oyo, the original Yoruba capital, but Ogbomosho resisted the invasion with the help of its walls, parts of which still remain. (W. H. I.)

OGDEN, CHARLES KAY (1889–1957), British writer and linguist, was the originator of Basic English (*q.v.*), a minimum language sufficient for general needs selected from English. At Cambridge, after a first class in the classical tripos (1910), he founded a penny intellectual weekly, *The Cambridge Magazine,* to which Hardy, Wells, Shaw and others contributed. In 1919 he made it a quarterly to print *The Meaning of Meaning,* a study in theory of language. The chapter on definition contained the germ of Basic English, which took final form in 1928. It consists of 850 head-words, few enough to be printed on a single sheet of note paper (rules in *The System of Basic English;* usage limitations in *The Basic Words*). The system became widely known and many books were printed in it (*e.g., The Basic Bible,* 1944). In 1943 Winston Churchill appointed a committee of ministers to study extension of its use. Ogden gave evidence before this body but the attempt proved premature. His own entry in *Who's Who* reads "1944–6, bedevilled by officials." Ogden died on March 22, 1957, in London. His work remains fruitful in improved conceptions of language learning. His great collection of books on Bentham and in language theory is in the library of University college, London.
(I. A. Rs.)

OGDEN, PETER SKENE (1794–1854), British fur trader who explored much of western America in the 1820s, was born of Loyalist American ancestry, probably in Quebec. About 1810 he entered the service of the North West company and was stationed at Isle-à-la-Crosse during the period of murderous rivalry with the Hudson's Bay company. Though excluded when the two concerns merged in 1821, Ogden was admitted as a chief trader in 1823, and for six years thereafter led the company's Snake country expedition in competition with American trappers. In 1825 he reached the river in Utah that now bears his name, explored southern Oregon and northeastern California in 1826–27, discovered the Humboldt river in 1828, and in 1829 made the first reconnaissance of the eastern face of the Sierra Nevada, discovering Carson, Walker and Owens lakes.

From 1831 to 1844 Ogden superintended trade in the British Columbia area, being made a chief factor in 1835. From 1845 to his death at Oregon City, Sept. 27, 1854, he was a principal officer in the Hudson's Bay company's Columbia department, warmly remembered for having succoured the survivors of the Whitman massacre (*see* WHITMAN, MARCUS). Ogden was twice married to Indian women, having children by each. He always remained a British subject. The anonymous *Traits of American Indian Life and Character by a Fur Trader,* published in London in 1853, is attributed to him. Abstracts of his journals, with a biography by T. C. Elliott, were published in the *Oregon Historical Quarterly,* 1909–10; the Hudson's Bay Record society began publishing the complete texts in 1950. *See* also OGDEN (Utah). (D. L. M.)

OGDEN, a city of north-central Utah, U.S., in the valley of the Great Salt lake, is located about 35 mi. N. of Salt Lake City; the seat of Weber county. A typical Utah garden city, green and tree-grown, Ogden sprawls near the foot of rough-hewn Wasatch mountain peaks on an old delta of the Ogden and Weber rivers which formed under the waters of ancient Lake Bonneville and slopes toward low-lying Great Salt lake. The Ogden river, from which comes the city's name, memorializes Peter Skene Ogden (1794–1854), a British fur trader who trapped in the mountains east of the modern city in May 1825. In 1846 the mountain man Miles M. Goodyear established Ft. Buenaventura, a log stockade with adjacent irrigated garden, on the site of Ogden, which gives the city the distinction of being the oldest continuously settled community in Utah; the "Goodyear cabin" is still preserved.

Goodyear sold out to the Mormons when they arrived in 1847, and early in 1848 Capt. James Brown of the Mormon battalion was sent to take over the Goodyear property. Brownsville, as it was called for a while, was renamed Ogden after Brigham Young laid out the town in 1849, the name being selected by the legislature in 1850. The city was incorporated a year afterward, and in 1951 adopted a council-manager form of government.

After the completion of the Union Pacific railroad in 1869, Ogden became the primary rail centre of the intermountain region and a major distribution point for manufacturing, milling, canning and agricultural products, its stockyards being particularly notable. Industries include the processing of food and dairy products and the manufacture of storage batteries, jet engines, clothing and building materials. State institutions located in Ogden include an industrial school for delinquent children and a school for the deaf and blind. Weber college, founded by the Mormon church in 1889 as Weber Stake academy, and turned over to the state in 1933, was expanded from a junior to a senior college in the 1960s. Pop. (1960) 70,197; standard metropolitan statistical area (Weber county) 110,744. For comparative population figures *see* table in UTAH: *Population*. (D. L. M.)

OGHAM WRITING. The Ogham alphabet (Old Irish *ogom*) was used for writing Irish and Pictish on stone monuments; according to Irish tradition it was also used for writing on pieces of wood, but there is no material evidence for this. It consists in its simplest form of four sets of strokes or notches, with five in each set, incised in the middle or on either side of the edge of an upright stone, thus giving 20 letters; a fifth set of five, called in Irish tradition "extra letters" (*forfeda*), seems a later development. The origin of this alphabet is in dispute, some scholars seeing a connection with the runic and, ultimately, with the north

SYMBOLS OF THE OGHAM ALPHABET, USED BY THE CELTS IN BRITAIN AND IRELAND

Etruscan alphabet, while others maintain that it is simply a transformation of the Latin alphabet evolved in Ireland; the fact that signs for *h* and *z* occur in it, but are not used in Irish inscriptions, speaks strongly against a purely Irish origin. The inscriptions are very short, normally consisting of a name and patronymic in the genitive case; they are of great linguistic interest because they show an older state of the Irish language than that attested by the earliest written sources. It is certain that many of them go back to the 5th and 6th centuries, but there are no epigraphic or linguistic criteria to prevent an earlier date being suggested for some of them. Their distribution is very uneven; of the 520 recorded by R. A. S. Macalister, 200 are found in the modern counties of Cork and Kerry, in southwest Ireland, and an exceptionally interesting group are the 37 from south Wales, nearly all of which are accompanied by Latin transliterations or equivalents. The key to the Ogham alphabet was never lost and it continued to be used as a kind of cryptographic writing (scholastic oghams) during the literary period. *See* also CELTIC LANGUAGES; IRISH LITERATURE.

OGIER THE DANE (OGIER LE DANOIS), an important character in the Carolingian cycle of French medieval epics. His historical prototype was Autcharius, vassal and liege of Pépin le Bref (Pépin III the Short) and subsequently of Pépin's son Carloman, the brother of the future Charlemagne. When Charlemagne, after Carloman's death (771), set out to annex his territories Autcharius in 771 or 772, accompanied Gerberga, Carloman's widow, and her two children to the court of Didier (Desiderius), king of the Lombards, and was with her when Charles captured Verona in 773. The fact that the French chronicles make no mention of Autcharius and that his existence is vouched for only by the *Vita Hadriani* in the *Liber Pontificalis* encourages the supposition that he was considered a rebel. All that is certain is that the *Gesta Karoli Magni* (*c.* 883) already asserts that he took refuge in Lombardy after incurring Charlemagne's wrath; it is also known that the monks of St. Faron at Meaux compiled, *c.* 1080, the *Conversio Othgerii militis*, an account of a great soldier who, with one of his companions, renounced the world to enter their monastery, and that before 1180 they had erected a tomb (still in existence in the 18th century) to their memory.

Though the *Chanson de Roland* (*q.v.*) and the *Nota Emilianense* speak of Ogier the Dane (named Oggero Spatha Curta—*i.e.*, "short-sword"—by the *Nota*) as one of the emperor's valiant warriors, many texts describe him as a rebel. The oldest of these appears to be that in the Danish *Karl Magnus Krønike* (before 1480), which relates that the pope, having summoned Charlemagne to aid him against the Saracens, was sent troops commanded by his son, Karlot, and Olger. Karlot, at first rescued by Olger, later disobeyed him and was finally killed by him in combat. Olger, condemned to three years' imprisonment, was only released when the emperor again needed his services. Charles and Olger were reconciled and Olger returned to Denmark. This narrative was recast, in whole or in part, first by Raimbert de Paris in his *La Chevalerie Ogier* (*c.* 1200–20), which includes Ogier's adventures in Italy and those relative to his reconciliation with the emperor, and then by Adenet le Roi (*q.v.*) in *Les Enfances Ogier* (*c.* end of the 13th century).

According to the *Chevalerie*, Ogier, in revolt against the emperor who had refused him justice after his son Baudouinet had been killed by Charlot, Charlemagne's son, swore an oath that he would kill Charlot in vengeance, and took refuge with the king of the Lombards, who appointed him his standard-bearer and gave him the strongholds of Montchevreuil and Castelfort. Charlemagne thereupon campaigned against Didier and Ogier, and defeated them; Ogier slew every Frenchman he encountered and fell back on Castelfort. There he was besieged for seven years. He escaped but was taken prisoner by Archbishop Turpin who handed him over to the emperor, who condemned him to death but left him in the archbishop's keeping. Turpin told Charlemagne that Ogier was dying of hunger, though he was secretly feeding him. News of Ogier's death was noised abroad; and the Saracens were emboldened to invade France, so that the harassed people bitterly deplored Ogier's disappearance. Turpin then revealed that Ogier was still alive, but Ogier refused to put himself at the head of the Christian troops unless Charlot was handed over to him. The emperor was forced to consent, but Ogier, as he unsheathed his sword to strike the young prince dead, was stopped by an angel who persuaded him that his oath would be fulfilled if he contented himself with slapping Charlot's face—which he did. Ogier then led the French into battle against the Saracens; he killed Bréhier, their leader, and was rewarded by Charlemagne with the gift, among other territories, of Hainaut and Brabant, and marriage to an English princess.

The development of these stories presents many points that remain unclarified, and Ogier's surname (the Dane), in particular, has not been satisfactorily explained (the *chansons de geste* make him the son of Gauffrey, king of Denmark). Ogier's adventures, however, became the subject of many medieval literary works. The third branch of the Norse *Karlamagnús saga*, the *Saga af Oddgeiri danska*, closely follows the narrative of *La Chevalerie Ogier*, but with greater order and concision. Ogier, called Otger Catalon, appears in stories describing the conquest of Catalonia. Under the name of Danés Urgel or Urgero, brother of the king of Dacia, he appears in three Castilian romances which were so popular in Spain that they were used by Lope de Vega in *El Marqués de Mantua*, written before 1604—a work of which Jerónimo de Cáncer's *La Muerte de Baldovinos* (1652) was a parody. In England, a later romance in alexandrines (British Museum Manuscript Royal 15 E VI) added supernatural elements derived from Celtic sources; the prose romance printed in Paris in 1495 was a version of this poem. In Italy this supernatural element was introduced

into stories of the hero's youth as well as of his manhood. The English romance is the basis of a poem in 47 cantos, *Uggeri il Danese*, several times reprinted between 1498 and 1638, as well as of a prose version; the French version is developed in a transcription in Franco-Italian, as well as in a Tuscan version of which there exist both a prose text and a text in *ottava rima*.

OGILBY, JOHN (1600–1676), British poet, translator and printer, a pioneer in the making of road atlases, was born in or near Edinburgh in Nov. 1600. His early career, as dancing master, tutor to the children of the earl of Strafford, with whom he went to Ireland (1633), deputy master of the Irish revels and successful proprietor of a Dublin theatre, ended when his finances were ruined by the outbreak of the English Civil War. Returning to England, destitute, he learned Greek and Latin and published translations of Virgil (1649), *Homer His Iliads* (1660) and *Homer His Odysses* (1665). At the Restoration, he won favour with Charles II and was entrusted with "the poetical part" of the coronation.

He returned to Ireland, where he opened another theatre, but subsequently settled in London and after the Great Fire of 1666, when he lost his property, was employed in surveying disputed [illegible] He set up as a printer with the title of "king's cosmographer and geographic printer" and produced many [illegible] for their typography and illustrations. His [illegible] . . . *a Geographical and Historical Description of the Principal Roads* (1675), which formed part of a projected world atlas, was based on his own journeys on foot, and was a landmark in accurate description of the country's roads. The maps were printed on strips, the first time this method had been used [illegible] He died in London, Sept. 4, 1676.

OGLETHORPE, JAMES EDWARD [illegible] British [illegible] gave him the [illegible] the poor [illegible] for such a colony in Georgia and arranged for the organization and financing of the undertaking. In 1733 he [illegible] In 1743 on his [illegible] he took part in the campaign against the Jacobites, but his slackness in pursuit of the retreating [illegible] brought him into disfavour with the duke of Cumberland [illegible] was tried by court-martial but acquitted. He then [illegible] liamentary career and saw no further active military [illegible] was promoted general in 1765 and became a prominent [illegible] in London and one of the friends of Dr. Johnson. He [illegible] Cranham hall, Essex, in 1785.

See A. A. Ettinger, *James Edward Oglethorpe* (1936). [illegible]

OGOOUÉ (OGOWE), a river of west central Africa, [illegible] almost its entire course through the Gabon Republic [illegible] Republic of Congo (formerly Middle Congo) on the [illegible] of the Chaillu range and enters the Atlantic south [illegible] It is about 970 km. (603 mi.) long and drains a basin [illegible] 85,000 sq.mi. At first it is a plateau river, but later [illegible] a valley which, in some places, spreads out into plains [illegible] river branches and, in others, narrows between escarpments [illegible] the Ogooué crosses the harder outcrops in a series of [illegible] way it flows from one basin to another, like that [illegible] upstream from the confluence of the Mpassa, and that [illegible] ville through which the Lolo also flows, parallel with the [illegible] before joining it. Below its meeting with the Ivindo the [illegible] turns westward and its course becomes more varied. [illegible] ing the Faré falls it forms a series of great rapids down [illegible] from its junction with the Ké and then divides into [illegible] are also broken by rapids as far as Ndjolé. Between [illegible] Ndjolé it is joined by the Offooué and the Okano. [illegible] it soon leaves the massif and crosses the lower G[illegible] ing joined by its chief tributary, the Ngounié, which [illegible] from the Chaillu range, above Lambaréné. [illegible] despite sandbanks, it is always navigable, its level [illegible] by Lac (Lake) Azingo to the north and lakes Onangué [illegible] to the south. A delta, formed chiefly of deposits [illegible] south by the cold Benguela current, spreads north of the main course.

The Ogooué has two flood seasons: March–June and [illegible] portant, November–December. Its average flow is 185,0[illegible] per second and it has plenty of water even during the low [illegible] August–September. It was formerly considered the [illegible] means of penetrating the interior from the Gabon coast. [illegible] person to explore the valley of the Ogooué was [illegible] (1857–59).

O'GRADY, STANDISH JAMES (1846–1928), [illegible] of letters, whose retelling of the Irish heroic [illegible] imagination of W. B. Yeats, T. W. Rolleston, Æ (George Russell) and others, and earned him the title of "father of the literary revival," was born at Castletown, County Cork, [illegible] 18, 1846. He graduated from Trinity college, Dublin. S. O'Halloran's *A General History of Ireland* (1778) [illegible] his interest in Irish antiquity; but it was Eugene O'Curry's *Manners and Customs of the Ancient Irish* (1873) and the author's *Lectures on the Manuscript Materials of Ancient Irish History* (1861) which gave him his first introduction to the heroic and romantic literature of Ireland. In 18[illegible] *Ireland: the Heroic Period* appeared and in 1880 it was [illegible] by *History of Ireland: Cuculain and His Contemporaries* [illegible]

The enthusiasm of Yeats and other young I[illegible] tually found O'Grady a wider audience and a [illegible] and in 1892 he published *Finn and His Companions* [illegible] two years later with *The Coming of Cuculain*. He also [illegible] eral works of historical fiction, of which *The Bog of Stars* and *The Flight of the Eagle* (1897) are prob[illegible] O'Grady's versions of Irish epic have great na[illegible] imaginative power and had a profound influence on Y[illegible] Irish writers of his time. He died at Shanklin, I[illegible] May 18, 1928.

O. HENRY: *see* HENRY, O.

O'HIGGINS, BERNARDO, (1776–1842), [illegible] Chilean independence and the head of its first national [illegible]

[illegible] Aug. 20, 1776, to an Irish father, Ambrosio O'Higgins [illegible] mother Isabel Riquelme at the village of Chillán [illegible] after advanced rapidly in the service of the Spanish [illegible] serving eventually as governor of Chile and viceroy of Peru, [illegible] headed a revolution against royal authority.

[illegible] in England, he read eagerly the revolutionary literature of the time and met various proponents of Latin-American independence, including Francisco Miranda (*q.v.*) of Venezuela. O'Higgins returned to Chile in 1802, he settled on his father's [illegible] in the southern part of the country and became an active [illegible] of a liberal organization which favoured independence. [illegible]'s invasion of Spain, which resulted in the dethronement of Ferdinand VII in 1808, encouraged a revolt in Chile, led [illegible] Martínez de Rozas and enthusiastically supported by [illegible]. Momentarily successful, this initial revolutionary effort [illegible] because of dissension among the patriots themselves and [illegible] opposition from viceregal headquarters in Peru. O'Higgins, who had advanced to the command of the rebel forces, was [illegible] defeated at Rancagua in Oct. 1814.

[illegible] and other patriots then fled over the Andes mountains [illegible] to join with the Argentine revolutionary leader José de San Martín, who planned to establish a base in Chile and then [illegible] the Spanish forces by striking at the centre of royal authority in Peru. This plan, launched in 1817 after careful but [illegible] preparations, was successful. In the course of the operations O'Higgins helped lead the revolutionary forces to victories [illegible] battles of Chacabuco in Feb. 1817 and Maipú in April 1818. [illegible] victories terminated Spanish authority in Chile, and the national independence was proclaimed on Feb. 12, 1819.

[illegible] served as supreme director of Chile, a virtual dictator from 1817 to 1823. Dedicated to the welfare of his country, [illegible] instituted reforms that aroused the opposition of the more [illegible] elements. The Roman Catholic Church objected to [illegible] to Protestants and his efforts to restrict the number [illegible] days. The landed aristocracy objected to his effort to [illegible] entailed estates. The importation of foreign books and the [illegible] on public instead of parochial education likewise drew criticism. Equally unpopular were his attempts to restrict [illegible], gambling and other amusements.

[illegible] opposition was able to force O'Higgins to resign in Jan. 1823. [illegible] the remainder of his life in Peru, where he died on Oct. 24, [illegible] remains were returned to his native land in Jan. 1869.

(W. D. Bz.)

O'HIGGINS, KEVIN CHRISTOPHER (1892–1927), [illegible] prominent in the troubled years following the [illegible] treaty of 1921, was born on June 7, 1892, at Stradbally, [illegible] county, the youngest son of Thomas Higgins. Educated at University college, Dublin, he became articled to his uncle [illegible] Healy, a solicitor in Cork. After the Easter rising in 1916 [illegible] the Sinn Fein movement and was interned. While still [illegible] was elected member of parliament for Queen's county in [illegible] the revolutionary *dáil* ministry set up in 1919 he acted as [illegible] for local government to W. T. Cosgrave. O'Higgins [illegible] the 1921 treaty with England that brought the Irish [illegible] being. He was appointed minister for economic [illegible] provisional government in Jan. 1922, and after the [illegible] Arthur Griffith and Michael Collins he became (1923) [illegible] of the executive council and minister for home [illegible] justice. O'Higgins was a member of the committee appointed [illegible] the constitution of the Irish Free State and he was [illegible] responsible for its passage through the *dáil* (lower [illegible] legislature). He created a new unarmed police force [illegible] Guards, and took strong, even ruthless, measures [illegible] order; his share of responsibility for the execution of 77 [illegible] 1922–23 was neither forgotten nor forgiven. In external [illegible] O'Higgins aimed at a united Ireland within the British [illegible] wealth. He played a prominent part in redefining commonwealth relations at the imperial conference of 1926. During [illegible] acute controversy over the taking of the oath of allegiance [illegible] members of the *dáil*, O'Higgins was waylaid by armed [illegible] on his way to Booterstown church, near Dublin, and [illegible] death (July 10, 1927). O'Higgins, a man of intellectual power and [illegible] were the primary [illegible] W. B. Yeats, who wrote of him as "a great man in the [illegible]" [illegible] IRELAND [illegible] *History*.

See T. de V. White, *Kevin O'Higgins* (1948). (P. N. S. M.)

O'HIGGINS, [illegible] province of central Chile. [illegible] 2,745 sq.mi. and the population in 1960 was 259,700. Named after Bernardo O'Higgins, [illegible] in the war of independence and first president of Chile, the province was formed in 1883, dissolved in 1927 and created again in 1934. Its departments are Rancagua, Caupolicán, San Vicente and Cachapoal.

Most of the western [illegible] O'Higgins lies in the alluvial plains of the central valley, where because of the [illegible] dry season of summer irrigation is required. Water is furnished by streams that have their sources in the snow-capped Andean cordillera. The highlands and the [illegible] support cattle and some sheep. Irrigated pastures are widely used for dairy herds and to ready beef cattle for market. Grapes, wheat, barley, legumes and corn are the principal crops. [illegible] and the provincial capital, Rancagua, pop. (1960) 53,[illegible], are the [illegible] marketing centres for O'Higgins producers.

Rancagua is 51 mi. S. of Santiago on the railroad to Puerto Montt; it is the terminus for a branch line to the intensively farmed Doñihué and Coltauco districts. A second branch line extends westward from near Rengo (10,989), a departmental capital, to serve the smaller administrative and agricultural towns of San Vicente de Tagua-Tagua and Peumo. The paved north-south highway and a number of all-year roads provide the province with good transportation facilities. There are mineral spring resorts at Termas de Cauquenes, southeast of Rancagua, and at Cachantún, southwest of the city. Rancagua, founded in 1743, is the site of a famous battle (Oct. 1–2, 1814) in the war of independence. Among its industries are the shops and foundry of the copper company, grain mills and a glass factory. Rengo manufactures matches and hardware. El Teniente, the second largest copper mine in Chile, is also located in the province. (J. T.)

OHIO, a north-central state of the United States, is bounded on the north by Michigan and Lake Erie, on the east by Pennsylvania and the Ohio river, the [illegible] boundary of the river separating Ohio from West Virginia and Kentucky, and on the west by Indiana. [illegible] is measured by its dimensions [illegible] mi. and [illegible] mi. Its area of [illegible] sq.mi. in Lake Erie and [illegible] sq.mi. of inland water surface. [illegible] Although [illegible] Ohio [illegible] first to be carved from the Northwest territory [illegible] "Buckeye state" [illegible] cardinal and the [illegible] the state flag [illegible] burgee shape [illegible]. The great seal of the state of Ohio [illegible] in the background, and [illegible] in the foreground.

PHYSICAL GEOGRAPHY

Physical Features.—Like its [illegible] Ohio's topography is a composite. [illegible] between [illegible] N. lat. and between [illegible] W. long. The [illegible] of the great glaciers of the Ice Age was largely responsible for Ohio's physical [illegible] as the ice sheets spread over the state [illegible] and created a flat or gently rolling surface noted for its fertility. The southeast, beyond the glaciers' penetration, is characterized by steep elevations, deep valleys and [illegible]

Much of this section has been relatively unexploited.

Its singular location endowed Ohio with the characteristics of three different physiographic provinces—the Lake plains, the Central plains (or central Lowland), and the Allegheny plateau. The juncture of the three sections is near Cleveland, but the last two abut approximately through the centre of the state, north to south. The Lake plains area, encompassing northwest Ohio and a strip along the Lake Erie coast, was once entirely under water. It emerged monotonously flat and swampy, and not until drainage projects were successfully undertaken in the late 19th century could its fertile soil be used to good advantage. The Central plains embrace the western and southwestern counties. Having undergone much erosion prior to the coming of the glaciers, this area was consequently rather uniformly covered by the vast ice sheets, creating a comparatively level surface with soil of considerable depth. To the east, the Allegheny plateau includes both glaciated and unglaciated areas. The counties lying south of the terminal moraine (the limit of the glaciers' advance) lack the arable soil and the extensive pasture lands of the counties of the north and west. On the other hand, the unglaciated regions offer rugged and spectacularly beautiful terrain noted especially for caves, precipitous valleys and breath-taking rock formations.

Ohio's average elevation above sea level is approximately 850 ft. The extremes, both of which occur in the Central plains, are 1,550 ft., near Bellefontaine, and 433 ft., on the Ohio river bank near Cincinnati. Most of the state rises to between 550 and 1,300 ft. in elevation.

A notable topographical feature of Ohio is the watershed which traverses the state from the middle of the western boundary to the northeast corner. Above the watershed, rivers flow north into Lake Erie. They are short and their courses are not parallel. Below it, the rivers flowing south to the Ohio river are about three times as long as their counterparts to the north, and they drain about 70% of the state's surface. Several gaps in the divide facilitated the development of transportation and, with the aid of easy portages, made possible important north-south water routes employing the Maumee and Miami rivers, the Sandusky and Scioto rivers, and the Cuyahoga-Tuscarawas and Muskingum rivers. Of lesser significance are the Huron, Vermilion and Black rivers in the north, the Olentangy, Licking, Hocking and Little Miami in central and southern Ohio, and the Grand and Mahoning in the east. The Ohio river flows for about 435 mi. through a narrow valley along southeastern and southern Ohio but it is not legally within the boundaries of the state. At various times the Ohio and some of the interior rivers have overflowed their banks, causing disastrous floods. So great a catastrophe occurred in 1913, especially at Dayton, that Ohio took steps to prevent a recurrence of the tragedy by establishing the Miami conservancy district (and later the Muskingum conservancy district). The 1914 law authorizing this action, which consisted basically of constructing a series of dams to control streams in their upper reaches, was the first of its kind in the United States. The federal government built 19 dams on the Ohio river which have also substantially reduced the flood threat. A few serious floods have occurred since 1913 but their effects have been greatly mitigated by the existence of the dams.

Excellent natural harbours have helped to make Toledo, Sandusky, Lorain and Cleveland important lake ports. In the state are more than 100 lakes exceeding 40 ac. each in size. Twenty-seven of these are natural while the rest were man-made, some of them constructed originally as canal reservoirs. The latter include 16,000-ac. Lake St. Marys (Grand Reservoir), Lake Loramie, Indian lake and Buckeye lake.

Climate.—The principal characteristics of Ohio's climate are its changeability and its extremes of temperature. The result is a seasonal variation which to some extent compensates for extremes of heat and cold, high humidity and the like. The average annual temperature is a moderate 51.2° F., with the northern section at 49° about 6° lower than the southern. In the summer, of which July is usually the hottest month, the temperature averages 71.6°, and in the winter 29.8° with January customarily coldest. The recorded extremes of −39° at Milligan in Feb. 1897, and of 113° near Thurman in July of that year and at Gallipolis in July 1934, are seldom closely approached, but it is not uncommon for the temperature to vary as much as 100° within a year. Precipitation, averaging about 38 in. per year, is slightly heavier in the summer. The 21-in. average for the six months commencing April 1 exceeds that of the rest of the year by 4 in. The south receives 44 in. of rain, snow, etc. in an average year as compared with 32 in. in the north. The average annual snowfall presents a greater contrast; only 15 in. in the southern counties, it reaches 40–45 in. in the northern, producing a state-wide average of 27.8 in. Farmers usually can expect a growing season of 150–180 days, with those close to Lake Erie enjoying nearly 200 frost-free days.

Soil.—The nature and quality of the soil differs markedly between one section of the state and another. The southeast, which was deprived of the deep and fertile drift deposited by the glaciers and in which the soil is largely residual sandstone and shale, is the least arable and productive. The glacial sandstone soil of central and northeastern Ohio supports some general farming but is best suited to grazing and pasture lands for the important dairy industry. The soil of the lower two thirds of the western half of the state, composed principally of glacial limestone, is the richest of all. To the north lies the second most prosperous agricultural area. There, after the vast swamps had been drained, the limestone soil was found to be highly productive.

Vegetation.—Dense forests formerly covered nine tenths of Ohio. Early explorers and woodsmen, as well as the first generation of settlers, literally disappeared from view after they crossed the Ohio river. So thick were the trees that for many years wisps of smoke rising here and there through the leafy overhead were the only visible signs of habitation. The most prevalent types were beech, oak, hickory, maple and chestnut, with others, especially pine, elm, ash and buckeye, occurring in smaller numbers. The forests which yielded the timber for buildings and furniture, fences and fuel, at the same time presented a serious obstacle to the settler's search for a livelihood through farming. Countless trees were burned to clear the land. Some of these have been replaced by second-growth trees, of which the commonest are oak, hickory, white elm, ash, beech, maple, willow, sycamore and yellow poplar. Most of the approximately 15% of Ohio that is woodland is set aside in protected preserves. Twenty of these are state forests, of which 35,000-ac. Shawnee State forest near Portsmouth is the largest. In addition to trees, both wild and domesticated flowers thrive throughout the state.

Animal Life.—Although some animals and birds common to Ohio as recently as the 19th century have since become extinct, at least 60 species of wild animals and about 175 species of songbirds still occur in significant numbers. Most of the animals are small—*e.g.*, rabbits, squirrels, foxes, raccoons, opossums and skunks—but there have been increasing numbers of some larger animals, including deer. Represented among the songbirds and birds of prey are most of those normally found in the temperate zone. So abundant are the 170 kinds of fish, among them bass, trout, pike, perch and muskellunge, that Ohio became the first state to remove all restrictions on fishing as to season and number and size of fish caught.

Parks.—Ohio has two national monuments: Perry's Victory monument at Put-in-Bay and the 68-ac. prehistoric Mound City group north of Chillicothe. State parks include historic, archaeological and natural history sites administered by the Ohio Historical society, as well as recreational facilities under the department of natural resources and the highway department.

Historic Sites and Museums.—Many historic sites are preserved and maintained by historical societies or other organizations. Stressing variously exhibit museums, historic buildings, research libraries and publications, numerous counties support historical societies, of which the best-known are those of Ross, Allen, Stark and Lucas counties. Of regional significance are the Western Reserve Historical society at Cleveland and the Historical and Philosophical Society of Ohio at Cincinnati. The state-supported Ohio Historical society has headquarters at the Ohio State museum at Columbus. The museum itself houses exhibits and extensive collections related to Ohio history, archaeology and natural

[illegible] and a specialized research library of more than 1,000,000 [illegible], books, periodicals, newspapers and maps. There [illegible] the *Ohio Historical Quarterly* and other peri[illegible] leaflets and books. The society administers 60 properties [illegible]out Ohio, including the birthplaces or residences of Thomas [illegible]on at Chillicothe, William T. Sherman at Lancaster, [Ruth]erford B. Hayes at Fremont, Ulysses S. Grant at Point Pleas[ant, Benj]ain R. Hanby at Westerville, and Paul Laurence Dun[bar at] Dayton. "Adena" at Chillicothe, "Glendower" at Lebanon, [the] McCook house at Carrollton are interesting architectural [illegible]. Reconstructed Schoenbrunn village and Gnadenhutten [illegible] pay reverent tribute to the Moravian missionaries and [their] Indian converts. The Indian wars are commemorated at [Forts] St. Clair, Jefferson, Recovery, Meigs and Miami and at the [site of] the battle of Fallen Timbers. Other historical state memo[rials ran]ge from the Friends' Yearly meetinghouse at Mount Pleas[ant to] the site of the battle of Buffington Island (July 19, 1863). [In addit]ion to the famous glacial grooves on Kelleys Island, the [natural] history areas include Cedar Swamp, Fort Hill and Flint [illegible]. Prominent among the archaeological sites are Ft. Ancient, [the] Serpent mound, Newark earthworks and Inscription rock on [Kelleys] Island.

The state is unique in the diversity of museums devoted to [transpor]tation. Automobiles are featured at the Thompson Auto[mo]tive museum at Cleveland (besides private collections), aircraft [at] the Air Force museum at Dayton, steamboats and other river [craft] at the River museum at Marietta, lake vessels at the Great [Lakes] Historical society's Wakefield museum at Vermilion, and lo[comot]ives, interurbans and streetcars (some operating over nearly [illegible] of track) at the Ohio Railway museum at Worthington.

HISTORY

Prehistory.—In Ohio have been found identifiable remains of [illegible] migrants who developed a culture known as the Archaic ([see] ARCHAEOLOGY: *Anglo-America: Archaic*). Dwelling prima[rily] along rivers, these people appeared in the western hemisphere [some] 5,000 to 7,000 years ago. They led a sedentary life and [produce]d artifacts fashioned from bone, shell, flint and antler, [but] did not engage in agriculture and made little pottery. Archaic [man] was the first of a series of prehistoric peoples whose occu[pation] of the Ohio region has been conclusively established. The [illegible] succeeding groups have been designated the Adena, Hope[well and] Fort Ancient cultures. From 1901 when the Adena cul[ture] was first discovered near Chillicothe, many other examples [have] been located in the state. Intensive study of such evidence [has ena]bled archaeologists and anthropologists to construct a re[veal]ing picture of the Adena people. They had flat heads, deliber[ately f]ormed in infancy, but they were more robust than their [illegible] predecessors. That they possessed more artistic skill is [evident] in the pottery and in the copper and mica ornaments [they] made. They cultivated certain vegetables, constructed cir[cular] dwellings and erected burial mounds which have inspired for [them] as well as for other prehistoric peoples the name Mound [Builders]. The Adena culture can be traced to as early as 800 B.C. [The t]erminal date for the Adena culture is A.D. 800, while the ex[tent of] the Hopewell culture which followed it range from [illegible] to A.D. 1500. The Hopewell Indians not only hunted, [illegible] and traded with other peoples, but they made and [placed] in their mounds exquisitely carved pipes and expertly [fashione]d ornaments of mica, copper, pearl and shell. The most [striking evi]dence of their culture outside of museums is the number [of re]markable effigy mounds and other earthworks they con[struct]ed. Among those still standing are Ft. Ancient in Warren [county] [and] the Newark earthworks in Licking county. (See also [HOPE]WELL; MOUND BUILDERS.)

The Hopewell people represented the apex of prehistoric cul[tural at]tainment in the Ohio valley. When they disappeared, they [illegible] Indians about whom surprisingly little is known [illegible] designated Late Woodland. For [illegible] years or [illegible] the arrival of European explorers in the Ohio re[gion] [illegible] surviving into the historic period, a people [called Fort] Ancient occupied parts of Ohio. This name has given rise to considerable confusion because the Ft. Ancient earthworks, as mentioned above, were actually built by the Hopewell and not until later occupied by the so-called Fort Ancient people. One well-supported theory is that the Shawnees were immediate descendants of the Fort Ancient group.

The French and British, upon penetrating the Ohio valley, found Indians representing four major tribes and several lesser ones. Dominating the region were the Miamis, Shawnees, Wyandots and Delawares, but they shared the scene to some extent with the Eries, Ottawas, Tuscaroras and Mingoes, or Senecas. These tribes produced some of the most famous American Indian warriors and statesmen, among them Tecumseh, Blue Jacket and Cornstalk (all Shawnee); Tarhe the Crane (Wyandot); Little Turtle (Miami); Buckongahelas (Delaware); and Pontiac (believed by some to have been an Ohio-born Ottawa). The Indians, who numbered a probable maximum of 15,000 in Ohio in the mid-18th century, resisted white settlement. Their opposition decreased after their defeat in the battle of Fallen Timbers (1794). Most tribes had departed from Ohio well before the final exodus of the Wyandots in 1842.

Exploration and Settlement.—A young Frenchman, René Robert Cavelier, sieur de La Salle, is generally acknowledged to have been the first white man to explore the Ohio country. La Salle set out from his estate near Montreal in 1669 to journey into the country south of Lake Erie. This exploration provided the basis for a French claim to the Ohio valley which was hotly contested by Great Britain through much of the following century. British assertions of ownership, as time went on, were predicated upon the increasing activity of traders. By their royal charters, which were sometimes contradictory, several colonies were granted all or part of this region. Virginia, for example, laid claim to a fan-shaped area stretching to the Pacific ocean and encompassing all of the Ohio country. Pennsylvania's charter, on the other hand, [illegible] part of the Ohio country as being under that colony's jurisdiction. The French and British competed not only for control of the land but also for the favour of the Indians. In [illegible] France took the initiative by sending Pierre Joseph de Céloron de Blainville down the Ohio river, along which he buried, at intervals, lead plates claiming French ownership. He returned to the St. Lawrence by way of the Great Miami and Maumee rivers and Lake Erie. His journey had little practical effect, however, and English traders continued their operations there. Moreover, a Virginia group known as the Ohio company in [illegible] sent Christopher Gist, a veteran woodsman and trader, into and across Ohio to the Miami river town of [illegible]. The diary Gist wrote, which has come to be regarded as one of the most important [illegible] early Ohio, provided the information his employers sought relative to the nature of the country and the Indians. His mission also aroused the [illegible] of the [illegible] traders and [illegible] of the Indians who were apprehensive of white interest in their lands. The [illegible] French rivalry grew more [illegible] during the [illegible] dispatched from Virginia in 1753 and [illegible] by George Washington [illegible] French [illegible] through the Ohio valley. Governor Dinwiddie ordered [illegible] on the site of present Pittsburgh (Feb. 1754). [illegible] French forces [illegible] Ft. Duquesne. A de[tachment of French s]oldiers was surprised and captured at Great [Meadows by Virginia troops under] Washington's command [illegible] shortly thereafter [illegible] to surrender to a larger force [illegible] the French [illegible] of the Ohio valley. This series of events [illegible] the French and Indian War [illegible]. The British [illegible] the opposition of the French and their Indian allies [illegible]. By the terms of the treaty of [illegible] France [illegible] to England its claims to Canada and the eastern half of the Mississippi valley. One of the decisive events of the war had been the [illegible] Ft. Duquesne which the British renamed Ft. Pitt for William Pitt whose brilliant statesmanship was partly responsible for the ultimate victory.

Although the French threat in eastern North America had been

removed, the Indians in this territory continued to pose a serious problem. Uniting under the leadership of the Ottawa chieftain, Pontiac, they launched a campaign in 1763 which resulted in the capture of several forts and which was broken finally by the successful defense of Detroit and Ft. Pitt. In the following year the appearance of Col. Henry Bouquet with 1,500 men at the site of present Coshocton so impressed the Indians that they agreed to terms and released more than 200 captives, some of whom had been prisoners since childhood. Anxious to prevent further trouble with the Indians and to deter the expansion of the American colonies, England issued the Royal Proclamation of 1763 forbidding settlement west of the Alleghenies. This and other acts and policies during the next decade contributed to the resentment which culminated in the American Revolution. The victory of the colonies brought not only recognition of independence but also theoretical possession of the lands east of the Mississippi. It remained for physical control to be asserted. Although not a major battleground during the American Revolution, the Ohio country was caught up in the maelstrom of Indian raids against Kentucky and Pennsylvania and retaliatory forays by Americans. It is a tragic footnote to history that the greatest atrocity of the war (and one of the most brutal massacres of all time) was perpetrated in Ohio by Americans. The Moravian Brethren, led by David Zeisberger, John Heckewelder and others, had been active in the 1770s in bringing Christianity to the Ohio Indians, primarily the Delawares. They established missions which became small Christian Indian villages, the original one in 1772 being Schoenbrunn, near present New Philadelphia (*q.v.*). Because of their pacifism and neutrality, these Indians were viewed with suspicion by both the Indians who sided with the British and the American frontiersmen. At length the converts were removed to the Sandusky region and made virtual prisoners of the Wyandots living there. Facing starvation, however, a group of them was permitted to return to the Tuscarawas river in northeastern Ohio to gather the corn they had abandoned in their fields. They were so engaged on March 7, 1782, when Capt. David Williamson and about 90 volunteer militiamen, mostly from the Pittsburgh area, arrived on the scene. Seeking revenge for recent depredations committed by other Indians, the Pennsylvanians held a kangaroo court and decreed death for the innocent Indians. The next morning, at the settlement of Gnadenhutten, the prisoners were led from their cabins in pairs and slaughtered in cold blood. Only two boys escaped the fate that befell 62 adults and 34 children. As two leading authorities on Ohio history have expressed it, "the murder by a band of frontiersmen, supposedly Christians, of a group of noncombatant neutrals who had been taught to regard nonresistance as a Christian virtue is almost without parallel" in the annals of warfare. (E. H. Roseboom and F. P. Weisenburger, *A History of Ohio*, new ed. [1953], courtesy The Ohio Historical Society.) Although Cornwallis had surrendered at Yorktown six months earlier, this massacre touched off what became known as "the bloody year" in the Ohio country. Of the incidents that followed, perhaps the most memorable was the capture of Col. William Crawford who had been elected by popular vote to carry the fight into the interior of Ohio. His command included many of Williamson's men whose presence aroused the Indians. The latter not only repelled the invasion but also captured Crawford whom they tortured unmercifully and burned at the stake in June 1782. The end of hostilities, though not the end of Indian resistance, came six months later.

The Northwest Territory.—Great Britain's cession of the area south of the Great Lakes and east of the Mississippi left the U.S. government faced with the complicated problem of providing for systematic settlement and administration. The situation was further muddled by the conflicting claims laid by several of the individual states upon the region (the Northwest territory, as it was to be designated, or, more formally, the Territory Northwest of the River Ohio). The other states demanded that title to these lands be transferred to the national government before they would agree to ratify the Articles of Confederation in 1777. New York was the first to comply, in 1780 (its claim was the most tenuous), followed by Virginia in 1784, Massachusetts in 1785 and Connecticut in 1786. Certain small areas were reserved, however, to be granted to war veterans, principally the Virginia military tract in southern Ohio and Connecticut's Western Reserve in the northeast. Two legislative measures of fundamental importance completed the foundation for the development of Ohio. These were the Land ordinance of 1785, establishing a system of surveying the land into six-mile square townships, and the Ordinance of 1787 (the Northwest ordinance), providing that a territorial government would at first administer the region, which would ultimately enjoy representative government and finally be divided into at least three but not more than five states. The pattern of settlement that followed gave Ohio a rather conglomerate population. From New England came members of the second Ohio company (*q.v.*), recently formed, who disembarked at the confluence of the Ohio and Muskingum rivers in April 1788, and founded Marietta, the state's oldest permanent settlement. This became the seat of the territorial government with the arrival three months later of Gen. Arthur St. Clair, the first governor of the Northwest territory. New Englanders, largely from Connecticut, also settled the Western Reserve, beginning with Cleveland in 1796. Meanwhile, Judge John Cleves Symmes of New Jersey headed a combine which secured a grant of approximately 250,000 ac. on the Ohio river between the Great Miami and Little Miami rivers. Cincinnati (1789) was destined to become the most important settlement in the so-called Symmes purchase. To the Virginia military tract, lying between the Scioto and Little Miami rivers, came growing numbers of Virginians, founding first Massieville in 1790, then Chillicothe in 1796 and ultimately other towns. This district would soon achieve great prominence in the development of Ohio. In addition to these relatively large groups of settlers, Ohio was peopled by Kentuckians from across the river, Pennsylvanians who moved westward, and even a sizable band of French citizens, who landed on the bank of the Ohio in 1790 and found a primitive wilderness instead of the promised civilized metropolis; they adapted to the rigorous conditions and carved out the town of Gallipolis (*q.v.*).

The treaty of Paris in 1783 removed neither of the menaces confronting Americans in the northwest. The British refused to withdraw their troops from the forts at Detroit, Sandusky, Michilimackinac and other posts on American soil. Their justification rested upon the nonpayment of private American debts to English merchants in accordance with the terms of the treaty. Continued occupancy of the forts was much to their advantage since it gave them control over the lucrative fur trade as well as the Indians who already were hostile toward the westward-moving Americans. The British finally evacuated these posts as a result of the treaty negotiated by John Jay in 1794, but by that date the Indian threat had been disposed of by the use of American arms.

Treaties made before 1790 with various more peaceful tribes were of little avail, for the bellicose Shawnees and others contended that no pact was binding unless acceptable to all the tribes. The increasing audacity of the Indians in their raids against the settlers prompted congress in 1790 to authorize the president to send the militia from Virginia, Kentucky and part of Pennsylvania to Ft. Washington at Cincinnati to launch a punitive campaign. In that year Gen. Josiah Harmar led a poorly trained and ill-equipped army as far as the site of present Fort Wayne, Ind., burning several Indian villages, but a third of his force was routed in encounters with the enemy. Harmar was exonerated personally but he was superseded in command by Gov. St. Clair in 1791. St. Clair had partially executed his plan of erecting a series of forts between the Ohio river and Lake Erie when at dawn on Nov. 4, 1791, Indians led by Little Turtle attacked without warning and decimated St. Clair's garrison. The assignment went next to Maj. Gen. Anthony Wayne, a Revolutionary War hero who had later fought the Creeks in Georgia. Wayne arrived at Cincinnati in the spring of 1793 with 2,500 men. Determined to instill discipline and to prepare his men for frontier fighting, he trained them for months before moving northward late in the year. While wintering at the newly erected Ft. Greene Ville, Wayne ordered construction nearby of another stockade, which was to be called Ft. Recovery, upon the site of St. Clair's defeat. When the British

rebuilt Ft. Miamis in 1794, Wayne countered with a new fort, appropriately named Defiance, at the junction of the Auglaize and Maumee rivers. A decisive battle put an end to the Indian menace in Ohio and opened the land to settlement. At Fallen Timbers, a site above the present city of Maumee, where numerous trees, toppled by a hurricane two years earlier, afforded the Indians effective cover, Blue Jacket waited with more than 2,000 warriors. There in less than one hour on Aug. 20, 1794, the issue was resolved, for Wayne's thoroughly trained force charged through the brush, broke the Indians' left flank and left them demoralized and beaten. Further resistance was halfhearted and ineffectual, and on Aug. 3, 1795, more than 90 Indian leaders met with Wayne and other representatives of the United States and signed the treaty of Greenville. By its terms hostilities ceased and the Indians surrendered all of the territory east and south of a line extending from the Ohio river opposite the mouth of the Kentucky north to Ft. Recovery, east to a point above Ft. Laurens, and north to Lake Erie. This treaty, a milestone in the nation's early history, was honoured by the vanquished Indians until Tecumseh went on the warpath in the War of 1812. The Indian capitulation, coupled with the provisions of Jay's treaty, at long last gave the United States actual as well as nominal jurisdiction over land it had owned since 1783. In the next quarter of a century the Indians relinquished, either by cession or by sale, the remainder of their lands in Ohio.

Statehood.—Wayne's victory so expedited immigration into the Northwest territory that Ohio's population had reached 45,365 by 1800. Meanwhile, in accordance with the Ordinance of 1787, representative government had been achieved in 1799. The lower house of the legislature consisted of 22 elected members, 15 from the counties which would ultimately become Ohio and the others from the rest of the territory. From the names submitted by the lower house, Pres. John Adams chose five to constitute the council, or upper house. St. Clair continued as governor with curtailed authority, and the first territorial delegate to congress was William Henry Harrison. Since the population requirement for statehood was only 60,000, attainment of this goal, although it was opposed by St. Clair, appeared imminent. St. Clair's determination to forestall Ohio statehood stemmed in part from his Federalist beliefs as opposed to the strong Republican tendencies prevailing among the people of the territory. He proposed a division of the territory through the Scioto valley, the stronghold of Republicanism, with seats of government at Marietta and Cincinnati and a third probably at Vincennes. St. Clair's plan was doomed, for the pro-statehood faction, led by Thomas Worthington and Edward Tiffin of Chillicothe, former Virginians, enlisted the support of Pres. Thomas Jefferson, and congress passed an Enabling act, signed by him April 30, 1802. The 35 delegates to Ohio's first constitutional convention met at Chillicothe on Nov. 1 and after only 25 days emerged with an instrument of government for the new state. The legislature convened for its initial session on March 1, 1803, the year usually regarded as the one in which statehood was actually achieved. Because it had never been so designated officially, however, the U.S. congress by joint resolution in 1953 (Ohio's sesquicentennial year) declared March 1, 1803, to be the date of Ohio's admission as the 17th state of the union. The Jeffersonian Republicans dominated the new government, with Tiffin becoming the first governor and Worthington joining John Smith of Cincinnati as the first Ohioans to sit in the U.S. senate. Jeremiah Morrow of Warren county was Ohio's lone representative in the house for five consecutive terms. The state government was established at Chillicothe, where the new state house was the first public building constructed of stone in Ohio. Apparent political chicanery moved the capital to Zanesville from 1810 to 1812. It returned to Chillicothe in the latter year but was permanently located in 1816 in the centrally located, newly platted town of Columbus.

Ohio's early history is studded with noteworthy events, some to be recalled in later years with greater pride than others. The strange and seemingly nefarious scheme of Aaron Burr, the discredited former vice-president, inspired great excitement in 1806. Using Blennerhassett Island in the Ohio river below Marietta as a base of operations, Burr mustered a small expeditionary force which aroused the suspicions of the state government. The militia was called out and boats and supplies were confiscated. The Virginia militia wrecked Harman Blennerhassett's island mansion but Burr had moved on to the southwest; he was eventually returned and tried for treason.

The War of 1812.—Ohio's geographical position gave it a degree of importance in the War of 1812. Indignant over Gen. William Hull's ignominious surrender of Detroit to the British in 1812, forfeiting control of Lake Erie and the Michigan country, and over Gen. James Winchester's disastrous defeat at the Raisin river (Monroe, Mich.) in Jan. 1813, Ohioans turned to Gen. William Henry Harrison for a restoration of American prestige. Harrison had added to his public stature two years before by a foray at Tippecanoe creek (Indiana) against Indians united under Tecumseh who, however, was absent at the time. In 1813 Harrison successfully endured a British siege of Ft. Meigs at the mouth of the Maumee river and Maj. George Croghan with one cannon and 150 men withstood an enemy assault upon Ft. Stephenson on the Sandusky river, but it was still impossible to mount an offensive until control of Lake Erie could be wrested from the British. This was accomplished in Sept. 1813, by the victory of Oliver Hazard Perry's small fleet at the battle of Lake Erie, off Put-in-Bay. Harrison pursued the advantage by invading Canada, where he registered a decisive conquest in the battle of the Thames a few weeks later. The death of Tecumseh in this battle signaled the end of the Indians' organized support of the British, and the United States controlled the west throughout the balance of the war.

The fledgling state, suffering the effects of the postwar depression, attempted to tax the Bank of the United States out of existence in Ohio in 1819. Despite the precariousness of its position because of the U.S. supreme court's affirmation of the bank's constitutionality in *McCulloch* v. *Maryland*, Ohio imposed an exorbitant tax. The case was eventually argued before the supreme court by some of the most brilliant lawyers of the day. The 1824 decision upholding the bank in *Osborn* v. *Bank of the United States* ended Ohio's venture into the field of nullification, but by that time the issue had lost much of its practical significance.

Internal Improvements.—A more judicious remedy for the economic hardships of the time (although some questioned its wisdom also) was the launching of an extensive canal system within the state. An ardent leader in the movement for internal improvements, Gov. Ethan Allen Brown (1818–22) crystallized favourable sentiment and badgered the general assembly into establishing a canal commission. He served on this commission and later on the canal fund commission which negotiated loans and disbursed money during the period of construction. Brown's role was so important that he became known as the "father of the Ohio canals," a title sometimes also bestowed upon Alfred Kelley who supervised much of the actual digging. Gov. DeWitt Clinton of New York helped to officiate at ground-breaking ceremonies near Newark on July 4, 1825. Two years later the first section of the Ohio canal was put into use and before long traffic on the entire 308-mi. waterway between Cleveland, on Lake Erie, and Portsmouth, on the Ohio river, was bringing prosperity to every locality along its route. In addition to feeders and several shorter canals, another major canal was built in the western part of the state. This, the Miami and Erie canal, joined Cincinnati and Toledo via the Miami and Maumee valleys. Ohio's canal building program was extremely costly and eventually the "ditches" were superseded by railroads, but they rescued the state from the financial doldrums of the 1820s and they were of primary importance at least until mid-19th century. Without them, the state's agricultural and commercial development would have been seriously impeded.

The American Civil War.—The second quarter of the 19th century witnessed the passing of the frontier and a growth in the number and size of towns. It was marked also by an occasional flurry of excitement, such as the Toledo war, a dispute with Michigan over the boundary between the two states. A dominating influence during this period was the worsening conflict over slavery and abolition. Ohio's zealous antislavery sentiment resulted in

disaffection from the Democratic party (the old Jeffersonian Republicans) at the end of the Jackson era, and the Whigs gained the upper hand for a time. In 1841 William Henry Harrison, a native of Virginia but long identified with Ohio, became the first president from the state. The 1850s found many constituents in Ohio for the Free-Soil and then the new Republican parties, and the state played a significant role in the Civil War. Besides furnishing such statesmen as Edwin M. Stanton and Salmon P. Chase and such military figures as Grant, Sherman and Sheridan, Ohio sent nearly 350,000 men into the Union army. Opposing the war effort were the "Copperheads" (*q.v.*) of whom the most prominent was Clement L. Vallandigham of Dayton. Although in exile, he was nominated for governor by the Peace Democrats in the critical election of 1863. His overwhelming rejection by the voters inspired President Lincoln's assertion that "Ohio has saved the Union." The only time the war actually crossed the Ohio border was in July 1863, when Confederate Gen. John H. Morgan and 2,500 men commandeered two steamboats to ferry them from Kentucky to Indiana, swept across the southeast section of the latter state and eastward through Ohio. From the time Morgan's cavalry passed through Cincinnati's suburbs, rumour ran rampant as to his objective. Fanciful assumptions to the contrary, his primary aim apparently was to create a diversion and to lessen the military pressures elsewhere. The column rode across southern Ohio, indulging in looting and some destruction along the way but refraining generally from the type of wanton depredation common to such invasions. Morgan's plan to recross the Ohio at Buffington Island was thwarted by the arrival of the pursuing Federal cavalry. From the battle that ensued, Morgan extricated 1,200 men. They staged another attempt to ford the river 20 mi. upstream but only one fourth of the force had negotiated the crossing when Federal gunboats intervened. With his remaining 900 men Morgan set out on a zigzag course northward through eastern Ohio, seeking to cross into West Virginia or Pennsylvania. Ohioans were terror-stricken at rumours of his approach—it was seldom known exactly where he was—but the raid had become a rout and Morgan surrendered on July 26 near Salineville in Columbiana county; this was the northernmost penetration by a Confederate force during the war. In late November Morgan and six of his officers escaped from the Ohio penitentiary at Columbus and made their way safely to the south.

Another dramatic incident of the war, one that occurred outside Ohio but with Ohioans in the feature roles, was the Andrews raid, or the so-called Great Locomotive Chase, in Georgia in April 1862. In this daring escapade, a score of men from Ohio units infiltrated Confederate territory to Marietta, Ga., stole a train at Big Shanty, and headed for Chattanooga, Tenn., bent upon destroying communication and transportation facilities along the way. Through the sheer determination and perseverance of the train's conductor and a series of remarkably adverse coincidences, the raiders were overtaken after 90 mi. and obliged to abandon the stolen "General." They were captured, imprisoned and subsequently convicted of espionage. The leader, James J. Andrews, and several others were hanged as spies. The survivors either escaped to freedom or were eventually exchanged. Their incredible exploit won for them promotions, an audience with President Lincoln and the first (congressional) medals of honor ever bestowed.

Emerging Political and Industrial Power.—In the postwar decades Ohio emerged as a political and industrial power, besides retaining its standing as a leading agricultural state. It sent to the White House three successive presidents—Grant, Hayes and Garfield—between 1869 and 1881. Hayes, who had been Ohio's first three-term governor, compiled the most creditable record of the three. The election of Benjamin Harrison and William McKinley in the waning years of the 19th century, and of William Howard Taft and Warren G. Harding in 1908 and 1920, respectively, gave Ohio its claim to the title "mother of presidents." Although generally Republican, Ohio voters occasionally have warmly endorsed a Democrat. The most popular of the latter since the Civil War were governors Judson Harmon, James M. Cox, Vic Donahey, George White, Martin L. Davey and Frank J. Lausche. For many years Republicans Robert A. Taft and John W. Bricker enjoyed both state and national prominence.

Industrially, Ohio has excelled in the 19th and 20th centuries in iron and steel, oil, ceramics, rubber, glass, machinery and a host of other products. Industrialization and the urban trend brought to the growing population centres immigrants from foreign lands as well as Ohioans from the farms. The number of farm families was steadily decreasing in the second half of the 20th century and a way of life was fast disappearing.

GOVERNMENT

Administration.—By mid-19th century Ohio's original constitution no longer fulfilled the needs of a rapidly expanding state. As a result, a constitutional convention met and drew up a new instrument of government which became effective in 1851. Twenty-two years later another convention wrote a constitution which was subsequently rejected by the voters. A fourth convention in 1912 decided to retain the existing constitution but submitted 41 amendments for the approval of the electorate. The 33 adopted reflected the Progressive sentiment of that era. Thus, Ohio is still governed under the 1851 constitution modified by numerous amendments.

The executive branch of the state government consists of a governor, lieutenant governor, secretary of state, treasurer, auditor and attorney general. For many years the auditor was the only one of these officials elected to a four-year term, the others being two. This situation was changed, however, by the adoption of a constitutional amendment in 1954 providing for four-year terms for all of these officers starting with the election of 1958. Democrat Michael V. DiSalle of Toledo, the 60th governor, became the first elected for four years when he was inaugurated in Jan. 1959.

The general assembly is composed of two houses, the senate and the house of representatives. Members of the latter still are chosen for only two years, but a constitutional amendment in 1956 extended the terms of senators from two to four years.

The judicial system consists of a seven-man supreme court; nine courts of appeal with three judges each; courts of common pleas; probate, juvenile and municipal courts; and justices of the peace. Judges of the supreme court are chosen by direct popular vote although until 1851 they were elected by the general assembly.

The principal units of local government are the county, township, city and village. The minimum population required for a municipality to become a city is 5,000. Official recognition as a city usually follows the decennial census but may be secured by holding a special census.

Finance.—The costs of operating Ohio's government are paid from the general revenue fund which is derived largely from taxes on cigarettes and alcoholic beverages, a 3% retail sales tax and other forms of indirect taxation. Special undertakings, such as the construction of the multimillion-dollar Ohio turnpike, are financed by bond issues. During and after World War II a vast surplus had accumulated, hailed by some as evidence of wise fiscal management, assailed by others as a "penny-wise, pound-foolish" policy because of alleged negligence of needed improvements. By the close of the 1950s this reserve had been dissipated and, partly because of a reluctance to impose new or increased taxes, the state government faced a $13,000,000 deficit. Primarily by levying higher taxes on cigarettes and gasoline and by restoring the first cent of the sales tax, this deficit was erased by Aug. 1959, and Ohio was once again out of the red. In addition to the expense of conducting the government's business and of maintaining and operating the numerous state institutions and agencies, major expenditures each year include the appropriations for education, highway construction and repair and health and welfare.

POPULATION

Since the residents of Ohio were first tabulated in a United States census in 1800, the state's population has not only increased spectacularly, but it has shifted its concentration and it has undergone significant changes in character and composition. Numbering only 45,365 in 1800, Ohioans ten years later outnumbered the residents of five of the original states. By 1830 Ohio's population had reached nearly 1,000,000, and this figure was doubled in

*Populations are reported as constituted at date of each census. †Known as North Amherst in 1900. ‡Known as Canal Dover prior to 1920. §Known as Washington Court House prior to 1950. ‖Known as Dover prior to 1950. ¶Known as Chicago Junction prior to 1920.
Note. Dash indicates place did not exist during reported census period, or data were not available.

the next 20 years. It passed 3,000,000 in 1880; 4,000,000 in 1900; 5,000,000 before 1920; and 6,000,000 before 1930. It was just short of 7,000,000 in 1940 and 8,000,000 in 1950; and by 1960 it had soared to 9,706,397. With the growth of cities and the exodus from the farms, the population by 1960 was more than 70% urban. As a whole, the state in 1960 had a relatively high population density of about 235.5 persons per square mile, but this figure was multiplied many times in the several large cities, with greater Cleveland's density highest at more than 2,000. This development is in great contrast to the middle of the 19th century when 85% of Ohio's inhabitants lived on farms. Despite the general increase in population after 1950, 18 of Ohio's 88 counties (all but two of them in the south and southeast) not only failed to attract new residents but actually suffered a decline in numbers.

Throughout most of the 19th century, Ohio's original predominantly Anglo-Saxon stock was supplemented by additional immigrants from Great Britain, Ireland and Germany. In 1900 Ohio's foreign-born population consisted of 204,160 Germans and approximately the same number from all other nations combined. The percentage of foreign-born fluctuated little, amounting to between 11% and 14% in the period 1860 to 1920, after which it declined. The sharp increase in eastern European immigrants, however, boosted the number of Hungarians, Poles, Italians, Austrians and Russians nearer to the declining number of Germans. Italians, Czechoslovakians and Yugoslavians continued to increase, especially in manufacturing centres such as Cleveland in which by 1920 one third of the people were foreign-born. This development had a pronounced effect on both political and cultural patterns in such cities.

Similarly, the Negro population has risen steadily. In 1920 the number of Negroes in Ohio (186,187) far exceeded that of the foreign-born from any single country. In the four decades that followed this figure increased by more than four times, while the percentage rose to 8.1% of the total population.

Restrictions on immigration since the 1920s have substantially reduced the foreign-born in Ohio to about 4%, so that approximately nine of every ten Ohioans are native white.

EDUCATION

State School System.—Historically, the principle of public-supported schools was established in Ohio in the 1820s, but it was not fully implemented until many years later. Public elementary schools were widely accepted by the time of the Civil War, preceding by nearly a half century general adoption of the public high school. As the 20th century gained momentum, the long-familiar one-room school gradually disappeared from the Ohio countryside, superseded by consolidated schools serving larger areas. The number of school districts was reduced by 33%, from more than 1,500 to about 1,000 in one decade after World War II. In 1921 school attendance for children between the ages of 6 and 18 was made compulsory. The system is administered by a superintendent of public instruction and a 23-member elected state school board created by the general assembly in 1955.

Colleges and Universities.—There are so many colleges and universities in Ohio (more than 50) that every resident lives within a few miles of at least one institution of higher learning. Of these, six receive financial support from the state. Ohio university at Athens was chartered in 1804, opened its doors five years later, and progressed from academy-type instruction to the standards of a full-fledged college about 1822. Miami university at Oxford followed a similar pattern, undergoing a formative stage from 1809 to 1824 when it achieved collegiate standing. Ohio State university, at Columbus, opened in 1873 as the Ohio Agricultural and Mechanical college, changed its name five years later and went on to become the largest of the group and one of the nation's leading universities. Kent State university at Kent and Bowling Green State university at Bowling Green were normal schools which gained university status in 1935. Central State college, at Wilberforce, after nearly a century as the education and industrial arts section of Wilberforce university (for Negro students) became a separate institution in 1950. Of Ohio's other colleges and universities three are municipally operated, by Akron (founded 1870), Cincinnati (1819) and Toledo (1872), while a considerable number are denominational, among them Baldwin-Wallace college (1845) and Ohio Wesleyan university (1842, Methodist), Xavier university (1831) and John Carroll university (1886, Roman Catholic), Denison university (1831, Baptist), Wittenberg university (1845, Lutheran) and Wilmington college (1863, Quaker). Western Reserve university (1826) at Cleveland is nonsectarian. Oberlin college (1833, nonsectarian) had the distinction of being the first coeducational college in the nation.

HEALTH, WELFARE AND CORRECTIONS

The director of public welfare has under his general control administration of poor relief; aid to dependent children and to the aged, the blind and the disabled; maternal and child health and child welfare services and services for crippled children; state hospitals for the mentally ill, epileptics and tubercular patients, institutions of the feeble-minded; a soldiers' and sailors' home, industrial schools for boys and girls; reformatories for men and women; a prison farm and penal honour camps; and Ohio penitentiary.

Ohio has launched a program to rectify conditions in its state mental hospitals. These institutions house nearly 30,000 inmates besides another 8,000 in state schools for retarded children, a total which is more than triple the number of prisoners in the Ohio penitentiary and the other penal institutions. The annual expenditures for the social and welfare programs and institutions (including general relief, aid for the aged, unemployment compensation and others, in addition to mental and correctional) nearly equal the entire cost of operating the public school system in the state.

THE ECONOMY

Living Conditions.—The steady decline in the number of farms in Ohio has been reflected in the occupational structure in the second half of the 20th century. By the early 1960s only about one out of every 25 wage earners was engaged in farming, unlike a few generations previously when agriculture provided occupations for a majority of the state's citizens. A significant side light on this is that at least half of the farming population worked at other jobs part of the time; a third worked off the farm more than 100 days per year. The number of employees in manufacturing was about ten times as large, outnumbering all other groups. They were followed by the categories of trade, service and professional and transportation, communication, etc. Economic conditions were generally good and wages high. In per capita personal income Ohio ranked among the top 20% of the states.

Agriculture.—Although as individual entities Ohio's farms were disappearing at the rate of about 1% per year in the second half of the 20th century, nearly half the state's land surface was still in crop lands and three fourths of the 88 counties were rural in character. Agricultural production continued high, the chief products being corn, oats, hay, soybeans, tobacco, wheat, rye barley, potatoes, apples, peaches, grapes, pears, sugar beets and maple syrup. Ohio ranked among the leading states in its annual yield of corn, oats and hay, producing, for example, about 8% of the nation's corn. In livestock, cattle were the most valuable as well as the most numerous except for hogs. Sheep, chickens and turkeys also were raised in large numbers.

Industry.—Ohio manufacturing plants and factories, mills and foundries not only provided employment for two fifths of the working force in the 1960s but also supplied the world with diverse and useful products. The principal centres of industry are Cleveland, Akron, Youngstown, Cincinnati, Columbus, Toledo, Lorain Dayton, Canton and the Ohio river cities from East Liverpool down to Marietta. Some cities have been noted primarily for one industry: Akron for rubber; Dayton for cash registers; and East Liverpool for clay products. One fifth of the nation's production of iron and steel came from the mills of Cleveland, Lorain Youngstown, Steubenville, Canton, Bellaire and Ironton. Chemical industries gave new vitality to the river valley in the vicinity of Marietta. Akron enabled Ohio to produce one fourth of the nation's rubber products. Also from Ohio came at least 10% of

all the machinery, transportation equipment, primary metals, fabricated metal products and stone, clay and glass products manufactured in the United States. Other industries produced significant totals of electrical machinery, furniture, petroleum and coal products, chemicals, food products and paper.

Minerals.—Land that at first seemed valuable primarily for farming and timber was found by 1850 to hold beneath its surface vast reserves of salt, copperas (ferrous sulfate, or green vitriol), gypsum, limestone, sandstone and coal, and clay suitable for pottery. By mid-19th century Ohio was fourth among the states in the quantity and value of salt produced. As early as 1840, about 125,000 tons of bituminous coal were being mined annually in eastern and southeastern Ohio. A century later, the state stood among the top six coal producers in the country. Petroleum, natural gas, cement, gravel and building stone all came to be recognized as important natural resources. Ohio still has great deposits of some of these. It is estimated that coal yet unmined may total as much as 50,000,000,000 tons, 5% of the nation's entire reserve. Ohio holds enough rock salt (2,000,000,000,000 tons) to supply the United States, at the present rate of use, for 150,000 years. Two principal petroleum fields have been located in the state, in the northwest and the southeast. About 1900 Ohio was one of the leading oil producers. Of the 200,000 wells drilled since 1860, approximately 14,000 are still active. In roughly the same period, about 175,000 natural gas wells produced more than 2,000,000,000,000 cu.ft., the peak year being 1915 with 79,000,000,000 cu.ft. About 7,000 gas wells are still producing, most of them in the eastern hill country. In the second half of the 20th century Ohio's mineral production has averaged between 12th and 15th in the nation in value, producing about 2% of the total. It has ranked first in the output of lime and fire clay and among the highest in the production of limestone, sandstone, sand and gravel, cement, stone and salt (about 15% of the U.S. total in salt).

Transportation and Communication.—Nature provided the best arteries of transportation in Ohio's early days in the waters of Lake Erie and the Ohio river, as well as in some of the smaller rivers within the state. These secondary streams were important for many years, and the sight of a steamboat far inland was not unusual. The use of the Ohio river declined during several decades of the 20th century, but it has been revitalized and cargo carried on river barges has increased to more than 60,000,000 tons annually.

The canals, discussed earlier, facilitated travel and shipping and contributed greatly to Ohio's economic well-being. Even before the canals' completion, however, early attempts at railroad building were underway, and in 1836 one railroad was completed between Toledo and Adrian, Mich. The middle years of the 19th century brought intense activity in this field, resulting in an intricate network of railroads throughout the state. This hastened the demise of the canals as an important and practical means of travel and transport. A phenomenon of transportation appeared in the early 20th century in the mania for the construction of interurban electric railways. Providing rapid and easy transportation between cities (and sometimes with those in neighbouring states), the interurbans enjoyed a meteoric existence, reaching their zenith in 1917 and then plummeting to obscurity with the advent of the automobile and bus.

Early roads often followed old Indian trails and were quite primitive in character. Dirt was the predominant surface, relieved occasionally by log (or corduroy) roads. The first significant highway-building project was the extension of the National road across Ohio from Wheeling, W.Va., through Zanesville and Columbus to Springfield between 1825 and 1837, and ultimately westward to Indiana and beyond. In the 1950s Ohio focused its attention on the dire need for new modern express highways. The first fruit of this effort was the 241-mi. Ohio turnpike, opened Oct. 1, 1955. Many miles of major expressways have been completed each year, in addition to which several of the larger cities have undertaken construction of systems speeding traffic through or diverting it around congested areas. The state is crisscrossed by nearly 85,000 mi. of highways outside municipalities, of which about 16,000 mi. are state routes, the rest county or township.

Railroads have leveled off at approximately 8,400 mi. while the number of licensed airports has risen to about 100. Lake shipping is busiest at Toledo, Cleveland, Lorain, Ashtabula, Sandusky, Conneaut and Fairport. The completion of the St. Lawrence seaway stimulated commerce on the Great Lakes and brought numerous foreign ships to Ohio ports. The flags of Japan, the Netherlands, Sweden, and other foreign nations are familiar sights on the same waters over which only three centuries ago canoes carried the expedition of La Salle.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures are summarized annually in the *Britannica Book of the Year*, American edition. (J. S. St.)

OHIO COMPANY, in American colonial history, the name of two companies organized in the 18th century for the colonization of the Ohio valley. The first Ohio company was chartered in 1749, partly to aid in securing for the English control of the valley, which was then in dispute between England and France, and partly as a commercial project for trade with the Indians. The company was composed of Virginians, including Thomas Lee and the two brothers of George Washington (Lawrence, who succeeded to the management upon the death of Lee, and Augustine); and of Englishmen, including John Hanbury, a wealthy London merchant. It received a grant of about 200,000 ac. at the forks of the Ohio river, now the site of Pittsburgh, Pa. In 1752 the company had a pathway blazed between the small fortified posts at Will's creek (Cumberland), Md., and at Redstone creek (Brownsville), Pa., which it had established in 1750. The company's uncompleted fort at the forks of the Ohio was captured by the French in 1754. The Ohio company was finally merged in the Walpole company (an organization in which Benjamin Franklin was interested), which in 1772 received from the British government a grant of a large tract lying along the southern bank of the Ohio as far west as the mouth of the Scioto river. The Revolutionary War interrupted its efforts at colonization.

The second company, known as the Ohio Company of Associates, was formed at Boston in 1786 by veterans of the Revolutionary War who hoped to use their depreciated continental certificates at par value for purchase of a large tract of land in the Ohio country. The leaders in the movement were Rufus Putnam, Benjamin Tupper, Samuel Holden Parsons and Manasseh Cutler. Cutler was selected to negotiate with congress and seems to have helped to secure the incorporation in the ordinance of 1787 for the government of the Northwest territory the paragraphs that prohibited slavery and encouraged public education. On Oct. 27, 1787, Cutler and Maj. Winthrop Sargent, who had joined him in the negotiations, signed two contracts with the government. One was for the absolute purchase for the Ohio company, at 66⅔ cents an acre, of 1,500,000 ac. of land lying along the north bank of the Ohio river, from a point near the site of the present town of Marietta, O., to a point nearly opposite the site of the present town of Huntington, W.Va. The other was for an option to buy all the land between the Ohio and the Scioto rivers and the western boundary line of the Ohio company's tract, extending north of the tenth township from the Ohio; according to the records, this tract was preempted by "Manasseh Cutler and Winthrop Sargent for themselves and others"—actually for the Scioto company. On the same day Cutler and Sargent "for themselves and associates" transferred to William Duer, then secretary of the treasury board, and his associates "one equal moiety of the Scioto tract of land mentioned in the second contract," it being provided that both parties were to be equally interested in the sale of the land, and were to share equally any profit or loss. Colonists were sent out by the Ohio company from New England, and Marietta, the first permanent settlement in the present state of Ohio, was founded in April 1788.

The Scioto company failed and left a bad name in history be-

cause of its involvement in the scandalous deception of a group of French colonists, some of whom settled at Gallipolis, O. Nor did the Ohio company prosper. It ultimately obtained about half of the land called for in the contract. However, the company did have a large influence on American history. Cutler and his associates had insisted that the congress make provision for the government of the western territory, and they can thus be credited with having stimulated the adoption of the Northwest ordinance. Moreover, as part of the contract, the Ohio associates were granted two townships of land from the public domain for the establishment of a university. Ohio obtained possession of this land after it became a state; and most of the other public-land states that entered the union after Ohio asked for and got similar or larger grants for state universities.

OHIO RIVER, the principal eastern tributary of the Mississippi river, U.S. It is formed by the confluence of the Allegheny and Monongahela rivers at Pittsburgh, Pa., and flows northwest nearly to the west border of Pennsylvania, south-southwest between Ohio and West Virginia, west by north between Ohio and Kentucky and west-southwest between Indiana and Illinois on the north and Kentucky on the south. The Ohio contributes more water to the Mississippi than any other tributary (basin 203,900 sq.mi.); its volume (231,000 cu.ft. per second) is 3½ times that of the next largest stream, the Missouri. Despite seasonal fluctuations which may reach flood proportions, its fairly uniform flow has supported an important commerce since first settlement began. In all its 975.5 mi., the Ohio has a total fall of only 429 ft., considerably less than some of its tributaries—the Big Miami, for instance, has a fall of 600 ft. in only 160 mi.

The Ohio valley floor is narrow, with an average width of less than ½ mi. between Pittsburgh and Wheeling; from Cincinnati to Louisville it averages a little over 1 mi. and below Louisville it is somewhat greater. There are islands in the river, varying in size from 1 to 4,000 ac. The one major hazard to navigation, the Falls of the Ohio, is at Louisville, where locks take care of a descent of about 24 ft. within a distance of 2½ mi.

Floods.—The Ohio and several of its tributaries have long been known for floods, such as those at Dayton and Johnstown (*qq.v.*). In Jan. 1937, an especially destructive flood set a record for high stages on that part of the river between Point Pleasant, W.Va., and the mouth of the Ohio and on the tributaries entering from the south. Fluctuation in stream level at Cincinnati may be 80 ft., with an average of one flood (varying crest) each 18 months. The Ohio valley lies in the path of prevailing cyclonic storms, annual precipitation averages about 40 in., with rainfall heavier from January to May, when runoff is greatest. On the tributaries of the Ohio, there is no definite flood season.

Tributaries.—Neither the Ohio nor its numerous tributaries has had much water power development, important exceptions being the Tennessee and Cumberland rivers. Nevertheless, several tributaries have been significant in other ways. Within the Ohio system are three major groups of tributaries, each contributing in its own way to the development of the nation's heartland. First of these is the extensive system of headwaters, second the northern tributaries and third the southern tributaries. The first to affect settlement policy were the northern tributaries. The divide between the Great Lakes and Ohio river drainage is not far south of the lakes margin; the tributaries from the north follow roughly parallel courses to the Ohio. The French from the St. Lawrence valley claimed, but were unable to hold, the major valleys between the Great Lakes and Ohio drainage. Since settlement began in 1787, the vitality of these trade routes has grown.

Robert Cavelier, Sieur de La Salle, asserted that he discovered [illegible] Ohio and descended it until his course was obstructed by a fall, said to be the falls at Louisville (*see* Kentucky: *His*[illegible]; Ohio: *History*). In the 1750s its strategic importance [illegible] struggle of the French and the English for possession of the [illegible]terior of the continent became fully recognized. By the tr[illegible] 1763 ending the French and Indian War, the English finally [illegible] undisputed control of the territory along its banks. By the [illegible] of 1783 the entire Ohio country became a part of the United [illegible] and by the famous ordinance of 1787 the north side was open [illegible] settlement. Most of the settlers entered the region by the [illegible] waters of the Ohio and carried much of their market produce [illegible] the Ohio and Mississippi to New Orleans. On any map of [illegible] railroad traffic, the Muskingum, Hocking, Scioto, Miami, W[illegible] and Illinois river valleys localize enormous tonnages; only the Illinois now supports water-borne commerce.

A series of river improvements and basic changes in tow[illegible] and barges have enabled the headwater and Kanawha river[illegible] move an expanding tonnage to the Ohio. For more than a centur[illegible] the federal government has made improvements and it is vir[illegible] all the work of the U.S. army corps of engineers. The U.S. [illegible] guard confines its attention to licensing commercial pilots [illegible] erecting the signs and lights for safety in navigation. The river itself remains a part of the states on its south bank.

Improvements.—The improvement of the Ohio for commerce has lagged behind the improvement in towboats and barges [illegible] carry the ever-growing freight. The channel is 9 ft. de[illegible] there are 46 low-level, movable or roller type dams and their [illegible] each 600 ft. long and 100 ft. wide. A program was initiated [illegible] 1955 to reduce the number to 19, each with 1,200-ft. locks [illegible] such installations, locking time is reduced by more than 33[illegible] traffic costs are reduced 50%.

Use.—Ohio river towboats vary in characteristics depending upon the type of service for which they are designed; [illegible] them used for medium- or long-haul service for coal and genera[illegible] cargo are fairly uniform. A typical towboat is a twin-screw [illegible] h.p. diesel-powered boat 150 ft. long, 35 ft. in the beam [illegible] drawing 7 ft. of water when loaded. Multiple screws are the rule since they allow the application of greater power in shallow [illegible] and also provide the superior steering characteristics essential [illegible] river navigation.

Barges appear on the rivers as the hodge-podge or mixed [illegible] and the more common specialized tow. One towboat will [illegible] 20 barges, 4 barges wide and 5 long, putting them through a [illegible] lock in 2 lockages. Coal and coke make up 55% of the [illegible] tonnage and petroleum and its products 20%; the rest is iron [illegible] steel, chemicals, sand and gravel, sulfur, automobiles and m[illegible]laneous products. There is little grain.

There is no authorized program for the development of hy[illegible] electric power in the Ohio basin proper, but during and [illegible] World War II the Ohio valley has experienced a marked [illegible] in industrialization. Aluminum, chemicals, steel, atomic en[illegible] and electric power plants are important examples of this gr[illegible] To a river already badly polluted by factories, coal mines and [illegible] sewage, these industries aggravate the problem. One impo[illegible] step to alleviate this situation has been the eight-state ratif[illegible] (1948) of the Ohio River Valley Water Sanitation compact pa[illegible] by the U.S. congress in 1940.

OHIO STATE UNIVERSITY, a state-supported, co[illegible]tional institution of higher learning, founded by statute in [illegible] and opened at Columbus, O., in 1873. *See* Ohio: *Education*.

OHM, GEORG SIMON (1787–1854), German phy[illegible] whose most important contribution was Ohm's law of elect[illegible] duction, was born at Erlangen on March 16, 1787, and wa[illegible]

ed at the university there. He became professor of mathematics the Jesuits' college at Cologne in 1817 and at the polytechnic of Nürnberg from 1833 to 1849. In 1849 he was appointed fessor at Munich, where he died on July 7, 1854. His writings were numerous, but, with one important exception, not of the first order. The exception is his pamphlet, published in Berlin in 1827, with the title *Die galvanische Kette mathematisch bearbeitet.* This work, the germs of which had appeared during the two preceding years in the journals of J. Schweigger and J. Poggendorff, greatly influenced the theory and applications of current electricity. (*See* ELECTRICITY: *III. Direct-Current Circuits: Ohm's Law.*) The most important part of the pamphlet is summarized in what is now known as Ohm's law. (*See* INSTRUMENTS, ELECTRICAL MEASURING.) This work was so coldly received that Ohm's feelings were hurt, and he resigned his post at Cologne. At this time his work began to be recognized, he was awarded the Copley medal of the Royal society in 1841 and was made a foreign member of that society in 1842. In addition to a number of papers on mathematical subjects, Ohm wrote a textbook, *Grundzüge der Physik* (1854).

OHRID (OCHRID), a town and *srez* (district) in the Socialist Republic of Macedonia, Yugos. The town (pop. [1961] 16,626), 70 mi. S.W. of Skopje, is situated at the northeast of Lake Ohrid (Ohridsko Jezero) on the old Roman road, the Via Egnatia, that leads to Bitola and Greece. The lake, 2,280 ft. above sea level, with an area of 134 sq.mi. and a maximum depth of 935 ft., lies amid magnificent mountain scenery and is famous for its salmon trout. Its southwestern part is in Albania, and the Black Drin flows out of it to the north. In classical times called Lychnidus, Ohrid derives its present name from the crag (*hrid*) on which the picturesque old town stands. At the summit is the ruined fortress dating chiefly from the period when Ohrid was the capital of the Bulgarian tsar Samuel (980–1014). Among the Byzantine churches in the town are the cathedral of St. Sophia, with 11th-century frescoes, and St. Clement's, built 1295, also with medieval frescoes. The 10th-century monastery of St. Naum, about 16 mi. to the south, close to the Albanian border, crowns a prominent crag above the lake. The inhabitants of Ohrid are mainly occupied in agriculture, fishing and tourism, the town being the chief resort of Macedonia. It is linked by air (summer only), rail and road to Skopje.

St. Clement (d. 916), a disciple of SS. Cyril and Methodius, was the first Slav bishop of Ohrid, which later was the patriarchal see of Bulgaria (*c.* 980–1014), and then an archbishopric (1014–1767). (V. DE.)

OILBIRD (GUACHARO; *Steatornis caripensis*), the sole member of the family Steatornithidae, found in tropical America from Colombia, Venezuela, Trinidad and the Guianas to Brazil and Peru. As big as a crow, the bird has plumage in blended tints of chocolate and gray, barred and penciled with dark-brown or black and spotted in places with white. The oilbird is nocturnal, slumbering by day in deep and dark caverns, in which it nests. Toward evening it awakes and, with a croaking and clattering that has been likened to the sound of castanets, leaves its retreat. The natives kill great numbers of these birds by entering the cave with torches and knocking down the birds with long poles. The birds are then rendered to provide an oil used for cooking and for lighting; hence the common name oilbird. In Trinidad young oilbirds are esteemed as a great delicacy for the table. Studies show that this bird, like the bats, uses echolocation, a "natural sonar," to avoid obstacles while flying in the darkness of caves. This form of navigation is otherwise unknown in birds. (HT. FN.)

OIL CAKE, a feeding stuff of great value, prepared from the residue resulting from the crushing of various oilseeds. For details *see* FEEDS, ANIMAL; COTTONSEED; LINSEED AND LINSEED OIL; COPRA.

OIL CITY, a city of Venango county in northwestern Pennsylvania, U.S., is situated on a bend of the Allegheny river at the mouth of Oil creek, about 75 mi. N. of Pittsburgh, and is divided into three hillside parts by the river and creek. Once the site of a Seneca Indian village, Oil City was founded in 1860, following the drilling of the world's first oil well at Titusville, 16 mi. up Oil creek on Aug. 27, 1859. It was incorporated as a borough in 1862 and as a city in 1871. Along with the Pennsylvania oil industry, it reached its high point between 1860 and 1870 with boats plying the shallow river, taking millions of barrels of oil to Pittsburgh. For many years the city's oil exchange set the world's price of oil. Industries include oil refineries, machine shops and the manufacture of steel drums and tubing, tin cans, bottles, gas engines, pumping machinery, and other oil-well supplies. For comparative population figures *see* table in PENNSYLVANIA: *Population.* (W. A. C.)

OIL PAINTING, TECHNIQUE OF. This article deals with the materials and methods necessary for artistic expression in oil colours, a medium which consists of pigments ground in drying oils.

For discussions of the history of painting, *see* PAINTING; LANDSCAPE PAINTING; PORTRAIT PAINTING; STILL-LIFE PAINTING; MURAL PAINTING; for a discussion of the paints that are used to cover interior or exterior surfaces, *see* PAINT.

The practices of the artist are guided by principles that are based on the accumulated experiences of centuries, aided to some extent by research data from the laboratories of the industrial paint field and those of the museum technologists. The artist is perforce a craftsman. He must be adept in the selection and the specialized use of his materials for more than one reason. He must be able to control his paints so that he can obtain the effects with which he expresses himself. He is profoundly concerned with the permanence of his paintings because a work of art is intended to maintain its original condition as long as is possible. Another of his major concerns is appropriateness: the proper choice or selection of materials, methods and techniques to fulfill his purposes to the best advantage.

Among several accepted, standard methods that have been developed to meet the various requirements for easel painting, oil painting has occupied a pre-eminent position for five centuries. It is universally preferred by artists and their patrons. Other mediums have qualities more appropriate for the expression of particular styles or particular works. Water colour, for instance, has its special working method and its sparkling effects; it lends itself to outdoor sketching because the materials required are simple and portable. Fresco has outstanding mural qualities; tempera, pastel and encaustic have their own special characteristics.

Oil painting, however, combines such a number of advantages that it has retained its outstanding position and has survived through centuries of changing art forms. Most of the paintings in museums, collections and in the everyday world of art are oils; the very word painting implies oil painting. (*See* also ENCAUSTIC PAINTING; FRESCO PAINTING; GOUACHE; PASTEL; TEMPERA; WATER-COLOUR PAINTING.)

TECHNIQUE

The painter has two means of depicting forms in art: line or contour, and tonal masses or colour splotches. Either can dominate his results, or they can be balanced so that they contribute equally. The work of the early tempera painters can be characterized as predominately linear; sometimes this quality is called "dry." Subsequent "juicier" styles of painting have a looser, more spontaneous effect; forms in general are more rotund and flowing and less angular, and tonal masses contribute more to the final effect.

Technically, the artist has two means of applying colour: the

opaque brushstroke, in which the paint effectually hides the ground and depends on the direct reflection of light from its surface for its effects; and the transparent glaze, in which an underpainting or ground contributes to the final effect (*see* GRISAILLE). Each technique is valuable to the painter, but the colour effects of one cannot be duplicated by the other. Opaque painting utilizes white pigment for its whites and pale tints. Painting that employs thin, transparent layers uses a paler underpainting or a brilliant, white reflective ground for its pale tints. Glazing consists of placing thin, transparent colour over a dry underpainting; the effect is somewhat as if coloured cellophane were placed over a surface; many variations and delicate manipulations may be achieved with skilled application.

While each painting method may have superlative attributes, oil painting permits virtually every technique to be successfully applied and even combined in the same work. In general, there is no longer an insistence on the degree of excellence in all of the attributes of a painting that was once demanded; no one expects a single picture to have everything. A superlative degree of technical accomplishment is frequently sacrificed for balance or for an aesthetic emphasis.

There are many reasons for the adoption and continued use of oil paints. The outstanding facility with which fusion of tones or colour is achieved makes it unique among fluid mediums; at the same time, satisfactory linear treatment and crisp effects are easily obtained. Opaque, transparent and translucent painting all lie within its range. It is unsurpassed for textural variation, the manipulation of smooth and rugged, thick and thin, uniform or varied surfaces. Skill in handling can be acquired after a reasonable amount of training and experience. In painting with the water mediums there is a very definite (and frequently erratic) colour change when the paint dries, but with oil paints, the colour the artist puts down on the canvas is the colour of the finished painting. The widest range of styles is possible, from the most simple to the most complex visual effects. Linen canvas is lightweight, it has a desirable texture, and its resilience to brushstrokes appeals to many painters.

All traditional painting mediums are equally permanent when the pictures are given the care normally given to works of art. However, some are fragile (*e.g.*, pastels) and will not stand wear and tear or abuse as well as oil paintings.

MATERIALS

When painted with bad materials oil paintings on aging will suffer defects and blemishes, such as embrittlement, cracking, darkening or yellowing, which can be avoided by observing the rules of correct craftsmanship. Artists' materials have been necessarily of superlative quality, prepared with the utmost striving toward perfection. Although a fine painter is not made by fine materials, the artist is nevertheless severely handicapped if his materials are inadequate. The use of substandard materials for economic reasons has been since ancient times a temptation that artists have had to overcome.

Artists' oil colours are made by mixing dry powder pigments with selected refined linseed oil to a stiff paste consistency and grinding it by strong friction in steel roller mills. The action of the mills is squeezing, not crushing; the object is to disperse the tiny individual pigment particles throughout the oil, rather than to grind them down in size, since for the most part they are sufficiently fine at the start. The consistency of the colour is important; the universal use of tube colours demands that they be uniform within well-established limits. The standard is a smooth, buttery or short paste, not stringy or long or tacky. When a more flowing or mobile quality is required by the artist, a fluid painting medium must be mixed with it. It is important that this be a time-tested, reliable material, for many 18th- and 19th-century paintings have deteriorated because of the use of facile but improper additives.

Traditional practice is based on the use of pure linseed oil colours judiciously thinned with a little turpentine. Technical practices degenerated decidedly during the 18th century; the older traditions of craftsmanship declined with the end of the apprentice system, the new availability of ready-made materials (even though their ingredients were generally of better quality than the older ones) and the new conceptions of artistic purposes. The necessity for improvement became urgent. Sound traditional practices continued, but many painters who desired to emulate the techniques of admired painters of the past, falsely believed that such effects were due to secret recipes that had become lost. The search for the secrets of the old masters led to the adoption of a number of complex painting mediums, mixtures of cooked varnishes, oils and driers, mostly of 18th-century origin taken from the practices of craft or trade painters and decorators. The most prominent of these was a jellylike medium with the strange name of megilp, which conferred the most facile and versatile brushing qualities to oil colour. Others of equal infamy were the asphalts or bitumens and certain unsound pigments, such as Vandyke brown and emerald green.

Unfortunately, cracking, darkening and subsequent ruination was the fate of every area of a painting where these materials were used; they were responsible for much of what conservators call "inherent vice" in a decrepit painting.

Authoritative opinion holds that technical secrets could not have been the sole property of any individual; all of his colleagues, students and helpers would be acquainted with them. The performances of the great masters were largely dependent upon personal attributes that cannot be duplicated by anything that comes out of the varnishmaker's kettle.

PIGMENTS

A pigment is a finely pulverized, insoluble material used to impart its colour effect to another substance. The same materials are used as pigments in all sorts of paints. For artists' use, pigments must conform to rigid requirements. They must possess the highest degree of colour stability under all conditions to which a work of art may be exposed; they must be brilliant, pure, chemically true to type, smooth and fine. Paint pigments do not dissolve in their liquid vehicles but remain suspended in them. Soluble colouring matters are called dyes; these impart their colour effects to materials by staining them or being imbibed by them. Dyes no longer have much use in oil paints; formerly the list of approved pigments contained many lake colours, which were made by fixing dyes on colourless powders. There is a class of white or almost white powders that become colourless or nearly so when mixed with oils, such as chalk, whiting, clay, alumina hydrate and blanc fixe (precipitated barium sulfate). They are called inert pigments, a term that refers to their lack of colouring power, not their chemical stability. Besides being used as extenders or adulterants they also have a few useful purposes in some paints. Formerly artists used many organic pigments of vegetal and animal origin. Now only two organic pigments are approved for permanent painting, alizarin and phthalocyanine, both of synthetic origin. All other approved colours are inorganic or "mineral" colours.

Pigments are either processed from coloured ores, earths or rocks, or they are manufactured by chemical means from raw materials which are not in themselves colouring matters. The approved palette for oil painting consists of:

Reds: Indian red, light red, alizarin crimson, and cadmium light, cadmium medium, cadmium deep and cadmium maroon.

Blues: ultramarine, cobalt, cerulean, manganese and phthalocyanine.

Yellows: cadmium light, cadmium medium, cadmium deep, cadmium orange, ochre, raw sienna, Mars, Naples, cobalt and strontium.

Greens: green earth, viridian, cobalt and chromium oxide.

Browns: raw and burnt umber, burnt sienna and burnt green earth (transparent brown).

Violets: Mars, cobalt and manganese.

Blacks: Mars, ivory and lampblack.

Whites: flake, zinc and titanium.

Unlike some of the other painting materials, there are few difficulties or unsolved problems in regard to pigments. Their history is well documented; it goes far back and it may be followed

"Venus and the Lute Player" by Titian (c. 1490–1576), Venetian; an early example of the use of oil paints in a manner still influenced by the basic principles of tempera

"Madonna and Child" by Giovanni Bellini (c. 1430–1516), Venetian; a work begun in tempera and finished with oil and oleoresinous glazes

Detail from "Hendrickje Stoffels" by Rembrandt van Rijn (1606–69), Dutch; oil

EARLY DEVELOPMENTS IN OIL PAINTING TECHNIQUE

Hand of a nymph, a detail from "Primavera" ("Spring") by Sandro Botticelli (1444–1510), Florentine; tempera

St. Elizabeth, a detail from "Madonna and Child with Saints and a Donor" by Jan van Eyck (c. 1385–1441), Flemish; oil-glazed tempera

OIL PAINTING, TECHNIQUE OF

"Malle Babbe" by Frans Hals (c. 1580–1666), Dutch. An example of Hals' bold, expressive brushwork

"Atalanta and Meleager" by Peter Paul Rubens (1577–1640), Flemish. Solidly painted in oil with careful attention to brilliance of effect and longevity of the work

"Fantasia in Blue" by Hans Hofmann, U.S. An example of the thick impastos and bravura application that characterized much 20th-century painting

"Mary Edwards" by William Hogarth (1697–1764), English. An excellent example of 18th-century English portraiture

FURTHER DEVELOPMENTS IN OIL PAINTING TECHNIQUE

"Self-Portrait" by Thomas Su (1783–1872), U.S. An early Amer-ican experimental work, attempting to emulate the luminous effects of earlier painters

through Greek, Roman, medieval, Renaissance and modern times. The brilliance, permanence and other qualities of pigments have steadily improved; most modern pigments are superior to the older ones. However, artists in every age have had to select a permanent palette and to resist the temptation to use superbrilliant colours with fugitive results.

The written history of pigments includes, besides many brief references in nontechnical writings, some specialized accounts. The *History of Stones* of Theophrastus (*c.* 300 B.C.) tells how cinnabar (native vermilion) is obtained from inaccessible cliffs by shooting arrows to dislodge it, and how roasting red earth alters its shade, a recent discovery at that time. Another classical source is the *Natural History* of Pliny, an encyclopaedic work of the first century, which contains a good deal about pigments. Some of it was written from personal observation but much of it was compiled from various sources including literal translations of some of Theophrastus' chapters. Some of Pliny's technical descriptions are models of accuracy, some are vague and ambiguous, and some are fantastic tales. He describes perfectly the manufacture of white lead (flake white), one of the first synthetic pigments, a process still in use. He admonishes artists to return to the simple palette of the Greeks whose paintings were so superior, and he deplores the Roman tendency to use such novelties as "the slime of India's rivers (indigo) and the corrupt blood of her dragons and elephants." Dragon's blood is a colour obtained from the fruit of an Asiatic tree. Pliny solemnly said it was the blood of the dragon mingled with that of the elephant; whenever they met they engaged in mutually mortal combat, the dragon crushing the elephant in its coils and being crushed in turn as the elephant fell.

The medieval period saw the introduction of vermilion, an improved synthetic counterpart of the ancient cinnabar. The fabulous *azzuro oltremarino* ("blue from beyond the sea") or ultramarine blue was obtained by a lengthy and complex processing of lapis lazuli, a semiprecious stone that came by trade routes from Afghanistan. Lapis ultramarine was the most costly of medieval and Renaissance materials; it was worth well over its weight in gold. For fine work it replaced all the inferior blues; princes and popes doled it out to their painters and there are tales of how lavishly the artists washed their brushes, subsequently to reclaim a pinch of the precious stuff from the wash water for their own use.

Less desirable blues served everyday purposes until the second quarter of the 19th century when a process for the manufacture of ultramarine was developed. Its discovery began with the casual observation of a blue deposit on the soda furnaces in a French chemical plant, and soon thereafter a process was worked out so that this once-treasured rarity became a mass-produced item, the standard blue of commerce and the arts.

In the early years of the 18th century, prussian blue was accidentally discovered when a colour chemist who had been given a wrong chemical for an experiment on a red pigment, poured the unsuccessful batch onto other waste material. Prussian blue is notable as the first completely documented pigment; its date and place of discovery, discoverer and development are all covered in contemporary scientific journals. Prussian blue has several shortcomings, but it is relatively cheap and still survives in industrial use. Despite its poor qualities, artists used it until an accidental blue product was obtained in England in 1935 from the production of alkyd resins. It was soon developed into the useful, permanent phthalocyanine blue, a perfect replacement for Prussian blue in colour and physical characteristics. The painter's palette is enriched from time to time when a pigment with known good qualities, because of its commercial usefulness, becomes economically feasible to produce.

In 1942, after conferences held in New York between artists' colour manufacturers and artists' groups, the national bureau of standards promulgated a voluntary agreement known as Commercial Standard CS 98–42 for Artists' Oil Paints. This set of specifications, based on research done by the then-existing Federal Art project, established standards and provided tests for physical and colour properties, performance and composition. Its official pigment nomenclature alone brought order to a previously confused and chaotic situation that had plagued artists for centuries and had resisted all former proposals for reform. A single pigment used to be known under as many as a half-dozen names, and entirely different pigments went by the same name. Whimsical names were in wide circulation. Since the agreement, artists' tube colours which are guaranteed to meet or exceed the requirements of CS 98–42 are so labeled. (Copies of the Standard may be procured from the superintendent of documents, Washington, D.C.) (*See* also COLOUR.)

Vehicles, Mediums and Thinners.—A vehicle is the liquid component of a prepared paint; it serves to bind the pigment into a durable paint film, to cause it to adhere to the canvas and to allow manipulation of the paint with the painter's brush. A painting medium is a liquid with binding and adhesive properties similar to those of the vehicle. The medium is added to a paint to alter its brushing or manipulative properties. A thinner is a completely volatile liquid whose sole function is to dilute a paint to a more fluid consistency so that it may be spread out more thinly. The thinners used with artists' oil paints are pure gum turpentine and its perfectly acceptable petroleum substitute, mineral spirit.

In order to accelerate drying, a siccative or liquid drier is sometimes used. The one universally approved siccative is cobalt drier, used sparingly in minimum amounts; it replaces the old lead and manganese siccatives.

The vegetable drying oils do not dry like water paints, which lose the bulk of their volume by evaporation. On exposure to air these oils solidify without appreciable loss in volume by chemical changes (oxidation and polymerization); afterward they cannot be reliquified by any means.

Modern fine tube colours are carefully compounded with a minimum oil content; excess oil is one cause of afteryellowing and structurally defective paint films. Furthermore, it will not perform like the blended mediums; hence, straight oil is not used as a painting medium. Poppy, walnut and other drying oils are no longer used in oil colours, except for a small percentage of poppy oil sometimes added by manufacturers in grinding certain pigments to improve consistencies. Mastic and copal varnishes have likewise been outmoded for some time. Megilp, previously mentioned, consists of mastic varnish mixed with oil cooked with lead driers.

The standard technique for best results in regard to permanence has always been to use straight oil colours with the occasional use of a little thinner. But for thin glazes and for special techniques which require a more fluid, mobile consistency and an especially facile handling, mediums are added. There are quite a few on the market, but many artists prefer to mix their own. A good recipe is: one fluid ounce of stand oil, one fluid ounce of damar varnish, five fluid ounces of pure gum turpentine and a small amount (about ten drops) of cobalt drier. Stand oil is a traditional material, a nonyellowing, heat-thickened (polymerized) linseed oil.

The aim in the formulation of such materials is to produce a liquid which will overcome the natural buttery quality of the colour, permit it to be manipulated in the desired manner and leave the final paint film no weaker nor less flexible than the original paint. (*See* OILS, FATS AND WAXES.)

Brushes.—The brush is the item of the artist's equipment in which inferior materials are least likely to produce desired results. Brushmaking is a highly skilled craft that has come through ages of development. In the midst of mechanized production it survives as a handicraft industry. Each brush is made with careful attention.

The top-grade brushes are made in two types: red sable, made from the tail hairs of the kolinsky or red Tartar marten; and bristle, made from a superlative grade of bleached white hog's bristles. Since the early 1940s supplies of the best bristles, which come from eastern European and north Asiatic sources, have been difficult to maintain, although there has been no lowering of workmanship. Very good bristle brushes are not common.

The tips of hairs and bristles are never cut; all trimming and

shaping is done from the other end. Red sable hair has a minute bulge in the middle and tapers to a very sharp point. The hog's bristle is forked or branched at the tip; this is called the flag. Bristle brushes come in numbered sizes in each of four regular shapes: round (pointed), flat, bright (flat shape but shorter and less supple) and oval (flat but bluntly pointed). A poor flat brush will splay like a broom; a good one yields a controllable line and maintains its shape in use because it is skillfully constructed, with incurving bristles set at its edges. Round brushes are generally associated with the earlier painters; flat ones with the more recent past. Red sable brushes are widely used for the smoother, less robust type of brush stroking; they also come in corresponding shapes. Artists also use some supplementary styles, especially for the manipulation of paint after it has been brushed on; for example, the badger-hair blender, which looks something like a shaving brush, is tapped, clean and dry, perpendicularly against the wet surface. A different grade red sable brush, with ox-hair mixed with the sable, is sometimes chosen when very springy, resilient stroking is required. The water-colour brush, a short-handled, round, pointed red sable brush of special construction, is sometimes also useful in small sizes for small, precise work in oil. The painting knife, a finely tempered, thin, limber version of the artist's palette knife, is a convenient tool for applying oil colours in a robust manner. It did not come into wide use until the 19th century, but had a forerunner in the *cestrum* used in encaustic painting (*q.v.*). Artists have learned how to use the painting knife to obtain a number of textural effects, both rough and smooth, keeping the thickness of the paint within safe limits, so that it will survive without cracking. (*See* also BRUSH.)

Painting Grounds.—The surface on which the artist paints and the support or backing for it must be selected with care. The survival of the work, the ease of its execution and the final visual effect are all profoundly involved in this selection. The standard ground for oil painting is a canvas made of pure European linen, of strong, close weave. It is coated with a white oil priming and stretched on a wooden stretcher frame or chassis. Modern stretchers are machine-made so that the tongue-and-groove mitred corners of the strips are interchangeable. The inner corners are provided with slots for wooden wedges, which, when tapped with a hammer, tighten the canvas. For larger sizes, extra-heavy custom-made stretchers of more sturdy construction are available, with crossbars if desired.

Stretchers are beveled slightly to prevent their inner edges from being noticeable through the canvas. In France, the chassis (assembled stretcher), stretched canvases and picture frames are available by number in 57 stock sizes: 19 lengths in three different proportional widths, *figure*, *paysage* and *marine*. For example, number 20F, roughly equivalent to the popular 24 × 30, is 73 × 60 cm., 20P is 73 × 54 and 20M is 73 × 50. In the U.S. and Great Britain it is customary to sell stretcher bars separately and canvas by the roll.

When the artist makes his own canvas he tacks the linen to the stretcher and then sizes it with a weak solution of hide glue to protect it from the oil. It has been known from earliest times that linen in direct contact with oil will decompose on aging. A white lead-in-oil priming is then applied in one or two coats. When, as is more often the case, the canvas is bought ready-made by the roll, the quality of the linen and priming should be carefully examined.

If rigidity and smoothness are preferred to springiness and texture, a wooden panel may be used with an oil priming or a gesso ground. Gesso, a mixture of chalk and glue, is too inflexible for use on cloth. The panel may be a well-made maple or birch plywood or a wallboard with the trade-marked name of Standard Presdwood, which has the advantage of uniformity of structure. Many other supports, textile and metal, have been tried, but few of these are in general use or have wide approval. Cotton canvas, often used by art students, has several shortcomings and is definitely inferior to linen in every requirement.

Varnish.—A coat of picture varnish is usually given to a finished oil painting. This is necessary to protect the painting from atmospheric attacks, from minor abrasions and an injurious accumulation of dirt. It also brings the surface to a uniform lustre, and brings the tonal depth and colour intensity to those originally created by the artist with wet paint. A correctly painted oil painting should be moderately glossy. Formerly, a highly reflectant gloss was considered in good taste, but, except in very low-keyed works, in dark intense paintings or in revarnishing old paintings that have large areas of blackish tones, a glassy shine is no longer widely admired.

When a layer of dust and dirt accumulates on a painting it becomes powerfully adhesive and behaves much as though it were adsorbed into the surface. If the surface is simply oil paint, the removal of this embedded grime presents a serious problem and its effect is sometimes ruinous. If the painting is protected by a coating of picture varnish, cleaning by the removal of part or all of the varnish film is a relatively safe and easy procedure. (*See* PAINTINGS, CONSERVATION OF.)

Some 20th-century painters, especially those who do not favour the deep, intense type of colouring, have wanted a mat or lustreless finish in oil paintings, but this seems unobtainable by any means if the longevity of the painting is to be considered. It is well known in the industrial paint and enamel field that lustreless finishes are obtained only at a definite sacrifice of durability.

An acceptable, mat varnish for permanent easel painting has not been invented, although there are some that are adequate for decorative work or other purposes for which permanence is a secondary consideration. Oil painting in the past was never intended to be other than glossy; admiration for this quality was one of the attributes which contributed to its adoption. Other types of painting, water colour, gouache, tempera, casein, fresco and pastel, have dead mat or semimat finishes. The aqueous paints in comparison to oil have powerful, gluelike binders; their chief ingredient (water) evaporates, leaving no surplus vehicle to surround or encase the pigment in a transparent pellicule or film, as oil paint does. They therefore have a different optical effect on the pigments. The gloss of an oil painting is a natural function of the medium.

The two approved varnishes which come nearest to fulfilling most of the ideal requirements for a picture varnish are damar (a solution of a pale East Indian resin in turpentine) and acrylic (a solution of a water-white synthetic resin). Two outmoded picture varnishes still in circulation are mastic (made from a resin from the Mediterranean countries) and copal (a cooked linseed-oil varnish containing a very hard African resin). Both of the latter are relatively dark in colour and turn brown or brownish-yellow upon aging. Copal has the additional disadvantages of cracking with age and of becoming difficult to remove when it needs replacement. Besides picture varnish the artist may use a very dilute resin solution known as retouch varnish. This is not a finish; it is employed as an extremely weak or attenuated covering to bring out the natural wet gloss and colour effect when work is resumed on a painting that has dried and become sunken-in. It is intended to be used for this one purpose and is not supposed to form an appreciable film or layer, or to give permanent finish or protection.

Paintings are varnished as soon as they are completely and thoroughly dry. When thick, glassy coats of mastic or copal were in vogue, artists waited for months before varnishing to avoid any physical injury to the soft paint layers by the contraction of the varnish. (*See* also VARNISH.)

HISTORY

The practice of easel painting with oil colours stems directly from 15th-century tempera painting techniques; its development can be followed without interruption. Oils, varnishes and oil colours were known and used for several decorative and protective purposes long before their adoption by artists. Drying oils are described in manuscripts by ancient and medieval writers; oil as a painting medium is mentioned in the treatise of Theophilus (11th century).

Well known to all students of early painting methods is the

book of Cennino Cennini (*see* TEMPERA), a 14th-century painter whose practices descend directly from Giotto's studio; there are several references to the preparation of oil painting materials and the methods used for various purposes. One chapter (no. 89) is titled "How to work in oil on a wall, on a panel, on iron or wherever you please." Numerous other references are found in old expense accounts, for instance: "The King to his treasurer and chamberlains. Pay from our treasury to Odo the goldsmith and Edward his son one hundred and seventeen shillings and tenpence for oil, varnish and colours bought, and for pictures executed in the Queen's Chamber at Westminster . . . May 25th to June 11, 1239."

Basic improvements in the refinement of linseed oil and the availability of volatile solvents or thinners for varnishes and oil paints after 1400 coincided with a need for some other medium than pure egg-yolk tempera to meet the changing requirements of the Renaissance. The new demands were particularly exemplified in Venetian painting. Painting developed away from the dry, linear effects that had prevailed; the new materials allowed new techniques of handling colour, tonal masses and depth of colour. At first oil paints and varnishes were used to glaze tempera panels, painted with their traditional linear draftsmanship. The work of Antonello da Messina, Domenico Veneziano, and the technically brilliant, jewellike portraits of the 15th-century Flemish painters were done this way. Among the earliest of these oil-glazed tempera paintings were the works of Jan van Eyck of Bruges (1385?–1441) and his brother Hubert. In 1550 Giorgio Vasari published his *Lives of the Painters*, in which he credited "Giovanni da Bruggia" with the "invention" of oil painting. This statement made such a strong impression, on Flemish and Dutch historians in particular, that the belief that the Van Eycks were the first artists to discover that one could make paint with linseed oil, persisted for centuries. Scholars since 1781 have shown that although Jan van Eyck, one of the great masters of all time, was important in the history of painting, oil painting was neither his invention nor that of any individual, but was the result of a long, gradual development. In the lives of the painters who lived nearer his own day and in his technical chapters "The Three Arts of Design," Vasari records information of great value; his direct, factual statements about 16th-century technical practices refute those who hold that there are lost secrets of the old masters.

In the 16th century oil colour emerged as the basic painting material in Venice. Artists had to learn gradually how to assure themselves of permanent results and how to develop fluent control. Since their traditions developed from tempera painting, they first relied on glazes and on carefully and deliberately planned cartoons and underpaintings, retaining many of the cardinal principles of the older technique. This type of painting utilized the effects of the drawing and underpainting which were never entirely obscured.

The emphasis on the oil glazes increased until the overpaintings gradually became more solid and direct, and the dry or linear character gave way to a more balanced combination of line and tonal effects, the latter obtained by use of directly applied, opaque colour areas or splotches. This progression can be followed in the lifetime of one artist, Giovanni Bellini (*c.* 1430–1516), who worked at first in pure egg tempera, then passed through an intermediate stage in which he must have used some oily ingredient, then covered his works with thin oily glazes and finally employed heavier oil coatings.

The work of Titian (*c.* 1487-90–1576) and Tintoretto (1518–94) carried on the development and during the 16th and 17th centuries most of the technical possibilities of oil painting were explored, at least in principle. Later investigations that were made into specific recipes for the oily mediums used by the masters of this period, brought about very involved, confused and contradictory interpretations, discussions and arguments, in the 18th and 19th centuries.

In the early years of oil painting, so many mixtures of oils and varnishes were tried and recorded in manuscripts, so many were subsequently discarded when their lack of permanence was established and so many recipes designed for trade or decorative uses later passed as artists' mediums that it is doubtful whether anyone can make any really authoritative statements or generalizations on exactly who used what and when.

By the end of the 16th century, artists had become proficient in the exploitation of the basic characteristics of oil painting; the means of expressing personal techniques, while ensuring longevity, had been learned. Linen canvas, after a long period of development, replaced wooden panels as the most logical and popular support. Cennini discusses the use of colours on linen and hempen cloth on wooden stretchers, and on banners, standards and trappings. It was adopted for easel paintings, because oil paint has sufficient elasticity to give permanent results when properly applied upon it.

Velázquez (1599–1660), who can be said to represent the culmination of the Venetian tradition, is usually cited as the first master whose technique can be copied by simple, direct oil painting, as it was later practised. His direct uncomplicated use of colour and his bold, bravura brushstrokes have frequently been emulated, especially in portraiture. Peter Paul Rubens (1577–1640), who represents the culmination of the Flemish school, was a prodigious painter of the very highest personal attainments. His studio has been called a picture factory because of his output and because he employed so many colleagues and students as assistants. He charged a higher fee for paintings entirely executed by his own hand, but boasted that no painting left his possession without being gone over by himself, at least in its salient points. Much is known of his manner of working and his basic techniques, some of it from his own writings. The technical significance of Rubens as an influence on later painters is the manner in which he loaded or piled up his whites and pale colours, opaquely, in juxtaposition to thin, transparent darks and shadows. He is also admired for another and sketchier style of handling. Over a brilliant, reflective white ground, he laid a cool, gray transparent film of paint (*imprimatura*); on this he painted a fully modeled monochromatic underpainting in a thin, translucent brown. Brilliant colours were then stroked in with a light, sure touch. Painters of this period sometimes employed coloured grounds, particularly in earth reds, but Rubens' combination of the reflective white and a transparent veil of colour utilized the technical advantages of both.

A third great master of oil-painting technique of this period is Rembrandt (1606–69) who can be considered to represent the culmination of the Dutch school. His technical effects had perhaps the most profound influence of all on later painters, particularly his brushwork, his handling of paint textures and surfaces, and his paint quality and visual effects. A single brushstroke sometimes reveals an effective depiction of rotundity of form and a textural depth combining the rough and the smooth and the thick and the thin. The system of loaded whites and transparent darks, so pronounced in Rubens, is enriched by further touches of broken opaque strokes, which do not obscure the underlying colours, in addition to glazed effects and blendings. Rembrandt left no record of his materials, but he is presumed to have used much stand oil, a heat-processed or polymerized linseed oil for which the Dutch have long been famous.

Other basic influences on the techniques of later easel painting are the smooth, thinly painted, deliberately planned, tighter styles of painting. These were never discarded; they have continued to have their followers in every generation. Bold, crisp brushstrokes and any areas or spots raised considerably above the level of surrounding colour are called impasto. A great many admired works were executed with smooth gradations and blends of tones to achieve rotund forms and subtle colour variation. The paintings of Jan Vermeer (1632–75) may be cited as examples. His direct painting is combined with restrained and subtle blends without diminishing the forcefulness of the work.

An interesting effect seen in some old paintings is called *pentimento* ("repentance"). Because of changes in the refractive index of linseed-oil films after aging, it is possible for thinly painted layers to become transparent, revealing forms that had been covered over.

There are numerous examples in galleries, in which the artist had used thin overpaintings of paler colour to obliterate dark forms that in time became visible in a ghostly manner. Examples are found among the thinly painted Dutch panels of the 17th century, especially where the checkerboard marble floors they were so fond of depicting have come through thinly overpainted figures and objects. Painters have learned to avoid *pentimenti* by scraping away dark markings before overpainting with paler colours or by making the overpainting sufficiently opaque to preclude this occurrence.

Painting in the 20th century has created many technical problems. In addition to traditional art forms, many new schools have arisen. The technical requirements of some of these are well served by the materials and technical means of the past; others cannot be realized by the use of paints that were developed specifically for the craftsmanship and painterly qualities associated with traditional techniques.

The demands of French Impressionist painting had coincided with improvements in paint-grinding machinery that permitted the manufacture of artists' oil colours to a more buttery or less mobile consistency. Some abstract painters, and to some extent contemporary painters in traditional styles, have expressed a need for an entirely different plastic flow or viscosity than can be had with oil paint and its conventional additives. Some require a greater range of thick and thin application and a more rapid speed of dry. Some artists have used the traditional materials in unorthodox ways, such as mixing coarsely grained materials with their colours to create new textures; some have used oil paints in enormously heavier thickness than has been considered safe. Abandoned techniques have been revived to cope with such problems and experimental paints based on synthetic resins have been tried. *See* also PAINTINGS, CONSERVATION OF.

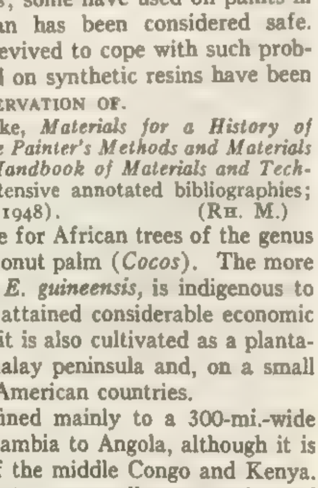
OIL PALM, the common name for African trees of the genus *Elaeis*, botanically allied to the coconut palm (*Cocos*). The more widely known of the two species, *E. guineensis*, is indigenous to tropical west Africa, where it has attained considerable economic importance as a source of oil, but it is also cultivated as a plantation crop in Indonesia and the Malay peninsula and, on a small scale, in some Central and South American countries.

The oil palm in Africa is confined mainly to a 300-mi.-wide region along the coast from the Gambia to Angola, although it is also found in the forest regions of the middle Congo and Kenya. It is a light-demanding species but grows well on a variety of deep, well-drained, neutral or alkaline soils. In maturity it may attain a height of 100 ft. but normally has a stem of no more than 30 ft., which bears at the summit an irregular crown of feathery leaves, each of from 10 to 15 ft. in length and pinnately divided into 50 or more lance-shaped leaflets. The numerous flowers are crowded on a short spadix and develop into a large ovate fruit cluster that may contain more than 1,000 drupes, varying in colour from a deep yellow to a dark red-brown. Mature palms bear from two to six bunches of fruit, each normally weighing between 10 and 35 lb., approximately one-third of which consists of stems or bracts.



PAUL POPPER LTD.

FRUITING OIL PALM (ELAEIS GUINEENSIS)

The individual fruit is 1–2 in. long and ¾–1 in. in diameter, its weight varying from 3 to 25 g. The fibrous pericarp, or outer fleshy portion of the fruit, yields between 30% and 70% of its weight as palm oil, while the kernels in the endocarp are approximately 50% by weight of palm kernel oil. Palm oil, deep yellow to red-brown and butterlike in consistency, is used chiefly in making soaps, candles and lubricating greases and in processing tinplate and coating iron plates; palm kernel oil, of a different chemical constitution, is a thick, light yellowish oil, used primarily in the manufacture of edible products such as margarine, chocolate confections and pharmaceuticals. The kernel cake residue is a good cattle feed and fertilizer.

The weight ratio of pericarp to kernels varies considerably, from the thick-shelled variety *macrocarpa*, whose pericarp composes about 50% of the weight of the fruit, to *pisifera*, a form with no pericarp at all. The variety *dura*, with a pericarp about 30% of the weight of the fruit, is the one commonest in western Africa; in Malaya selection has produced *dura* trees that yield more oil than those in Africa. Research into the improvement of *E. guineensis* strains has been concentrated mainly upon the thick pericarp varieties and, in particular, upon dwarf varieties which facilitate harvesting of the fruit.

OIL PLANTS. Oil has been obtained from plants since the beginnings of recorded history. Its first uses were probably for illumination, anointing and cooking. The discovery that linseed oil would mix with pigments to make an excellent artist's paint undoubtedly encouraged the tremendous increase in painting during the Renaissance. Castor oil was used before the petroleum era as a lubricant for wheels of carts and wagons.

Margarine as a butter substitute was developed in France in the 19th century. By the second half of the 20th century annual world production of vegetable oils was more than 32,000,000,000 lb. (in the U.S., more than 1,000,000,000 lb. being used for margarine alone).

This article identifies the sources of oil in plants and the important oil plants and plants from which oil is extracted as a by-product, and discusses uses of oils and oil plant by-products, improvements in oil plants and trends in production.

Additional information on uses will be found in separate articles on products, as MARGARINE; PAINT, etc., and by-products, as COTTONSEED; FEEDS, ANIMAL; etc. *See* also TROPICAL AGRICULTURE and articles on individual trees and plants, as OIL PALM; SOYBEAN, etc.

Sources of Oil in Plants.—All living plant cells contain some oil. This is true not only of the higher plants but also such primitive plants as bacteria, algae and fungi. When oil is present in large amounts in tissue it usually functions as a food reserve. Oil will produce about two and one-half times more calories than the same weight of carbohydrate.

Oil in large amounts is found usually in the seeds of plants, and occasionally in the fleshy part of the fruit, as in the olive and oil palm. Seeds may contain from 1% to over 60% oil, most species having rather large amounts. The oil functions as a reserve of high-energy food for use by the germinating seed (starch has a similar function in starch-storing species such as wheat and corn). In seeds large amounts of oil are associated with large amounts of protein, which makes oilseeds an important source of protein for livestock feeds. (*See* also NUT.)

Roots are not normally a site of oil storage, the oil content rarely going above 10% on a dry-weight basis. One exception is the sedge, *Cyperus esculentus*, native to southern Europe and Africa. This plant produces small tubers or underground stems which, when dry, may contain 20% to 36% oil. This oil is similar to rice-bran oil or olive oil. Other vegetative (as opposed to reproductive) parts of plants usually have less than 5% oil on a dry-weight basis. The vegetative parts of some plants, however are important sources of volatile or aromatic oils used in perfumes or flavours. (*See* ESSENTIAL OIL.)

Some fungi produce large numbers of fat globules, the amount reaching as high as 50% on a dry-weight basis. During World Wars I and II, when fats were scarce in many countries, there was considerable interest in fungi as a source of oil. Research is

Germany indicated that a species of *Fusarium* would produce an oil similar to olive and peanut oils.

Important Oil Plants.—Many plant families have contributed species, ranging in size from the palms to small herbaceous types such as flax, that have been used as a source of oil. Oil crops include plants over a wide range of domestication. At one extreme are babassu, oiticica and the species that yield mowrah and shea butter; these grow only in the wild state. The oil palm and castor bean grow wild and are also cultivated. The coconut, many trees such as tung and olive and all herbs utilized for their oil are cultivated. In fact very few of the herbs in their present form would survive in the wild.

Most of the more important oil crops are found in tropical and semitropical areas. Actually one-half to one-third of the vegetable oils for export have come from the tropical areas of west and central Africa and the area of Indonesia, the Philippine Islands and Malaya. In cool temperate areas the oil crops are flax, rape, mustards and sunflower. These crops of cool temperate areas are often used in hot and semitropical areas also, where they may be grown during the cooler part of the year. For example, rape is grown in Canada and northern Europe, and is at the same time one of the important oil crops of India.

The oil palm produces the highest oil yields of any crop, 2,880 lb. of oil per year per acre having been obtained in Sumatra (by way of contrast the average yield of linseed oil and soybean oil in the United States is less than 300 lb. per acre). Heavy investments, however, are necessary to establish palm plantations, and they do not bear for at least four or five years after planting. They also require much hand labour. Castor beans under good cultural conditions have given up to 2,000 lb. of oil per acre.

The production of other oil crops from trees, such as tung and olive, present some of the same advantages and disadvantages as the palms. Tung and olive trees are slow to get established, but once in production they require little upkeep. They are not readily adapted to mechanical harvesting, though some equipment is available to remove olives from the trees. Castor beans may be grown as a perennial tree in the tropics but as an annual in temperate areas.

Most of the herbs are adapted to production with mechanical equipment. Perilla, sesame, rape and the mustards tend to shatter their seed at harvest time, and have not been harvested too successfully with combine harvesters. For some, such as the castor bean, specially designed harvesters have been developed.

In recent years there has been increased interest, particularly in the United States, in oils for edible purposes that are high in linoleic acid, a polyunsaturated fatty acid. This stimulated a corresponding interest in safflower oil with a high ratio of linoleic acid to saturated fatty acids (about 9:1) and corn oil with a ratio of 5:1. Safflower was a new crop to North American agriculture and had become established because of the superior qualities of its oil in paints and varnishes.

Oils as By-products.—Several of the oils are by-products. The most important of these is cottonseed oil, obtained by processing cottonseed (*q.v.*). Soybean oil might also be considered a by-product of the production of the seed for the protein meal; certainly the crop usually could not be grown profitably for its oil alone. Mustards are grown primarily as a condiment; the oil is a by-product. Corn oil is obtained as a by-product of industries using corn for its starch, and rice oil is recovered from the bran after its removal from the seed in the production of polished rice. Oil is often taken from the seeds of grapes in the wine industry and from the seeds of fruits such as peaches, apricots and cherries in the canning industry. Even weed seeds removed from cereal grain in large terminal elevators may be processed for the oil that some of them contain—the seeds of wild radish and wild mustard are examples.

Tall oil, a by-product of the manufacture of kraft (sulfate) process paper from wood pulp, has been used in paints, linoleum, soaps and emulsifiers. The yield of oil totals about 70 lb. for every ton of pulp produced, but the amount is influenced by the species of pine and the method of pulp manufacture.

Uses.—Vegetable oils are used principally for food, for soap and detergents, for paint and related products and for a variety of industrial items. The iodine value of the oil is usually a measure of its utilization; a low iodine value is characteristic of oils used for food and soap, and a high iodine value of oil that is employed in paint and industrial products. Oils with intermediate iodine values, such as soybean and sunflower oil, are more flexible in their use. (*See* also OILS, FATS AND WAXES.)

Among food products that contain large amounts of vegetable oil are shortening, margarines and salad and cooking oils. The availability and price of oils will determine which is used; soybean oil and cottonseed oil are used extensively in the United States, sunflower oil in the U.S.S.R. and Argentina and coconut oil in many countries. Even linseed oil may be used as a food oil if supplies of the more common food oils are scarce. With the increased use of coal-tar- or petroleum-derived detergents, the volume of vegetable oil used in soaps decreased in the late 1950s. Large amounts of detergents, however, were made from coconut oil. Linseed oil has long been an important ingredient of paint and varnish (*qq.v.*), though its tendency to yellow with age has discouraged its use in light-coloured paints and clear varnishes. Soybean oil, tung oil and dehydrated castor oil are used in many paint products. Rubber-base paints are easier to apply in many situations and have tended to displace in part those made from oil. However, recently developed paints with a vegetable oil base are convenient to handle, in that brushes may be cleaned in water. Other products made from vegetable-oil products are linoleum, oil cloth, printing inks and plastics. Sebacic acid, important in the manufacture of nylon, is made from castor oil. Castor oil when sulfonated is used in the textile-dyeing industry. Palm oil is extensively used in tin-plating.

Technology has expanded the utilization of oil crops. Hydrogenation, the addition of hydrogen ions to saturate the carbon chain structure of oils, permitted the hardening of liquid oils into solid fats. Dehydration of castor oil enabled its utilization in the making of paint products. Fractionation permitted the division of oils into two or more components, each useful for specific purposes. But while technology extended the utilization of vegetable oils, it also developed competing nonvegetable products.

Some vegetable oils are interchangeable, and in the second half of the 20th century a rapidly expanding technology was making them even more so. Cottonseed oil may be substituted for coconut oil or soybean oil in many products, and safflower oil may be substituted for linseed oil. Dehydrated castor oil may function in place of tung oil in some paint mixtures. The effect of similarities in oils and of technological developments is to keep the prices of oils more or less the same, unless one is needed for a specific product.

In addition to their use as sources of oil, most of the oil crops have other commercial uses. Peanuts may be grown for their edible oil or they may be roasted and used as nuts or made into peanut butter. (*See* PEANUT.) Sunflower seeds often serve for similar purposes. The coconut is a staple food in many tropical areas. Soybeans may be grown as a vegetable, as a hay or as a soil-improvement crop. Flaxseed may be a by-product of the culture of flax for its fibre; the flax (linseed) varieties grown for oil are too short to give a satisfactory fibre for linen, but they are used in paper manufacture. The dried and highly coloured blossoms of safflower are used in some areas as a source of dye to colour cloth and foods. Sesame and poppy seeds are used for decoration and flavour in bakery products.

By-products.—The most important by-product of oilseeds is the residual meal or cake remaining after the extraction of the oil. Indeed, the value of the meal frequently determines the agricultural and commercial success of an oil crop. Usually the meal is used as a protein concentrate in feeding livestock and poultry. As a consequence the value of the meal is frequently measured by the protein content and quality. Where the residual meal is poisonous to animals, as it is with castor beans and tung nuts, it can be used only as an organic fertilizer. Considerable amounts of oilseed protein are also used for industrial purposes. Soybean meal is used in plywood adhesives, and an increasing amount of protein is utilized in the manufacture of synthetic fibres.

Improvements in Oil Plants.—Plant breeders are aiding the advance of some oil crops toward domestication. Castor beans, essentially a wild plant of tropical and semitropical areas, after 1940 rapidly moved toward the status of a cultivated crop; varieties that have nonshattering capsules, that are uniform for plant and seed size and that are much shorter than the wild types were developed. Improved sesame varieties that do not shatter also became available.

The area of adaptation of oil crops was in the meantime being extended. In the United States, for example, the area of soybean production increased in 20 years from about 1,500,000 ac. in 1924 to more than 27,000,000 ac. by the 1960s, mostly because adapted varieties were developed for many areas. The development of safflower varieties with high oil content and high yield permitted the establishment of this crop in the United States. Earlier maturity was developed in several oil crops, which promised to extend the area of production—a particularly important development for countries having a cool temperate climate.

Among the established oil crops seed yield and oil content were being increased to permit higher yields of oil per unit area. Where diseases became a problem, which was inevitable when large areas were grown to a single crop, efforts were required to develop resistant varieties. More attention was given to the fatty acid components in the oil of different varieties, since markets were becoming more specific in their requirements.

Trends in Production.—Production of vegetable oils increased about 50% between 1920 and 1950, much of this increase following the introduction of the plantation system in the Netherlands East Indies and the use of better varieties of oil palm.

There is a tendency for nations to try to become self-sufficient in their supply of vegetable oils. This tendency encouraged the increase in acreages of rape, sunflower and soybeans in Canada after World War II. Sunflowers became an important oil crop in Argentina and Chile. After 1930 the United States became increasingly self-sufficient in its supply of soybean and linseed oils. As tropical countries develop higher standards of living the supply of oil for export will decrease unless the acreages of oil crops are extended. It appeared likely, however, that the tropics would remain an important source of oils for export; yields of oil were high, and there were large areas of land in the tropics that could still be developed agriculturally.

OIL REFINING: *see* PETROLEUM.

OIL RESERVES SCANDAL (U.S.). The oil reserve scandal of the early 1920s, usually referred to as the "Teapot Dome" scandal, enmeshed certain high officials in the administration of Pres. Warren G. Harding in charges of corruption and misappropriation involving the nation's oil reserves. Pursuant to a 1910 act of congress, certain oil-bearing federal lands had been set aside and designated by the U.S. government as naval oil reserves. Reserve no. 1 embraced 38,000 ac. of public and private lands in Elk Hills, Calif. (1912); reserve no. 2 contained 30,000 ac. of public and private lands in the Buena Vista Hills, Calif. (1912); and reserve no. 3, Teapot Dome, Wyo., contained 9,321 ac. of public lands (1915). In an act of June 4, 1920, congress directed the secretary of the navy to conserve the properties and lease them if necessary for protection against drainage by adjoining private lands. The policy reflected by the acts and reserves was to "maintain a great naval petroleum reserve in the ground."

Soon after his inauguration, President Harding on March 5, 1921, appointed Albert B. Fall as secretary of the interior and Edwin Denby as secretary of the navy. On May 31, 1921, at the instance of Secretary Fall, President Harding signed an executive order transferring the administration of the naval petroleum reserves from the secretary of the navy to Fall as secretary of the interior. Secretary Fall thereafter entered secret negotiations with H. F. Sinclair of the Mammoth Oil company; on April 7, 1922 Fall issued, without competitive bidding, a lease covering all of the lands in reserve no. 3 (Teapot Dome) to the company, granting it the exclusive right to take and dispose of oil and gas from the reserve. No imminent danger existed that the oil would be lost by drainage. Secretary Fall in 1921 and 1922 also secretly negotiated contracts and leases with E. L. Doheny covering lands in reserves no. 1 and 2, executed in 1922 with the Pan American Petroleum and Transport company and the Pan American Petroleum company, both controlled by Doheny. All of these leases and contracts were also signed by Secretary of the Navy Denby, but the courts found that Denby was passive throughout and had signed under misapprehension and without full knowledge of their contents.

The leases and contracts came under investigation by committees of the U.S. senate, where it was disclosed that shortly after the signing of the Teapot Dome lease, Fall and members of his family received from an unknown source more than $200,000 in Liberty bonds under circumstances indicating that the bonds came from a company organized by Sinclair and others receiving benefit from the lease. Also, it appeared that prior to the execution of the Pan American contracts and leases, Doheny, at Fall's request, sent $100,000 in currency to Fall as a "loan" which had not been repaid.

On Feb. 8, 1924, a joint resolution passed by congress stated that it appeared from the evidence that the leases and contracts negotiated by Fall with Sinclair and Doheny were executed under circumstances indicating fraud and corruption, without authority on the part of the officers purporting to act for the United States and in defiance of the settled policy to maintain in the ground a great reserve supply of oil adequate to the needs of the navy. It declared the contracts and leases to be against the public interest and directed the president to institute suits to cancel them and to prosecute any civil or criminal actions that might be warranted.

Cancellation of the leases and contracts was later confirmed in separate cases by the U.S. supreme court. The court ruled that the leases and agreements were made fraudulently and that the executive order of May 31, 1921, transferring the administration of the reserves to the secretary of the interior was illegal. In criminal actions Doheny and Sinclair were acquitted of charges of bribery and criminal conspiracy, but Fall was convicted of accepting a bribe in connection with the Elk Hills lease and served a prison term.

(N. E.)

OILS, FATS AND WAXES, as they will be discussed in this article, occur in plants and animals as esters of alcohols and straight-chain carboxylic acids containing even numbers of 12 or more carbon atoms. They are insoluble in water and are oily or greasy to the touch. Fats and oils are esters (glycerides) of glycerol, a three-carbon, straight-chain alcohol with three hydroxyl groups. Waxes are esters of alcohols other than glycerol which contain, in most cases, only one hydroxyl group but occasionally two such groups. The wax alcohols are either (1) sterols such as cholesterol; or (2) straight-chain alcohols with even numbers of carbon atoms above 14, such as cetyl alcohol, $CH_3(CH_2)_{14}CH_2OH$. The carboxylic acids that occur in plant and animal oils, fats or waxes are called fatty acids.

The term oils is used in a generic sense to describe all substances that are greasy or oily fluids at ordinary temperatures. The term also can refer (1) to the individual fatty or fixed (*i.e.*, nonvolatile) oils such as olive or soybean oils; (2) to the hydrocarbon or mineral oils and derivatives such as petroleum, shale oils, oils from the low-temperature distillation of coal, fuel oils and lubricating oils; and (3) to the odoriferous volatile oils usually called essential oils, such as oil of cloves. The mineral or hydrocarbon oils (*see* COAL TAR; PARAFFIN HYDROCARBONS; PETROLEUM) and the volatile oils (*see* ESSENTIAL OIL) do not come within the scope of this article.

The information in the present article is supplemented by presentations in many other articles. For example, the article OIL PLANTS discusses the source and use of vegetable oils and many of their by-products. Separate articles will be found on many of

the individual oils, fats and waxes or their sources; *e.g.*, BEESWAX; BUTTERFAT; CASTOR OIL; COD-LIVER OIL; COPRA; COTTONSEED; LARD; LINSEED AND LINSEED OIL; OLIVE OIL; PEANUT; SAFFLOWER; SOYBEAN. Additional information on the chemistry of oils, fats and waxes appears in such articles as CARBOXYLIC ACIDS: *Specific Carboxylic Acids;* ESTERS; GLYCEROL; OLEIC ACID; PALMITIC ACID; STEARIC ACID.

Classification.—The substances considered here, as noted above, may be divided into two large classes: (1) oils and fats; and (2) waxes. The distinction between the two classes is based on their chemical composition. The oils and fats consist primarily of glycerides that are esters formed by the union of three molecules of fatty acids with one molecule of glycerol.

$$\begin{array}{l} CH_2OH \\ | \\ CHOH \\ | \\ CH_2OH \\ \text{Glycerol} \end{array} + \begin{array}{c} 3C_{15}H_{31}COOH \\ \\ \text{Palmitic acid} \end{array} \rightarrow \begin{array}{l} CH_2OCOC_{15}H_{31} \\ | \\ CHOCOC_{15}H_{31} \\ | \\ CH_2OCOC_{15}H_{31} \\ \text{Tripalmitin} \end{array}$$

Formation of a simple glyceride

Oils are usually liquid at ordinary temperatures, such as 25° C. (77° F.); fats are solid at this temperature. However, there is no basis for chemical distinction between the two. The difference is only a physical one that can be removed by changing the environment.

Use of the word fat to include both fats and oils is becoming common, especially among chemists. Thus, both soybean oil and tallow would be considered fats. This terminology avoids confusion with nonfatty oils. No sharp distinction can be made between fats and oils, because at sufficiently low temperatures all oils will solidify and at even moderately elevated temperatures all fats will liquefy. Moreover, a fat is never entirely solid except under unique circumstances. Fats have been defined as plastic solids consisting of a mixture of crystalline particles and liquid oil.

Lipid (lipide) is a much broader term that may be used to include all the ether-soluble, water-insoluble substances obtainable from plant and animal sources. W. R. Bloor's definition (1943) of lipids has been accepted generally in the United States. A modified and abbreviated form follows: (1) Simple lipids are esters of fatty acids and various alcohols, classified as (*a*) fats and oils, *i.e.*, glycerides (fatty acid esters of glycerol); and (*b*) waxes, *i.e.*, fatty acid esters of alcohols other than glycerol. (2) Compound lipids are esters of fatty acids and alcohols containing additional groups, divided into (*a*) phospholipids (phosphatides), *i.e.*, fatty acid esters containing a phosphoric acid group (they also usually contain a nitrogenous group); (*b*) glycolipids, *i.e.*, compounds that consist of fatty acids, a carbohydrate and a nitrogen-containing compound but no phosphoric acid group; and (*c*) others, such as sulfolipids and aminolipids. (3) Derived lipids are compounds derived from the preceding groups and having the general properties of the lipids; the derived compounds include (*a*) fatty acids; (*b*) alcohols, including glycerol, sterols and the long-chain alcohols from the waxes; and (*c*) others, such as some hydrocarbons like squalene found in fish livers, and nitrogenous bases from the phospholipids.

The fats comprise one of the three great classes of food. Nearly all cells contain fat, protein and carbohydrate. Fat is sometimes called nature's storehouse of energy because on a weight basis it contains more than twice as much energy as does carbohydrate or protein. It is probably as depots of concentrated energy that fats appear in plant reproductive organs such as pollen grains and seeds. It is this fat that man recovers from plants for use as food or in industry. The fat content of the nonreproductive tissue of plants is usually so low that recovery is impracticable. Yet much of man's dietary fat comes from natural foodstuffs without being separated from the other plant materials with which it occurs. The proportion of fat in these foodstuffs varies from 0.2% in white potatoes to 70% in some nut kernels.

More than 90% of the fat recovered in the world is obtained from about 20 species of plants and animals. Most of this separated fat is used eventually as human food. Consequently, fat technology deals largely with the separation and processing of fats into forms acceptable to the various dietary customs in the countries in which they are to be used.

History of Use.—Man has used many natural fats for both food and nonfood purposes since prehistoric times. The Egyptians, for example, used olive oil as a lubricant to aid the moving of heavy building materials. They also made axle greases from fat and lime mixed with other materials for use on chariots as early as 1400 B.C.

George Sarton in *Introduction to the History of Science* (1931) gives many examples of the early use of fats up to the middle ages. Homer mentioned oil as an aid to weaving and Pliny talked about hard and soft soaps. Candles and lamps using oil, tallow or beeswax have been used for thousands of years.

Waxes and oils that dried to hard films were used in protective or decorative coatings on walls and mummy cases, and as waterproofing agents on ships at early dates. The form of painting known as encaustic employed a mixture of pigments in natural waxes. Tempera, another early form of painting, might be considered a forerunner of the modern emulsion paints. It was a water emulsion of wax or oil and pigments stabilized with vegetable gums or egg yolk.

Apparently the first mention of the use of a drying oil as a protective coating was made by Aetius in about the 6th century A.D., when he commented that certain nut oils dry to form a protective coating. Following that period, the art grew rapidly. Transparent varnishes were made of linseed oil and natural resins. However, chemical driers were not used until much later when Hubert and Jan van Eyck reportedly used them in the early 15th century.

The primary basic uses of fats for nonedible purposes remain much the same as centuries ago although the efficiencies and proficiencies of use have improved. The commercial uses of fats have increased in number as understanding of the chemical nature of fats has expanded. K. W. Scheele discovered in 1779 that glycerol could be obtained from olive oil by heating it with litharge, but it was not until about 1815 that Michel Eugène Chevreul (1786–1889) proved the chemical nature of fats and oils, which he described in his classical work, *Recherches chimiques sur les corps gras d'origine animale* (1823, reprinted 1889). At about the same time (1819) J. J. E. Poutet isomerized oleic acid to elaidic acid, and C. A. Gusserow (1828) separated unsaturated liquid acids from the solid acids. After World War I organic chemists gained extensive knowledge first of fatty acid compositions and then of glyceride compositions. Growth of the chemical industry stimulated a simultaneous expansion of the use of fats as raw materials and as intermediates for scores of new chemicals. Modern application of many organic chemical reactions to fats and fatty acids formed the foundation of a new and rapidly growing fatty chemicals industry.

Functions in Plants and Animals.—The universal distribution of fats in plant and animal tissues suggests physiological roles that go beyond their function as a fuel supply for the cells. In animals the most evident function of fats is that of food reserve to supply energy (through subsequent enzymatic oxidation). The storage of fat in vegetable seeds can be similarly explained on the basis that it is a food reserve for the embryo. However, it is not so easy to account for the presence of large quantities of fat in the pericarp of such fruits as olives, avocados and palms; this fat is probably destroyed before the seed germinates.

Fats, and especially the waxes, fulfill other valuable functions in plants and animals. Subcutaneous deposits of fat insulate animals against cold because of the low heat transfer rate of fat, a property especially important for animals living in cold waters or climates, *e.g.*, whales, walruses and bears. Beeswax prevents dilution or contamination of concentrated sugar solutions in the comb. Waxes, and in some cases fats, secreted on the surface of plant leaves protect the underlying tissues against loss of or access of water. Apples, citrus fruits and melons have a natural protective wax coating.

Fats that have been separated from tissues always contain small quantities of closely associated nonglyceride lipids such as phospholipids, sterols, vitamins A, D and E, and various carotenes

and carotenoids. Many of these substances are vital emulsifying agents or growth factors. These minor constituents probably are present in the fats as a result of their physical solubility, and thus fats serve as carriers for these substances in animal diets.

Many animals require some fat containing one or more of the essential fatty acids (linoleic, linolenic and arachidonic) to prevent the physical symptoms of essential fatty acid deficiency manifested by skin lesions, scaliness, poor hair growth and low growth rates. The so-called essential fatty acids must be supplied in the diet since they cannot be synthesized in the body.

Synthesis and Metabolism in Living Organisms.—Formation of fats in seeds and fruits occurs late in the ripening process. Sugars and starches predominate in fruits, seeds and sap in the unripe condition. These apparently are converted by enzymatic direction during the maturing process to fatty acids and glycerol, which then form glycerides. Studies with radioactive tracer techniques confirmed the synthesis of fats from carbohydrates in both plants and animals. In fact, it was shown by the use of labeled acetate that any food source from which acetate may form as an intermediate metabolite can thus be converted to fatty acids in at least some animal tissues. It was further demonstrated that acetate can be converted to cholesterol in animal tissue. It is noteworthy that, almost without exception, natural fats contain only fatty acids with an even number of carbon atoms. These acids apparently are built up of two-carbon units. Although the preponderance of 18-carbon fatty acids had suggested the hypothesis that fats are derived from the C_{18} nucleus of polysaccharides or perhaps from three molecules of glucose, discoveries through tracer studies seem to indicate the build-up from the two-carbon acetate units. Since acetate can be formed in oxidative processes from fats, proteins or carbohydrates, it is thus possible for fats to be synthesized indirectly from any of these sources. The formation of double bonds in the fats synthesized from acetate is accomplished (probably in the liver) by various enzymatic dehydrogenation and hydrogenation systems.

Utilization of stored fat by plant embryos had not been entirely explained by the 1960s. However, it was found that in germinating embryos the glycerides are hydrolyzed by lipolytic (fat-splitting) enzymes to glycerol and fatty acids. These may pass through two- and four-carbon oxidative processes to form intermediate metabolic products that can be oxidized further to carbon dioxide and water or can be converted to carbohydrates, which may then pass through the many steps of carbohydrate metabolism.

In animal digestive tracts, the fats in foods are emulsified with digestive secretions containing lipase, which hydrolyzes at least part of the glycerides. The glycerol, partial glycerol esters, fatty acids and some glycerides then are absorbed through the intestinal epithelium and are at least partially recombined to form glycerides and phospholipids. The fat, in the form of microscopic droplets, or chylomicrons, is transported in the blood and chyle to points of use or storage. The fat of an individual animal may vary according to the composition of fats in the food. For instance, body fats of swine that were fed cod-liver oil had soft fats characteristic of the diet, and cows receiving coconut oil or fish oil produced milk fats similar to the dietary sources. Fats used by or stored in animal tissues come from two sources—diet and enzymatic synthesis. Thus, the endogenous fat enzymatically synthesized from carbohydrates or proteins is characteristic of the species of animal, whereas, the exogenous fat resynthesized from the food fats is characteristic of the dietary fat. Mammary glands apparently have enzymatic systems that can produce fats quite different from those stored in adipose tissue. Even so, milk fats still can reflect characteristics of ingested fats.

The manner in which fat reserves are circulated to the organs where metabolism occurs is incompletely understood. Radioactive tracer studies provided some insight into this complicated process. It has long been established that when mobilization of reserve fat takes place the stream is directed primarily to the liver, where fatty acids may be partially desaturated; *i.e.*, hydrogen is removed from the fatty acid chains to produce unsaturated linkages. This facilitates subsequent oxidation in other tissues. Fatty acids also may be oxidized directly in the various tissues as well as in the liver. Fatty acid metabolism is presumed to be by oxidation in successive two- and four-carbon stages. Intermediate products could be acetoacetate and acetate groups. If the mechanism is faulty, acetone is formed and excreted (acetonuria). The final products of normal metabolism are carbon dioxide and water. (*See* also BIOCHEMISTRY: *Fats and Amino Acids*; METABOLISM: *Fats*.)

Chemical Composition of Fats.—Although natural fats consist primarily of glycerides, they contain many other lipids in minor quantities. For example, corn oil may contain glycerides plus phospholipids, glycolipids, phosphoinositides (phospholipids containing inositol), many isomers of sitosterol (a plant steroid), several tocopherols (vitamin E), vitamin A and dozens of carotenoids and chlorophyll compounds, as well as many products of decomposition, hydrolysis, oxidation and polymerization of any of the natural constituents.

Since the glycerides, which make up 90% to 99% of most individual fats or oils of commerce, are esters formed by three fatty acid molecules combining with one molecule of glycerol, they may differ not only in the fatty acids that they contain but also in the arrangement of the fatty acid radicals on the glycerol moiety. Simple triglycerides are those in which each molecule of glycerol is combined with three molecules of one acid, *e.g.*, tripalmitin, $C_3H_5(O{\cdot}CO{\cdot}C_{15}H_{31})_3$, the glyceryl ester of palmitic acid, $C_{15}H_{31}COOH$. Only a few of the glycerides occurring in nature are of the simple type; most are mixed triglycerides; *i.e.*, one molecule of glycerol is combined with two or three different fatty acids. Thus, stearodipalmitin, $C_3H_5(O{\cdot}CO{\cdot}C_{15}H_{31})_2(O{\cdot}CO{\cdot}C_{17}H_{35})$, contains two palmitic acid radicals and one stearic acid radical. Likewise, oleopalmitostearin, $C_3H_5(O{\cdot}CO{\cdot}C_{15}H_{31})(O{\cdot}CO{\cdot}C_{17}H_{33})(O{\cdot}CO{\cdot}C_{17}H_{35})$, contains one radical each of oleic, palmitic and stearic acids. Each mixed triglyceride containing three different acid radicals has three different isomeric forms depending on which acid is linked with the centre carbon

TABLE I.—*Common Fatty Acids*

Common name	Systematic name	Formula	Carbon atoms	Double bonds
Caprylic	Octanoic	$C_7H_{15}COOH$	8	0
Capric	Decanoic	$C_9H_{19}COOH$	10	0
Lauric	Dodecanoic	$C_{11}H_{23}COOH$	12	0
Myristic	Tetradecanoic	$C_{13}H_{27}COOH$	14	0
Palmitic	Hexadecanoic	$C_{15}H_{31}COOH$	16	0
Stearic	Octadecanoic	$C_{17}H_{35}COOH$	18	0
Arachidic	Eicosanoic	$C_{19}H_{39}COOH$	20	0
Oleic	9 Octadecenoic	$C_{17}H_{33}COOH$	18	1
Linoleic	9,12 Octadecadienoic	$C_{17}H_{31}COOH$	18	2
Linolenic	9,12,15-Octadecatrienoic	$C_{17}H_{29}COOH$	18	3
Eleostearic	9,11,13-Octadecatrienoic	$C_{17}H_{29}COOH$	18	3
Ricinoleic	12 OH,9 Octadecenoic	$C_{17}H_{32}OCOOH$	18	−OH+1
Arachidonic	5,8,11,14-Eicosatetraenoic	$C_{19}H_{31}COOH$	20	4

(β-position) of the glycerol molecule and which acids are in the outside (α or α') positions. Similarly, each mixed triglyceride containing two radicals of one acid and one radical of a second acid has two isomeric forms.

Monoglycerides and diglycerides have only one or two fatty acid radicals, respectively, and are seldom found in natural fats except as the products of partial hydrolysis. However, they are easily prepared synthetically and have important applications mainly because of their ability to aid in the formation and stabilization of emulsions. As constituents of shortening in baked products they increase loaf volumes and retard staling.

The characteristics of glycerides are determined by their component acids. In considering the composition of a glyceride it is particularly important to distinguish between the saturated acids (such as palmitic or stearic, which have relatively high melting temperatures), and the unsaturated acids (such as oleic or linoleic, which are low melting and chemically much more reactive because of their double bonds). (For a discussion of the difference between saturation and unsaturation *see* HYDROCARBON: *General Structure*.)

The glyceride composition of natural fats tends to follow the rule of even distribution developed by T. P. Hilditch and his

TABLE II.—*Saturation and Unsaturation in Fatty Acids*

CH_3-CH_2-CH_2-CH_2-CH_2-CH_2-CH_2-CH_2-CH_2-CH_2-CH_2-$COOH$
Lauric acid
(A saturated fatty acid with 12 carbon atoms)
$CH_3(CH_2)_7CH=CH(CH_2)_7COOH$
Oleic acid
(An unsaturated fatty acid with one double bond and 18 carbon atoms)
$CH_3(CH_2)_4CH=CHCH_2CH=CH(CH_2)_7COOH$
Linoleic acid
(An unsaturated fatty acid with two double bonds and 18 carbon atoms)
$CH_3CH_2CH=CHCH_2CH=CHCH_2CH=CH(CH_2)_7COOH$
Linolenic acid
(An unsaturated fatty acid with three double bonds and 18 carbon atoms)

Arachidonic acid
(An unsaturated fatty acid with four double bonds and 20 carbon atoms)

associates, who proposed that each of the individual fatty acid radicals in a fat is apportioned evenly among the different glyceride molecules. Consequently, specific acids present in quantities less than one-third of the total acids are inclined to appear singly in the glycerides, and it is necessary to have an acid present in a quantity greater than two-thirds of the total acids before any simple triglycerides would be present. Vegetable seed fats tend to follow this rule much more closely than do animal fats. The latter even tend to have their saturated acids closely grouped. Beef tallow may contain 15% of simple fully saturated triglycerides even though it contains only 55% of saturated fatty acids.

Some fats tend to follow the pattern of random distribution of fatty acids in their glycerides. In this pattern, the acids are distributed among the glycerides as if there were no directing influences and they had organized themselves by chance alone. Fats that are heated in the presence of certain alkaline catalysts, such as sodium methylate (sodium methoxide), "rearrange" themselves to follow more closely the system of random distribution. Physical properties are often significantly altered. For example, some shortening manufacturers in the United States rearrange the molecules in lard and other fats to make improved shortenings.

Physical and Chemical Properties.—Fats and oils may be divided into animal and vegetable fats according to source. Further, they may be classified according to their degree of unsaturation as measured by their ability to absorb iodine at the double bonds. This degree of unsaturation determines to a large extent the ultimate use of the fat as shown in Table III. Oils having iodine values higher than about 150 (and therefore a high degree of unsaturation) are generally called drying oils and are used primarily in protective coatings Those having iodine values of 100 to 150 are considered as semidrying and may be used either for food or in protective coatings. The nondrying oils, with the lowest amount of unsaturation, have iodine values generally below 100 and are used mainly in foods, soaps, chemicals and specialty products.

As indicated in Table III, liquid fats (*i.e.*, vegetable and animal oils) have the highest degree of unsaturation, while solid fats (vegetable and animal fats) are highly saturated. The degree of unsaturation in fatty acids used as foods drew wide attention in the 1960s because of the possible relationship between saturated fats, cholesterol and atherosclerosis. Some authorities suggested that the amount of unsaturated fats in the diet should be increased as a means of reducing the incidence of atherosclerosis. Dietary interest was focused on the polyunsaturated fatty acids—those with two or more double bonds in each molecule. The chief polyunsaturated acids considered in this connection were linoleic (two double bonds), linolenic (three) and arachidonic (four). The oils with the highest ratios of polyunsaturated to saturated (P/S ratio) acids are, in decreasing order, safflower, corn, cottonseed and soybean.

Solid vegetable fats melting between 20° and 35° C. are found mainly in the kernels and seeds of tropical fruits. They have relatively low iodine values and consist of glycerides containing high percentages of saturated acids such as lauric, myristic and palmitic. Fats from fruits of many members of the palm family, notably coconut and babassu oils, contain large amounts of combined lauric acid. Most animal fats are solid at ordinary temperatures; milk fats are usually characterized by the presence of short-chain carboxylic acids (butyric, caproic and caprylic).

Specific gravities of oils and fats range from 0.913 (rape oil) to 0.975 (Japan wax, myrtle wax); for most fats the value is 0.915 to 0.945. Some oils that contain acids with asymmetric carbon atoms, notably those of the castor oil and chaulmoogra groups, rotate the plane of polarized light.

Fats are practically insoluble in water and, with the exception of castor oil, are insoluble in cold alcohol and only sparingly soluble in hot alcohol. They are soluble in ether, carbon disulfide, chloroform, carbon tetrachloride, petroleum benzin and benzene. Oils and fats have no distinct melting points or solidifying points because they are such complex mixtures of glycerides having dif-

TABLE III.—*Sources, Iodine Value and Uses of Principal Oils and Fats*

Oil or Fat	Principal sources of raw material	Iodine value	Principal uses
Vegetable Oils			
Drying oils			
Perilla	China, Korea, Japan, India	193–208	Paint, varnish
Linseed	Argentina, India, North America, U.S.S.R.	175 205	Paint, varnish, linoleum, printing ink
Tung	China, Japan, U.S.	160–175	Paint, varnish
Oiticica	Brazil	139–155	Paint, varnish
Semidrying oils			
Poppyseed	Levant, India	123–143	Salad oil, artists' oil, soft soap
Safflower	U.S., India	130–150	Salad oil, paints, resins
Soybean	U.S., China, Manchuria	125–140	Food, paint, resins, chemicals
Maize (corn)	U.S., Argentina, Europe	115–130	Food
Sunflower	South America, U.S.S.R.	120–140	Food
Cottonseed	U.S., India, Egypt, Mexico	100 116	Food, soap
Sesame	India, etc., Egypt, Levant	103–118	Food, soap
Rape (colza)	E. India, Europe	94–102	Food, lubricant
Nondrying oils			
Almond	S. Europe, N. Africa	93–100	Perfumery, pharmacy, food
Arachis (peanut)	India, W. Africa, China, U.S.	85 100	Food
Olive	Mediterranean countries, U.S.	75–95	Food, soap, lubricating, pharmacy
Castor	E. India, Mediterranean, Brazil, U.S.	80–90	Medicine, lubricant, chemicals
Animal and Marine Oils			
Marine oils			
Sardine	West coast of North America, Japan	170–190	Resins, leather currying, linoleum, paints, food
Menhaden	Atlantic coast of North America	140–173	
Herring	North Sea, Japan	120 145	Leather currying, paints, food
Cod liver	North Sea, E. coast North America	120–180	Vitamins, leather currying
Shark liver	Coasts of North America	100 115	Vitamins, leather currying
Seal	Arctic and Antarctic seas	127–147	Food, leather currying, soap
Whale	Arctic and Antarctic seas	110–150	Food, soap, fibre dressing, leather currying, greases
Dolphin, jaw and body oils	. . . .	33, 99–126	Lubricating oil for delicate machinery
Porpoise, jaw and body oils	. . . .	36, 119	
Terrestrial animal oils			
Neat's-foot	U.S., South America, Europe	65–75	Lubricating, high-grade leather dressing
Vegetable Fats			
Mahua (Illipé) butter	India, Malaya	53–67	Food, soap, candles
Shea butter	W. Africa, Sudan	53–65	Food, soap, candles
Palm oil	W. Africa	50–60	Soap, candles, tinplate industry
Cacao (cocoa) butter	W. Indies	32–41	Chocolate, pharmacy, perfumery
Babassu oil	W. Africa	9–18	Food, soap
Coconut oil	Philippine Islands, E. Indies, Ceylon, Oceania, South American coasts	8–10	Food, soap, chemicals
Japan wax	China, India, Japan	5–17	Polishes
Animal Fats			
Lard	U.S., Central Europe	45 70	Food, soap, pharmacy, chemicals
Bone	U.S., India, Europe	46–56	Soap, candles
Tallow, beef	Argentina, U.S.	30–45	Food, soap, candles, chemicals
Tallow, mutton	Australasia	25–45	Food, soap
Butter	U.S., N.W. Europe, Australasia, Canada	25–40	Food

TABLE IV.—*Fatty Acid Composition of Certain Fats and Oils*
(Numbers represent percentage by weight of total fatty acid content)*

Fatty acids	Normally Solid Fats								Vegetable Oils														Marine oils

*These are typical data compiled from many sources; specific analyses vary considerably depending on the source of the fat or oil.
†43%–57% erucic acid. ‡73%–83% licanic acid. §13%–18% palmitoleic, 10%–20% C_{20}, 5%–12% C_{22} unsaturated acids. ‖High percentages of C_{18}, C_{20} and C_{22} acids with two, four and six double bonds.

ferent melting points. Glycerides themselves, further, have several polymorphic forms with different melting or transition points. The freezing points of the oils range from a few degrees above zero to about 30° C. below zero. At low temperatures (*e.g.*, 12° C. for cottonseed oil), solid portions, termed tristearin, or stearin, separate from many oils. The tristearin is filtered or settled out; the clear fraction, which will remain limpid at low temperatures, is called winter oil, or winterized oil.

Fats can be heated to between 200° and 250° C. without undergoing significant changes provided contact with air or oxygen is avoided. On being heated above this temperature the more unsaturated oils gradually polymerize and become considerably more viscous. When this is done commercially in the protective coating industry it is called bodying. Castor oil, when heated to high temperature or under suitable conditions in the presence of catalysts, loses a molecule of water from each ricinoleic acid radical to form what is called dehydrated castor oil. Above 300° C. fats may decompose with the formation of acrolein (decomposition product of glycerol), which has the pungent odour of burning fat. Hydrocarbons also may be formed at high temperatures.

On exposure to air, oils and fats gradually undergo certain changes. The drying oils absorb oxygen (dry) and polymerize readily; thin layers form a skin or protective film. The semidrying oils absorb oxygen more slowly and are less useful as paint oils; still, sufficient oxygen is absorbed in time to produce distinct thickening and some film formation. Oxidation of the semidrying oils is accelerated by spreading the oil over a large surface; on greasy cloths, for example, oxygen absorption may proceed so rapidly that spontaneous combustion ensues. The nondrying oils, of which olive oil is typical, do not oxidize readily on exposure to air although changes do take place gradually, including slow hydrolysis (splitting to fatty acids and glycerol) and subsequent oxidation. This slow oxidation causes disagreeable smell and taste described by the term rancidity. The chemical reactions involved have been widely studied. Numerous antioxidants (*q.v.*) retard the oxidation leading to rancidity.

Fats are readily hydrolyzed. This property is extensively used in the manufacture of soaps and in the preparation of fatty acids for industrial applications. Fats are hydrolyzed by treatment with water alone under high pressure (corresponding to a temperature of about 220° C.) or with water at lower pressures in the presence of caustic alkalies, alkaline earths or basic metallic oxides that act as catalysts. Free fatty acids and glycerol are formed. If sufficient alkali is present to combine with the fatty acids, the corresponding salts (known popularly as soaps) of these acids are formed, such as the sodium salts (hard soap) or potassium salts (soft soaps). (For detailed descriptions of the methods employed in commercial hydrolysis, *see* CANDLE; SOAP.)

Extraction.—Fats may be recovered from oil-bearing tissues by three general methods with varying degrees of mechanical simplicity: (1) rendering; (2) pressing with mechanical presses; and (3) extracting with volatile solvents.

Rendering.—The crudest method of rendering oil from oleaginous fruits, still practised in some countries, consists of heaping them in piles, exposing them to the sun and collecting the oil that exudes. In a somewhat improved form this process is used in the preparation of palm oil; the fresh palm fruits are boiled in water and the oil is skimmed from the surface. Such processes can be used only with seeds or fruits (such as olive and palm) that contain large quantities of easily released fatty matter. The rendering process is applied on a large scale to the production of animal fats such as tallow, lard, bone fat and whale oil. It consists of cutting or chopping the fatty tissue into small pieces, which are boiled in open vats or cooked in steam digesters. The fat is gradually liberated from the cells and floats to the surface of the water, where it is collected by skimming. The membranous matter (greaves) is separated from the aqueous (gluey) phase by pressing in hydraulic or screw presses; additional fat is thereby obtained. The residue is used for animal feed or fertilizer.

Pressing.—With many oil-bearing seeds and nuts, rendering will not liberate the oil from the cellular structures in which it is held. In these cases the cell walls are broken by grinding, flaking, rolling or pressing under high pressures to liberate the oil. Many different mechanical devices have been used. The most primitive method was to crush seed in mortars until the oil exuded. The lever and wedge, one step more advanced and employed for centuries, are still used in some primitive places. The Romans developed a screw press, which Pliny described, for the production of olive oil. Centuries ago, the Chinese employed the same series of operations followed in modern pressing mills, viz., bruising or grinding the seeds in stone mills, heating the meal in open pans, then pressing out the oil in a wedge press. The Dutch or Stamper press invented in the 17th century was used almost exclusively in Europe for pressing oilseeds until the early part of the 19th century, when the hydraulic press was developed. The modern screw press replaced many of the hydraulic presses because it is a continuous process, has greater capacity, requires less labour and will generally remove more oil.

The general sequence of modern operations in pressing oilseeds, nuts, etc., is as follows: (1) remove all loose metal by passing the seeds over magnetic separators; (2) decorticate where necessary and remove the shells or hulls; (3) convert the kernels or meats to coarse meal by grinding between grooved rollers or with special types of hammer mills; and (4) press in hydraulic or screw presses with or without preliminary heating, depending on the type of oil-

bearing material and the quality of oil desired. Oil expressed without heating contains the least amount of impurities and is often of edible quality without refining or further processing. Such oils are known as cold-drawn, cold-pressed or virgin oils. Pressing the coarse meal while it is heated removes more oil and also greater quantities of nonglyceride impurities such as phospholipids, colour bodies and unsaponifiable matter. Such oil is more highly coloured than cold-pressed oils. Residual meals are generally used for cattle feed or fertilizer.

Solvent Extraction.—Cakes obtained by pressing operations still retain 3% to 15% of residual oil. In cases where the value of the oil is considerably greater as oil than as a part of the meal, it is desirable to obtain more complete extraction with solvents. Modern commercial methods of solvent extraction use volatile purified hydrocarbons, especially the various grades of petroleum benzin (commonly known as petroleum ether, commercial hexane or heptane). The use of chlorinated solvents to decrease the fire and explosion hazard did not prove satisfactory. Trichloroethylene was used in several plants until it was found that it reacted with some meals, *e.g.*, soybean meal, and made them toxic to some animals. In large-scale operations solvent extraction is a more economical means of recovering oil than is mechanical pressing. In the United States there are many instances of simple petroleum benzin extraction of seeds, mainly soybeans. For seeds or nuts containing a higher oil content than soybeans it became customary to press the material in screw presses to remove a large proportion of the oil before extraction. Prepressing also ruptures the cellular structures of oil-bearing materials so that most of the residual oil is easily removed with solvents.

A typical extraction system consists of (1) removing hulls or cortex in cracking, aspirating or screening operations; (2) cracking or rough grinding the kernels, meats or prepressed cake; (3) flaking the small pieces between smooth flaking rolls; (4) extracting the oil with solvent; (5) separating the meal, or marc, from the oil-solvent solution, called miscella; and (6) removing the solvent from both the oil and the marc. The marc may be toasted or pelletized, or both, for use in animal feeds. Most extracted meals contain less than 1% of residual oil. The percentage varies depending upon the amount of prepressing, the type of material being extracted and the efficiency of the extracting system.

An interesting combination of solvent extraction and rendering is the azeotropic rendering process. In this process, a chlorinated solvent is mixed with wet fresh tissue and the mass is heated to the boiling point of the azeotropic mixture of solvent and water. When condensation occurs, the azeotrope separates; water is drawn off and the solvent is returned to the extraction system. The resulting product consists of a dry (low moisture) extracted meal and miscella containing most of the fat. The high cost of chlorinated solvents proved a disadvantage, but the process possesses promising potentialities because of its ability to prepare extracted animal or fish meals that have not been subjected to high temperatures.

Processing.—The extent of processing applied to fats depends upon their source, quality and ultimate use. Many fats are used for edible purposes after only a single processing step—*i.e.*, clarification by settling or filtering. Most cold-pressed oils (for example, cold-pressed olive, peanut and some coconut oils) can be used in food products without further processing. Tremendous quantities of butter and lard are used without special treatment after churning or rendering. However, the growing demand for bland-tasting and stable salad oils and shortenings led to extensive processing techniques. But, in the less industrialized countries processing often is limited by lack of facilities and added costs.

Refining.—The nonglyceride components contribute practically all of the colour and flavour to fats. In addition, such materials as the free fatty acids, waxes, colour bodies, mucilaginous materials, phospholipids and gossypol (a yellow pigment found only in cottonseed oil) contribute other undesirable properties in fats used for edible purposes and to some extent for industrial applications. Many of these can be removed by treating the fats at 40° to 85° C. with an aqueous solution of caustic soda (sodium hydroxide) or soda ash (sodium carbonate). The refining may be done in a tank (in which case it is called batch or tank refining) or in a continuous system. In the former system the aqueous emulsion of soaps formed from free fatty acids along with other impurities (soapstock) settles to the bottom and is drawn off. In the continuous system the emulsion is separated with centrifuges. After the fat has been refined, it is usually washed with water to remove traces of alkali and soapstock. Oils that have been refined with soda ash or ammonia generally require a light rerefining with caustic soda to improve colour. After water-washing, the oil may be dried by heating in a vacuum or by filtering through a dry filter aid material. The refined oil may be used for industrial purposes or may be processed further to edible oils. Usually, the refined oils are neutral (*i.e.*, neither acidic nor alkaline), free of material that separates on heating (break material), lower in colour, less viscous and more susceptible to rancidity.

Other refining techniques that have been employed include the use of sulfuric acid instead of alkaline agents. This technique removes or destroys many of the impurities in the oils without removing the free fatty acids. For industrial oils, such as linseed oil, that are not required to be low in fatty acids, acid refining is sometimes advantageous. Steam refining, consisting of blowing clean steam through oil at high temperature and under vacuum, may sometimes be used on oils, such as coconut oil, that contain few phospholipids or other impurities; or it may be used on oils that have been treated with acetic anhydride to remove the phospholipids and other impurities. Steam blowing removes most of the free fatty acids. Other refining agents that have been used include petroleum benzin, ammonia, magnesium and calcium oxides, ion exchange resins and certain organic bases.

Water refining, usually called degumming, consists of treating the natural oil with a small amount of water followed by centrifugal separation. It is applied to many oils that contain phospholipids in significant amounts. Its purpose may be to recover the phospholipids or to degum the oil, or both. Phospholipids from oils such as corn (maize) and soybean oils may be dried (commercially, these products are called lecithin) and used as emulsifiers in such products as margarine, chocolate products and emulsion paints. The degummed oil may be used directly in industrial applications, such as in paints or alkyd resins, or refined with alkalies for ultimate edible consumption.

Bleaching.—In cases where further colour removal is desired, the fat may be treated with any of dozens of chemical and physical bleaching agents. Chemical treatments include the use of air and light, sodium dichromate and acid, permanganates, hypochlorites, metallic persalts and peroxides. They are not usually used on products destined for edible purposes. Physical adsorption methods involve treating hot oils with activated carbons, fuller's earths or activated clays. Many impurities including chlorophyll and carotenoids are adsorbed onto the agents and removed by filtration. Bleaching by any of these means reduces the resistance of oils to rancidity. When many oils are heated to more than 175° C., a phenomenon known as heat bleaching takes place. Apparently the heat decomposes some pigments, such as the carotenoids, that are present.

Destearinating or Winterizing.—It is often desirable to remove the traces of waxes (probably cuticle wax from seed coats) and the higher-melting glycerides from fats. Waxes can generally be removed by rather rapid chilling and filtering. Separation of tristearin, or stearin, usually requires very slow cooling in order to form crystals that are large enough to be removed by filtration. Thus linseed oil may be winterized to remove traces of waxes that otherwise interfere with its use in paints. Tristearin may be removed from fish oils to separate the solid glycerides that would detract from its use in paints and alkyd resins. At the same time, fish tristearin is more suitable than whole oil for edible purposes. Cottonseed and peanut oils may be destearinated to produce salad oils that remain liquid at low temperatures. Tallows and hydrolyzed animal fats may be destearinated for simultaneous production of hard fats (high in stearic acid content for special uses such as in making candles) and of liquid oil called oleo oil.

Hydrogenation.—For most edible purposes and for some com-

mercial applications it is desirable to produce solid fats. Many shortenings and margarines contain hydrogenated (hardened) oils as their major ingredients. The development of margarine and shortening products resulted from the invention by Wilhelm Normann of a successful method for converting low-melting unsaturated fatty acids and glycerides to higher-melting saturated products. The process consists of the general reaction discovered by P. Sabatier and J. B. Senderens of the addition of hydrogen in the presence of a catalyst to the double (unsaturated) bonds. Thus, oleic or linoleic acid (or their acid radicals in glycerides), which are normally liquid at room temperature, can be converted to stearic acid or the acid radical by the addition of hydrogen.

In commercial practice, hydrogenation is usually carried out with vigorous agitation or hydrogen dispersion with a narrow range of catalyst concentration (about 0.05% to 0.10% of finely divided nickel suspended on kieselguhr, or diatomaceous earth) in a steel pressure reacting vessel. The ordinary ranges of temperature and pressure are 100° to 200° C. and 0 to 60 lb. per square inch, respectively. These conditions can be controlled to make the hydrogenation reaction somewhat selective; *i.e.*, to add hydrogen to the linolenic (three double bonds) and linoleic (two double bonds) acid radicals before adding to the oleic (one double bond) acid radicals. The most unsaturated fatty acid groups are most easily hydrogenated and thus react first with the hydrogen if conditions are right. In cases where very hard fats with low amounts of unsaturation are desired and selectivity is unimportant, higher temperatures and pressures are employed to shorten the reaction time and to use partially spent catalyst that would otherwise be wasted. After hydrogenation the hot oil is filtered to remove the metallic catalyst for either reuse or recovery.

During the catalytic treatment another reaction also takes place —the isomerization of unsaturated fatty acid radicals to form iso-oleic, isolinoleic, etc., groups. These isomers have higher melting points than do the natural acids. Thus they contribute to the hardening effect. They can be detected by infrared analysis but not by determination of iodine value. (*See* also HYDROGENATION; MARGARINE.)

Uses.—It is virtually impossible to enumerate in detail the many applications of fats. However, in Table III the principal uses of some typical oils and fats are given. Most of the high-quality fats can be and are used for edible purposes such as margarine, shortenings, cooking fats and salad oils. The next largest use for fats is for soap. However, after World War II synthetic detergents manufactured from petroleum products supplanted much of the soap, especially in the United States. Some hard fats, tallows and beeswax are still used in candle manufacture, but petroleum waxes also took over a large share of candle production. Considerable quantities of specialty oils and sulfonated oils are used in leather dressing and textile manufacture. Some oils have properties of medicinal value. For example, castor oil has a strong purgative action; fish liver oils are sources of vitamins A and D; and others such as lard, olive oil and almond oil serve as vehicles in pharmaceutical preparations. Linseed, tung and other drying oils and large quantities of soybean oil are used in paints, varnishes, linoleums (linseed, mainly) and alkyd resins. The latex emulsion paints containing products derived principally from petroleum oil began to find widespread acceptance for interior finishes in the U.S. in the late 1940s. This trend, which spread to other countries in the 1950s and included emulsion paints for outside use, displaced large volumes of the drying oils in protective coatings. Competition of products from petroleum encouraged (and forced) the development of new products and new markets for glyceride oils. Among the new derivatives were drying oil products that could be thinned with water.

A new industry based on the manufacture of chemicals from fats was started just prior to World War II and grew rapidly after the war. Fats were hydrolyzed to glycerol and their fatty acids fractionated by vacuum distillation, by solvent segregation or by both. This made available commercial quantities of relatively pure single fatty acids. From the fatty acids dozens of products such as long-chain alcohols, amines, amides, esters, nitriles and ketones were made. These chemicals could be used for many applications directly or as chemical intermediates in the manufacture of other products such as detergents, plasticizers, special lubricating oils, polyamide resins and special thixotropic (gel) paints. Other modifications of the glycerides themselves through such chemical processes as epoxidation, copolymerization, rearrangement, chlorination, vinylation and acetylation promised more new industrial products.

Production.—The principal countries and regions producing various oil-bearing materials (seeds, nuts, etc.) are given in Table III. In many cases the fats are not extracted in the countries of origin; instead, the raw materials are exported. Thus, Marseilles became a centre for coconut oil trade; Liverpool, Hull and Hamburg-Harburg developed into centres of oilseed expression, etc. However, the development of industry in tropical countries and the high cost of transportation led to increased production of oils and fats in the countries of origin. Statistics on world production of oil-bearing materials and extracted oils are sometimes incomplete, but data are available in the publications of Frank Fehr and Co. (*Annual Review of Oilseed and Oil Markets*, the Congress of International Association of Seed Crushers, the U.S. department of agriculture, the Food and Agriculture Organization of the United Nations and trade returns of various countries.

Waxes.—Waxes differ from fats chemically in that they are fatty acid esters of monohydroxy alcohols instead of glycerol. A few are esters of dihydroxy alcohols. Moreover, their physiological function as a protective coating on cuticles of leaves and fruit appears to be different from that for fats because waxes rarely occur as cell constituents. The waxes are difficult to saponify in contrast with the relative ease of saponification or hydrolysis of glycerides. Many of the waxes melt at high temperatures (*i.e.*, between about 35° and 100° C.) and form hard films that can be polished to a high gloss; therefore, they are used in many kinds of polishes. Their other physical properties are similar to those of the fats. They are soluble in the same solvents and leave grease spots on paper.

TABLE V.—*Some Alcohols and Fatty Acids Found in Natural Waxes*

Name	Formula	Wax
Palmitic acid	$C_{15}H_{31}COOH$	Spermaceti, beeswax, Japan wax
Cerotic acid	$C_{25}H_{51}COOH$	Beeswax, montan wax, carnauba
Melissic acid	$C_{29}H_{59}COOH$	Beeswax, montan wax
Cetyl alcohol	$C_{16}H_{33}OH$	Spermaceti, porpoise oil
Octadecyl alcohol	$C_{18}H_{37}OH$	Spermaceti
Oleyl alcohol	$C_{18}H_{35}OH$	Spermaceti, porpoise oil
Ceryl alcohol	$C_{26}H_{53}OH$	Insect wax
Myricyl alcohol	$C_{30}H_{61}OH$	Beeswax, carnauba wax
Cholesterol		Wool wax

The fatty acids found in waxes are almost always saturated. They vary from lauric to octatriacontanoic ($C_{37}H_{75}COOH$). The saturated alcohols of the $C_nH_{2n+2}O$ series from C_{12} to C_{36} have been identified in various waxes. Several dihydric (two hydroxyl groups) alcohols have been separated, but they do not form a large proportion of any wax. Also, several unidentified branched-chain fatty acids and alcohols have been found in minor quantities. Several cyclic sterols (cholesterol and analogues) make up major portions of wool wax.

Only a few vegetable waxes are produced in commercial quantities. Carnauba wax, which is very hard and is used in some high-gloss polishes, is probably the most important of these. It is obtained from the surface of the fronds of a species of palm trees native to Brazil. A similar wax, candelilla wax, is obtained commercially from the surface of the candelilla plant, which grows wild in Texas and Mexico. Sugar cane wax, which occurs on the surface of sugar cane leaves and stalks, is obtainable from the sludges of cane juice processing. Its properties and uses are similar to those of carnauba wax, but it is normally dark in colour and contains more impurities. Commercial production of other waxes such as rice wax and grain sorghum wax proved unsuccessful. Other cuticle waxes occur in trace quantities in vegetable oils such as linseed, soybean, corn (maize) and sesame. They are undesirable because they may precipitate when the oil stands at room temperature, but they can be removed by cooling and filtering. Cuticle wax accounts for the beautiful gloss of polished apples.

Beeswax, the most widely distributed and important animal wax, is softer than the waxes mentioned above and finds little use in gloss polishes. However, it is used for its gliding and lubricating properties as well as in waterproofing formulations.

Wool wax, the main constituent of the fat that covers the wool of sheep, is obtained as a by-product in scouring raw wool. When it is purified it is called lanolin and is used as a pharmaceutical or cosmetic base because it is easily assimilated by the human skin. Sperm oil and spermaceti, both obtained from sperm whales, are liquid at ordinary temperatures and are used mainly as lubricants.

OIL SHALE: *see* FUELS: *Liquid Fuels: Carbonization.*

OISE, a *département* of northern France, was formed in 1790 mainly from northern districts of the historic Île-de-France (*q.v.*), with the addition of adjacent parts of Picardy (*q.v.*). It is bounded north by Somme, east by Aisne, south by Seine-et-Marne and Val-d'Oise, and west by Eure and Seine-Maritime. Area 2,261 sq.mi. Pop. (1962) 481,289. The *département* is traversed from northeast to southwest by the middle course of the Oise river from above Noyon, past Compiègne, where it receives the Aisne, its most important tributary, to below Creil. To the southeast, where residual sands overlie the Tertiary limestone platform, are extensive forests (Compiègne, Senlis and Chantilly) with summer retreats and outlying residential settlements for Parisians. In the forest of Compiègne the spot where the armistice was signed in Nov. 1918 is commemmorated. Northwest of the Oise valley the chalk appears from beneath the Tertiary rocks along an irregular margin and the ground rises up the valley of the Thérain tributary to the hills of Bray. Wheat, sugar beet and fodder crops are extensively grown, especially where cappings of *limon* provide rich soil, and a heavy density of cattle is maintained. Along the valley floors are meadows and market gardens. By the Oise there is contact with the Seine system and with the waterways of the industrial northeast. Creil, on the Oise, is an industrial town with a large electric-power station, and, with neighbouring Montataire, it has metallurgical industries. At Thourotte Chantereine there are glassworks, and elsewhere a variety of light industries is represented. The textile industry is important at Beauvais (*q.v.*), which also manufactures brushes, combs, buttons, and other articles of ivory, bone, mother-of-pearl and plastics. Beauvais, the departmental capital, is the centre of the bishopric. The old part of the city was largely destroyed by air attack in 1940.

Other centres of *arrondissements* are Clermont, Compiègne and Senlis (*qq.v.*). The *département* comes under the court of appeal at Amiens and for educational administration is under the *académie* of Paris. (AR. E. S.)

OISE RIVER, of northern France, 188 mi. long, flows from the Belgian frontier southwest to join the Seine at Conflans, 40 mi. below Paris. Rising in Belgium on the western flank of the Ardennes at a height of nearly 1,000 ft., the Oise enters France within 10 mi. of its source and traverses the impervious clay country of Thiérache, now a district of intensive dairy farming. There it collects numerous small headwaters and its important left-bank tributary, the Serre. Below Guise it follows a braided course in its flat, alluvial valley, and enters the northern part of the Tertiary limestone platform of the Île-de-France. It flows through well-wooded country, its valley being flanked by the forests of St. Gobain, Compiègne, Senlis and Chantilly, which occupy extensive patches of residual sands overlying the limestones. Above Compiègne it receives its main tributary, the Aisne, from the east and, below the industrial town of Creil, the Thérain from the northwest. It approaches the Seine past Pontoise in a trenchlike valley that separates Vexin from the Île-de-France.

The Oise is an important link in the canal system between the navigable waterways of the Seine system, focusing upon Paris, and the heavily industrialized districts of northeast France and Belgium. (AR. E. S.)

ŌITA, Japanese prefecture (*ken*) of northeastern Kyushu. Area 2,437 sq.mi.; pop. (1960) 1,239,655. Its interior is dominated by complex mountainous terrain, and most human activity centres on small coastal plains. The long, irregular coastline is marked by deep-cut Beppu bay and the rounded Kuni-zaki peninsula. Most Ōita inhabitants are farmers who raise subsistence and some cash (tobacco, reeds, citrus fruit and cattle) commodities. Forestry (bamboo and cryptomeria) flourishes in the mountains. A little industry is found in the main coastal cities (cotton textiles, metals, cement and chemicals). Beppu is among Japan's most famous hot spring resorts.

ŌITA, the prefectural capital and largest (pop. [1960] 124,807) city is located on the southern coast of Beppu bay. It reached its greatest fame in the 16th century but declined in the Tokugawa period. It is mainly an administrative, commercial and educational centre, with few industrial establishments. (J. D. EE.)

OJIBWA, an ethnic group of American Indians speaking an Algonkian language, now found widely dispersed in both Canada and the United States. When first reported in the *Jesuit Relations* (1640), they occupied a comparatively restricted region near the St. Mary's river and in the upper peninsula of Michigan, but moved west as the fur trade expanded. They fought the Dakota with firearms obtained from the French, driving them from Mille Lacs and occupying the northern part of Minnesota. In Canada some Ojibwa penetrated beyond the woodlands and reached the country west of Lake Winnipeg, where they were influenced by the manner of life found in the prairie tribes. Called Saulteurs by the French traders, they continue to be called by the name Saulteaux in Canada. The meaning of the name Ojibwa, usually rendered "to roast until puckered up," refers to the puckered seam characteristic of their moccasins. The appellation Chippewa was officially adopted in the publications of the Bureau of American Ethnology, and actually is a corruption of Ojibwa.

In the United States the Ojibwa constitute one of the largest remnants of the aboriginal population. During the period of the 1960s the U.S. department of the interior reported Chippewa on reservations in the states of Michigan, Minnesota, Montana, North Dakota and Wisconsin. Altogether, they probably numbered more than 30,000, possibly 80% of them being of mixed blood. In Canada there were approximately 20,000 Ojibwa, although the number of their reservations in the provinces of Ontario, Manitoba and Saskatchewan outnumber those in the U.S. five to one. (*See* ALGONKIAN TRIBES; INDIAN, NORTH AMERICAN.)

Originally forest dwellers, hunters and gatherers of wild rice, the Ojibwa have made varying social adjustments to the contemporary world just as they did in their historic past to the different circumstances in which they found themselves. At no time have they been a politically unified nation, their traditional social organization being adapted to group living in small local bands. Because of the great popularity of Longfellow's *The Song of Hiawatha* (1855), based on Henry R. Schoolcraft's study of

Ojibwa mythology while living at Sault Ste. Marie, Mich., in the early 19th century, the Ojibwa have achieved a romantic fame in literature, unique among the peoples of North America.

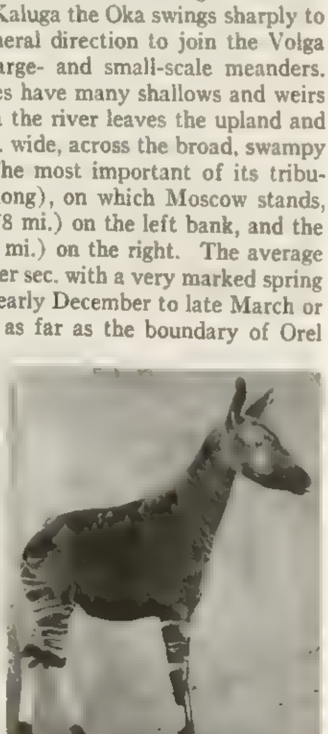
See H. Hickerson, *The Southwestern Chippewa* (1962); E. S. Rogers, "Changing Settlement Patterns of the Cree-Ojibwa of Northern Ontario," with bibliography, *Southwestern Journal of Anthropology*, vol. 19 (spring 1963). (A. I. H.)

O.K., a colloquial expression, also written okay, used to indicate approval, is probably more widely understood than any other word or phrase in any language. It originated in the United States, but for a full century, despite the popularity and almost universal use of the term, its origin remained obscure. From 1840, which most authorities accepted as the date of its first appearance in print, the term moved rapidly into the everyday language of all the English-speaking peoples. During World War I it became widely known in Europe, at least on the level of vernacular, and in World War II it was carried by U.S. and British troops into practically every part of the world.

Until the 1940s there were many theories about the origin of O.K. One of the most popular ideas was that it originated in the Choctaw word *oke,* a term of approval; several dictionaries used this derivation, qualified with "probably." Another popular theory held that the initials represented *oll korrect,* this gross misspelling being attributed to both John Jacob Astor and Andrew Jackson.

The disputes over the origin of O.K. apparently were ended in 1941 when Allen Walker Read showed that the term derived from the Democratic O.K. club, a political group in New York city supporting Martin Van Buren for the presidency in 1840. The initials came from "Old Kinderhook," a nickname for Van Buren derived from the name of the New York village where he was born. From this beginning as a political rallying cry, O.K. quickly took its place in the language.

OKA, a river in central European Russian Soviet Federated Socialist Republic, U.S.S.R., and the largest right-bank tributary of the Volga, is 919 mi. long and drains a basin of 94,595 sq.mi. It rises in the Central Russian upland (Sredne-Russkaya Vozvyshennost) and flows north in a fairly narrow and winding entrenched valley past Orel and Kaluga. At Kaluga the Oka swings sharply to the east and continues in this general direction to join the Volga at Gorki, although with many large- and small-scale meanders. Both the upper and middle courses have many shallows and weirs have been built. Beyond Kashira the river leaves the upland and flows, in a flood plain about 12 mi. wide, across the broad, swampy depression of the Meshchera. The most important of its tributaries are the Moskva (312 mi. long), on which Moscow stands, Klyazma (402 mi.) and Ugra (278 mi.) on the left bank, and the Moksha (433 mi.) and Upa (210 mi.) on the right. The average annual discharge is 43,437 cu.ft. per sec. with a very marked spring maximum. Freeze-up lasts from early December to late March or early April. Navigation extends as far as the boundary of Orel *oblast* and the river is an important artery for grain and lumber.



W. SUSCHITZKY

OKAPI (OKAPIA JOHNSTONI)

Another Oka river rises in the Eastern Sayan mountains (Buryat Autonomous Soviet Socialist Republic) and flows for about 600 mi. past Zima to join the Angara river at Bratsk in Irkutsk *oblast.* (R. A. F.)

OKAPI (*Okapia johnstoni*), a large cud-chewing mammal allied to, but smaller than, the giraffe, inhabiting the Semliki forest of the Congo. It was unknown to science until 1900. The neck and legs are shorter than those of the giraffe and the shoulder height of females, which are larger than males, is a little more than five feet. The body is plum coloured, the sides of the face dull reddish, the upper parts of the legs irregularly barred with black and white, and the shanks white with black fetlock rings. The ears are large and the horns, confined to males, are short and covered with skin, except at the tips.

The okapi is a shy, nocturnal animal that lives singly or in pairs; it browses on leaves in the dense forest, where its only enemies appear to be the pygmy hunters. Living okapis have been exhibited in many zoological gardens and have been successfully bred in captivity. The female comes into heat approximately every 40 days. The young, born after a gestation period of about 425 days, is nursed by the mother for three to four months. See also RUMINANT. (L. H. M.)

OKAYAMA, Japanese prefecture (*ken*) of western Honshu, bordering the Inland sea. Area 2,726 sq.mi.; pop. (1960) 1,670,454. It has a predominantly agricultural economy, and rice, grapes, peaches, rush (for matting) and other cash crops are grown in the southern districts. Farm techniques and the degree of mechanization are among the most advanced in Japan. Life in the interior mountains is poor and largely dependent upon forestry and small-scale cattle raising. Steadily increasing manufacturing is concentrated in such southern cities as Okayama, Kurashiki (synthetic fibres) and Tamanoi (shipbuilding). Salt fields, used to extract salt from sea water, line the seacoast.

OKAYAMA city, the prefectural capital (pop. [1960] 260,773) is located in the central Okayama plain astride the Asahi river. An old castle town of the Ikeda clan, it dominates prefectural life. A major marketing centre, Okayama has excellent rail connections with cities on the Inland sea, Sea of Japan and Shikoku (via ferry). Since its river port is shallow, it uses Tamanoi as its outport. Industry includes the manufacture of agricultural machinery, cotton and man-made textiles, and rubber goods.

Okayama university is noted for its medical college. Kōrakuen, laid out in 1786, is one of Japan's three most celebrated public gardens. (J. D. E.)

OKAZAKI, a textile-manufacturing city and commercial centre of the west Mikawa plain, central Honshu, Japan. Pop. (1960) 166,095. The town developed around Okazaki castle after its construction in 1455. During the Tokugawa period (1600–1876) it prospered as one of the 53 stage towns on the Tokaido (Tokyo-Osaka) route. Okazaki refused to allow the Tokaido railway to pass through the city in 1888.

For some years the town declined. Later it was connected with Nagoya and Toyohashi by rapid-transit lines and its economy was revived. In the 1960s there were about 300 small spinning mills and 3 large, modern textile plants; other factories produced foods, machinery, chemicals and fabricated metals. (R. B. H.)

OKEECHOBEE, LAKE, the second largest fresh-water lake wholly within the United States, is located 40 mi. W.N.W. of Palm Beach, Fla. Bearing the Seminole Indian word for "big water," it has a shoreline of 135 mi., a length of 35 mi. and including three small islands covers an area of 700 sq.mi. The surface is 12.5 to 15.5 ft. above mean sea level depending upon the water supply; the mean depth is 7 ft. and the maximum depth 15 ft.

The chief source is the Kissimmee valley watershed, immediately to the north, which drains into a chain of lakes that in turn empties into the Kissimmee river as it flows southward almost 100 mi. to Lake Okeechobee. Before the construction of adequate levees and a regulatory outlet system, the overflow produced by the rainy season flooded surrounding areas and spilled over southward into the Everglades (*see* EVERGLADES).

First plans for drainage were made in 1881 when Hamilton Disston of Philadelphia purchased from the state 4,000,000 ac., much of it in the Lake Okeechobee area, which he contracted to reclaim. His death in 1896 halted the operations. In 1904 Napoleon B. Broward won the governorship on a spectacular platform of draining the Everglades. Begun by Broward, this undertaking was continued until Sept. 1928, when hurricane winds flooded the area. Subsequently the federal government aided the reclamation project. A levee 85 mi. long was constructed along the southern shore and at other low stretches; its height varies but averages about 34 ft., approximately 20 ft. above the usual lake level. Pumping stations, spillways, hurricane gates and locks also were provided.

In 1937 a 155-mi. cross-state waterway from Stuart on the Atlantic ocean across Lake Okeechobee through the Caloosahatchee river to the Gulf of Mexico was completed. Lake communities include Pahokee, Belle Glade, Lake Harbor, Clewiston, Okeechobee and Canal Point. A Seminole Indian reservation is located on the northwest shore of the lake. The Lake Okeechobee region is also a part of the Central and Southern Florida Flood Control district. Further improvements to the Lake Okeechobee levee system and to its regulatory outlet works are included in the project. (A. J. H.)

OKEFENOKEE (OKEFINOKEE), a famous U.S. primitive swamp and natural wildlife refuge of southeastern Georgia and northern Florida, is a shallow, saucer-shaped depression approximately 20 mi. wide and 40 mi. long, covering about 600 sq.mi. The swamp is about 60 mi. inland from the Atlantic coast in Brantley, Clinch, Ware and Charlton counties in southeastern Georgia, and Columbia and Baker counties in northern Florida. Low, sandy Trail Ridge forms the eastern swamp boundary and prevents drainage toward the Atlantic. The swamp is partially drained by the Suwannee and St. Marys rivers. Included are low, sandy ridges, wet, grassy savannas, small islands called "hummocks" surrounded by marshes, and extensive "prairies" or dark-water areas covered by thick undergrowth and trees. Narrow channels of open water are interlaced among hummocks, prairies and wet savannas to form a bewildering maze. Vegetation is dense in the swamp. There are giant tupelo and cypress trees festooned with Spanish moss, brush and vines; where sandy soil is above the water, pines predominate. Exotic flowers abound, including floating hearts, lilies and rare orchids. The swamp is populated with deer, bear, raccoons, alligators, snakes and many varieties of fish, turtles and lizards. There are at least 200 different species of birds, including the ibises.

In 1937, 331,900 ac.—including most of the swamp in southeastern Georgia—were set aside as the Okefenokee National Wildlife refuge. The entrance to the refuge is at Waycross, Ga. Boat tours, trestle walks and alligator-hunting boat excursions are among the tourist attractions. (M. C. P.)

OKEGHEM, JEAN D' (JOHANNES) (*c.* 1420–*c.* 1495), Flemish composer and singer, known for his church music and chansons. His earliest recorded appointment was as a singer at Antwerp cathedral from 1443 to 1444. He served in a similar capacity in the chapel of Duke Charles of Bourbon from 1446 to 1448 and at a later date in the royal chapel. He acted as chaplain and composer to three successive kings of France (Charles VII, Louis XI and Charles VIII) and by 1465 was given the title of *maître de la chapelle du roy*. As treasurer of the wealthy abbey of St. Martin at Tours, he was the recipient of a handsome salary which became the object of a pun by Erasmus, who referred to the *aurea vox Okegi* (the golden voice of Okeghem). He died at Tours about 1495.

Like many of his Flemish contemporaries, Okeghem was a great traveler and made the maximum use of his visits to distant cities to improve his musical knowledge. He knew Gilles Binchois of Burgundy and mourned his death in a lament of touching beauty; in turn he received during his lifetime the musical tributes of A. Busnois and L. Compère, and after his death the moving *Déploration* of Josquin Després.

Okeghem was a follower of Guillaume Dufay and John Dunstable, and, if his mature work sounds richer than theirs, it is because instrumentally supported vocal lines were being gradually modified so as to make way for sonorous choral harmony, and not because he invented (as is sometimes claimed) a polyphonic texture knit together by constant melodic imitation. There is hardly any imitation in his magnificently austere *Missa pro defunctis* and only the slightest trace of canon, a device of which he was supreme master.

His ten motets include favourite Marian texts such as *Ave Maria*, *Salve regina* and *Alma redemptoris mater*, as well as a complete setting of the responsory *Gaude Maria*. Fourteen Masses have survived, but two consist of Kyrie, Gloria and Credo only, while another has only the first two sections. He often uses pre-existent material, as in the Masses based on chansons: "Fors seulement," "De plus en plus" and "Au travail suis." The *Missa prolationum* and the *Missa cuiusvis toni* are both, in different ways, examples of Okeghem's highly developed contrapuntal and canonic technique. There are also about 20 chansons. Two volumes of a complete edition of Okeghem's works, edited by Dragan Plamenac, were published by the American Musicological society (1947 and 1959). (D. W. ST.)

O'KELLY (Irish O CEALLAIGH), **SEAN THOMAS** (1882–1966), Irish statesman, one of the founders of Sinn Fein, president of Ireland from 1945 to 1959. He was born in Dublin on Aug. 25, 1882. His education was partly private, partly at the O'Connell schools, Dublin. Later he was for some years an assistant in the National Library of Ireland. He became associated with Arthur Griffith (*q.v.*) in the editing of various Irish journals in 1905, and acted as honorary secretary of Sinn Fein from 1908 to 1910. He was also a formative influence in the Gaelic league, of which he was general secretary (1915–20). From 1913 onward he was active in raising the Irish Volunteers and, during the Easter rising of 1916, fought as a staff captain in the general post office, Dublin. On the collapse of the rising, he was imprisoned until the following year.

In the Sinn Fein election of 1918 which swept away the old Irish Nationalist party, he was returned for College Green division (Mid-Dublin), Dublin city, and was subsequently elected speaker of *dáil éireann*. From 1918 to 1945 he represented at intervals various divisions of Dublin in *dáil éireann*. In 1919 he was accredited by the *dáil* to the peace conference in Paris as envoy of the government of the Irish republic; later he acted in the same capacity at Rome and Washington. In June 1945 he was elected president of Ireland for a term of seven years; and in May 1952 was re-elected unopposed for a further term of seven years—his unopposed return being a tribute of affection and respect from the Irish people. On the conclusion of his second term of office (June 1959) he withdrew from public life. He died in Dublin on Nov. 23, 1966. (D. L. I.)

OKEN, LORENZ (1779–1851), German naturalist, whose real name was OCKENFUSS, is remembered not only for his several solid achievements in the advancement of biology but also for his participation in the abortive physio-philosophical movement called *Naturphilosophie* in Germany in the early 19th century. He was born at Bohlsbach, Baden, on Aug. 1, 1779. He studied at Würzburg and Göttingen, where he became *Privatdozent*, and in 1807 was appointed professor extraordinarius of medical sciences at Jena. His inaugural discourse on the signification of the bones of the skull, based upon a discovery he had made in the previous year, was delivered in the presence of Goethe, as privy councilor and rector of the university, and was published in the same year.

In 1816, at Weimar, he began to publish the periodical *Isis*, but comments on politics led to his removal from Weimar. He continued to publish the *Isis* at Rudolstadt until 1848. In 1821 Oken promulgated the idea of annual general meetings of German naturalists and medical practitioners, the first meeting being held in Leipzig in 1822. After teaching at the University of Munich (1828–32), he transferred to the professorship of natural history at the University of Zürich, where he served until his death, in Zürich, Aug. 11, 1851.

Oken's writings display his philosophical kinship with Kant and Schelling and bare his reliance on deductive logic. For example, he theorized that the head was a repetition of the trunk—a kind of second trunk, with limbs and other appendages. A priori postulates of this kind prevented his making any real contributions to the science of comparative anatomy. (K. P. S.; X.)

OKHOTSK, SEA OF, a part of the northwestern Pacific ocean, bounded east by the Kamchatka peninsula and the Kuril Islands, south by Hokkaido, Jap., and west by the island of Sakhalin and the shore of continental Asia from the Amur estuary to the mouth of the Penzhina river. Area 613,838 sq.mi. and maximum depth 11,069 ft. The northern part has a continental climate with an average annual temperature of −5° to −6.7° C. (23° to 20° F.); in January and February, the coldest months, the temperature averages −22.6° to −23.7° C. (−9° to −11° F.).

Ice forms in late October or early November and much of the sea is covered by March, the ice limit running from southern Sakhalin to southern Kamchatka. In April the ice breaks up and usually disappears by June, except for the Gulf of Sakhalin, where it may linger until August. The influx of waters from the Pacific, especially between the eastern and central Kurils, forms a powerful north-flowing current in several branches in the east, while in the west a similar south-flowing current is supplemented by drainage from the mainland. The sea is linked with the Sea of Japan by the Tatar and Sōya straits. Magadan on the northern shore and Korsakov (formerly Otomari) on south Sakhalin are the chief ports. The fisheries provide about one-tenth of the total catch of the U.S.S.R., mainly salmon, and also herring and crab; the catch is canned in factory ships. (R. E. F. S.)

OKI-GUNTŌ, a group of Japanese islands, lying in the Sea of Japan due north of the Honshu prefecture of Shimane, of which they form a part, 36° N. and 133° E. The group consists of one large island, called Dōgo, and three smaller isles—Chiburi-shima, Nishino-shima, and Nakano-shima—which are collectively known as Dozen. These four islands have a coastline of 223 mi., an area of 134 sq.mi., and a pop. (1960) of 41,639. The chief town is Saigō on the island of Dōgo, about 40 mi. distant from the port of Sakai in Shimane.

The region is celebrated in Japanese history not only because the possession of the islands was much disputed in feudal days but also because a former emperor and an emperor were banished there by the Hōjō regents in the 13th century.

OKINAWA, a pre-World War II Japanese prefecture, is composed of the island groups (Nansei-Shotō in Japanese; Ryukyu Islands in English) stretching from Japan to Formosa. The Ryukyus came under U.S. control by the 1951 Japanese peace treaty; Japan kept residual sovereignty. The northern island groups, Ōsumi, Tokara and Amami, reverted to Japan by 1954. The southern groups, the Okinawa and the Sakishima islands, remained under U.S. control. Three-fourths of the inhabitants are farmers or fishermen. Sweet potatoes and sugar cane are the main crops. The islands suffer from chronic overcrowding. The largest (454 sq.mi.) island, Okinawa (pop. [1960] 698,590), has 80% of the Ryukyu population, as well as some of the largest U.S. military bases in the western Pacific. Its principal city, Naha, once the capital of the Japanese Okinawa prefecture, is the seat of the U.S. military government and the native Ryukyu government, a 29-member legislature with a chief executive appointed by U.S. authorities. For the battle of Okinawa, *see* WORLD WAR II: *The War in the Pacific.* (J. D. EE.)

OKLAHOMA, popularly called the "Sooner state," is a west south-central state of the United States, admitted to the union in 1907 as the 46th state. It is bounded on the north by Colorado and Kansas, on the east by Missouri and Arkansas, on the south and west by Texas and on the far west (panhandle) by New Mexico. The area is 69,919 sq.mi., including more than 1,000 sq.mi. of water surface (artificial lakes and ponds); it ranks 18th among the states in size. The capital is Oklahoma City, located in the centre of the state. The name Oklahoma, a Choctaw Indian term meaning "red people," was first applied to the Indian Territory in 1866. The popular name "Sooner state" was derived from the term "sooner," referring to a person who entered and staked a claim for land sooner than the law stipulated when the central part of the Indian Territory was opened to homesteading in 1889. The Oklahoma state motto is *Labor omnia vincit* ("Labour Conquers All Things"). The flag has a blue field on which is a circular rawhide shield, superimposed on the face of which is a peace pipe crossed by an olive branch. The state floral emblem is the mistletoe, the tree the redbud, the bird the scissor-tailed flycatcher, the song "Oklahoma" (from the musical *Oklahoma!*).

PHYSICAL GEOGRAPHY

Physical Features.—The topographical features of Oklahoma (between approximately 33° 38′ and 37° N. lat. and 94° 26′ and 103° W. long.) range from wide treeless plains in the west to rugged, heavily wooded mountains in the east. The altitude varies from 4,978 ft. above sea level on the summit of the Black Mesa, a volcanic tableland 700 ft. above the valley floor of the Cimarron river, in the northwestern corner of the panhandle, to 350 ft. above sea level on the bank of the Red river in the southeastern corner of the state.

There are four mountain regions in the eastern and southern parts of Oklahoma. The western fringe of the Ozark mountains (*q.v.*) in the northeast extends nearly halfway across the state in a chain of low sandstone hills gradually decreasing in height westward. These hills include such well-known features as Claremore mound, Concharty hills, Council hill and Shawnee hills. The Ouachita range, crossing the eastern boundary, lies in southeastern Oklahoma; in this region, noted for its scenic beauty, are mountains of appreciable heights, the highest being Rich mountain, 2,950 ft. above sea level, in Le Flore county. The Arbuckle mountains in the south-central part of the state have summits of moderate altitude. Between the valleys of the Red and Washita rivers west of the 98th meridian are the Wichita mountains, in which, among several well-known peaks, are Mt. Scott (2,464 ft.), Mt. Sheridan and Saddle mountain.

The plains region of western Oklahoma has widely distributed gypsum deposits, and many parts of the area are characterized by deeply eroded streams, fantastically weathered outcrops and bold hills. The Glass mountains located near the Cimarron river in Major county are typical of gypsum scenery. A striking feature in the northwest is the Big Salt plain in Woodward county, one of four such plains; it is almost level, varying in width from ½ mi. to 2 mi. and extending 8 mi. along the Cimarron river.

Following the general slope of the land, most of the important streams flow from northwest to southeast. The Arkansas river enters the state near the 97th meridian, flows generally southeast and leaves near the centre of the eastern boundary. Its tributaries from the north and east are small but important streams—Verdigris, Grand (or Neosho) and Illinois; from the west it receives much larger streams—Salt Fork, Cimarron and the Canadian with its numerous tributaries. The southern part of the state is drained by the Red river and its tributaries, the North Fork, Washita, Blue, Boggy and Kiamichi. Another important stream in the southeast, with its tributaries the Mountain Fork and other clear-flowing creeks, is Little river which empties into Red river east of the Oklahoma boundary, in Arkansas.

Climate.—The climate of Oklahoma is continental, with wide variations of temperature and humidity. The western and central parts are generally cooler and drier than the eastern section. At Boise City, in the northwest, the average annual daily temperature is about 55° F. (about 13° C.) and the annual rainfall is 16.51 in.; while at Idabel, in the southeast, the average annual daily temperature is about 63° F. and the annual rainfall is 46.53 in. At Oklahoma City in the centre of the state the average annual daily temperature is 60° F. and the average annual rainfall is 30.22 in. The highest temperature recorded in the state was 120° F. (about 49° C.) in the summer of 1936, in widely separated places; the lowest temperature recorded was −27° F. (−33° C.) at Vinita in 1905.

Soil.—The greater part of the soil in Oklahoma is residual, partaking of the character of the rocks from which it was derived, found in a number of soil areas that in general correspond to the topography of the region. The most fertile is the black limestone soil found in abundance in the Ozark and especially the Arbuckle mountain regions, where the Arbuckle limestone lies 6,000–8,000 ft. thick, one of the heaviest limestone ledges in the world. A stiff clay soil is found in the east where clay and shale characterize the surface rocks of the great coal fields that lie north and south of the Ouachita range. In the central part of the state and its adjoining sections, the soil is highly fertile and of a deep red colour derived from the brick-red shales and clays of the rocks known as red beds.

Vegetation.—Eastern Oklahoma was originally covered with forest growth, with small prairie areas interspersed. Since it is well within the humid region, vegetation is practically identical with that of other states of the central and lower Mississippi valley. Principal trees in this eastern section of the state are several species of oak and hickory (including the pecan), besides walnut,

elm, sycamore, gum, ash bois d'arc (or Osage orange), red cedar, pine, cypress and many others. In the central part of the state timber growth is generally limited to narrow fringing belts of a few species of trees along the streams—elm, cottonwood, hackberry, chinaberry, hickory and walnut. Blackjack, post oak and hackberry and hickory grow in the sand-hills region. The distribution of trees is even more limited in the western part of the state, where the thorny mesquite is found along some of the streams and flat prairies. In this semiarid western region, dwarf species of oak, walnut and hackberry are sometimes found.

Wild fruits and berries include plum, crab apple, cherry, blackberry, dewberry, raspberry, gooseberry, currant, grape, strawberry, huckleberry, persimmon, papaw and others.

There are many species of native grasses in Oklahoma. Grasses grow tall in the eastern and central parts of the state, bunch grass being commonest. Bluestem is scattered widely throughout the prairies. Western Oklahoma was often called the short grass country, for there were found the dwarfish, low-lying buffalo, mesquite and grama grasses. Buffalo grass was the commonest native grass in this semiarid region, furnishing excellent pasturage under all range conditions, summer and winter, growing low and thick and forming a heavy sod carpet on the ground.

Animal Life.—Oklahoma was once a great hunting ground. Buffalo were originally found in all parts of the state, and enormous herds roamed over the western plains until a comparatively late date in history. Other important species of animals that were plentiful in the region included elk, deer, antelope, bear, panther or cougar, wildcat, timber wolf, coyote, fox, beaver, otter, muskrat, mink, squirrel, badger, skunk, raccoon, opossum, jack rabbit and prairie dog.

A very large number of birds, resident and migratory, have been found in Oklahoma. The country teemed with wild turkey, prairie chicken and bobwhite quail. Great flocks of the now-extinct passenger pigeon and the Carolina parakeet once were found in this region. Hawks and turkey buzzards are the commonest types of large birds; smaller birds include the mockingbird, robin, meadow lark and cardinal.

The Wichita Mountains Wild Life refuge, established in 1902 as a national preserve of 58,000 ac., is noted for fine herds of buffalo, elk and the now rare Texas longhorn cattle. The state game and fish commission supervises a number of smaller game preserves over the state, for deer, turkey and quail. The commission in 1930 established the Great Salt Plains Wild Life Refuge in Alfalfa county, where a large salt lake reservoir is a sanctuary for migratory waterfowl.

Parks and Recreation.—The construction of large lakes along streams in the U.S. flood control program and the establishment of state parks in Oklahoma brought great changes in living conditions in the surrounding areas after 1930, with millions of visitors coming to the state annually for fishing and water sports. The largest artificial lakes are Lake Eufaula, its several arms extending a distance of more than 130 mi. along the Canadian river and its tributary streams in McIntosh, Pittsburg and Haskell counties; Lake Texoma extending more than 100 mi. along the Red and the Washita rivers; Lake O' The Cherokees, more than 65 mi. along the Neosho river; Fort Gibson lake, more than 40 mi. along the Arkansas and the Cimarron rivers; and Lake Ten Killer, more than 25 mi. along the Illinois.

Oklahoma state parks in scenic or historic areas include Alabaster Caverns and Boiling Springs, in Woodward county; Beavers Bend park, a primitive forest area, McCurtain county; Greenleaf Lake park, southeast of Muskogee; Lake Murray park, near Ardmore in the old Chickasaw Nation; Osage Hills park in Osage county, this county comprising the former Osage Indian reservation; Robbers Cave park, Latimer county; Quartz Mountain park at Lake Altus on the north fork of the Red river; Roman Nose park, named for a noted Cheyenne chief, Blaine county; Sequoyah park on Fort Gibson reservoir east of Wagoner; Lake Wister park, Le Flore county; Lake Clayton Recreation Area in the Kiamichi mountains, Pushmataha county; Boggy Depot Memorial park, Atoka county, site of historic town (1837) in the old Choctaw Nation, once its capital and a main stop on the first U.S. Overland Mail stage route between St. Louis and San Francisco (1858). National historic landmarks include Fort Gibson (1824) stockade restoration, Cherokee county; Fort Washita (1842) 80 ac., restoration and ruins, Bryan county; and Custer Battle (1868) site, Roger Mills county. The Ouachita National forest, Le Flore county, is noted for the Choctaw Skyline drive, a scenic highway 50 mi. along the top of the Winding Stair mountains. Platt National park, Murray county, famous for medicinal springs, comprises an area ceded to the United States out of Choctaw and Chickasaw tribally owned lands in 1902.

The Oklahoma Historical society, in Oklahoma City, maintains museum and library collections of original artifacts, relicts, documents and rare books relating to both history and prehistory of the state. The last log-cabin home (1843) of Sequoyah, famous as the creator of the Cherokee alphabet, is a historic shrine in Sequoyah county. Museums of history in the state include Gilcrease Institute of Art and History, Tulsa; Stovall museum, Norman; U.S. Artillery and Missile centre, Fort Sill; Wooleroc museum, Bartlesville; Cowboy Hall of Fame and Western Heritage center, Oklahoma City; Will Rogers Memorial museum, Claremore; Panhandle Historical museum, Goodwell; the American Indian Hall of Fame and the Indian city, both in Anadarko; Five Civilized Tribes museum, Muskogee; and Great Plains museum, Lawton.

HISTORY

Prehistory.—Archaeological excavations have brought to light evidences of human occupancy within the boundaries of the state more than 10,000 years ago. The steep banks of some streams in the Ozark hills in the northeast and in the Panhandle northwest furnished rock ledges and caves for the dwelling places of ancient peoples. Hard rock formations, especially flint, furnished spear points for hunting. Stone spear points, probably those of Clovis man, known to have lived earlier than Folsom man, were found near the skeleton of a mammoth excavated in Caddo county. Excavation of the floors of caves in the western part of the Panhandle has brought up the utensils of an agricultural people of 4,000 years ago. Some of their basketry, small bags of skin for holding seeds and fur lined moccasins were found, as well as stone scrapers and knives and wooden drills for starting fire. Pieces of crude pottery, kernels of corn and corn cobs, bone fishhooks and implements of animal bones and deer antlers used for growing corn have been found in the Ozark caves. Spiro mound, of about A.D. 850, near the town of Spiro in Le Flore county, has yielded spectacular evidence of the culture of an ancient people that built this great temple mound and other mounds in the vicinity. A long list of articles taken from the temple mound includes huge ceremonial pipes of stone carved in human and animal effigies; smaller clay and stone pipes; fine pottery molded in art forms; cedar masks and basketry; woven materials of buffalo hair, furs and feathers; polished stone implements; shell gorgets etched with ancient designs; pearl and stone beads; and large conch shells with etchings that show the life of the people of the mounds. An eagle design on copper plate, copper axes and copper covered ear-spools give evidence that the use of metal was known.

The Indian Territory.—The Spanish expedition led by Francisco Vázquez de Coronado in his exploration of the Great Plains in 1541 followed a direct route southwest across the Oklahoma panhandle. Three centuries later this route approximated that of the Santa Fe trail (*q.v.*), traces of which are visible in Cimarron county. Oklahoma, a part of Louisiana, was under the influence of the French during the 18th century, and many French names of mountains and streams dating from that period may be seen on maps of the state.

Oklahoma east of the 100th meridian became known as the Indian Territory after the act of congress of May 28, 1830, which provided for removal of the Indian tribes living east of the Mississippi river to lands in the west. Five large tribes, later known as the Five Civilized Tribes—Choctaw, Creek (or Muskogean), Seminole, Cherokee and Chickasaw (*qq.v.*)—were removed from the southeastern states to the Indian Territory (1830–42), where

they settled on large tracts owned by them under patents from the government, as provided in different treaties from 1820 to 1837. These tribes established their own governments as nations, with written laws, courts of justice and elected officers. They maintained schools and fostered churches, missions and printing presses for newspapers and books in the native languages. The five Indian capitals and dates of establishment, at some of which old buildings stand, were Nanih Wayah (1834), Choctaw Nation, site 2 mi. from the last capitol building, near Tuskahoma (in present Pushmataha county); Tahlequah (1839), Cherokee Nation (in present Cherokee county); Tishomingo (1856), Chickasaw Nation (in present Johnston county); Okmulgee (1867), Creek Nation (in present Okmulgee county); and Wewoka (1869), Seminole Nation, this tract comprising Seminole county in the state.

American Civil War.—The people of the Indian nations and their governments were southern in their background and institutions. Some of the Indian leaders were wealthy owners of Negro slaves and plantation properties in the valleys of the Arkansas and Red rivers. But while there was strong feeling for the South and the seceding states, especially in the Choctaw Nation, there also was widespread sentiment for neutrality and staying out of the "white man's war" under such leaders as Chief John Ross of the Cherokee Nation and the venerable Opothleyahola of the Creek Nation. The United States had guaranteed the Indian nations military protection against their enemies; however, at the outbreak of the Civil War all U.S. troops were withdrawn from the Indian Territory to Kansas, leaving the ungarrisoned posts open to occupation by Confederate troops from Texas and Arkansas. By Oct. 1861 Albert Pike, appointed commissioner at Richmond, Va., had concluded treaties of alliance between the Five Civilized Tribes and the Confederate states; similar treaties also had been made with other tribal groups in the Indian Territory. During the summer and autumn of 1861, the Indian nations organized their forces for military service in the Confederate army.

Division among the Indian peoples in their sympathies between the northern and southern states began in the Creek Nation under the leadership of Opothleyahola, who refused to recognize the Confederate-Creek treaty. Setting out with about 5,000 followers for the wild country in the Cherokee outlet east of the Arkansas river, he was followed and attacked three times by Confederate troops (white and Indian). His forces were defeated in the third fight (battle of Chustenahlah, Dec. 26, 1861), and his followers, including some Seminoles, fled destitute in a winter storm to Kansas, where they became refugees within the Union lines. Confederate Indians from several other tribes soon went over to the Union side and were organized in Kansas as Indian home guard regiments in the U.S. army. Federal forces entered the Indian Territory and took over Ft. Gibson late in 1862, this post remaining the stronghold of the Federals until the end of the War.

Ft. Washita with its outpost and commissary at Boggy Depot was the Confederate stronghold. Troops and scouting parties of both armies swept back and forth across the county in the Arkansas River valley from Fort Smith west and north to the Kansas and Missouri lines. There were many engagements and skirmishes and countless "brush" fights. The major battle in the Indian Territory was fought at Honey Springs (in present McIntosh county) on July 17, 1863, when 3,000 Federal troops under the command of Maj. Gen. James G. Blunt forced the retreat of Brig. Gen. D. H. Cooper's Confederate forces. The outstanding Confederate victory was the capture of a Federal wagon train worth more than $1,500,000, in the second Battle of Cabin Creek (in present Mayes county) on Sept. 19, 1864, by Confederate troops under the command of Brig. Gen. Stand Watie of the Indian brigade and Brig. Gen. R. M. Gano of the Texas brigade. The war was one of attrition in the Indian nations, leaving the people impoverished and their institutions wrecked. The Cherokee country, the Creek and the Quapaw northeast were scenes of desolation. While many Confederate Indian officers were cited for bravery and gallantry in action during the War, only the Cherokee leader Stand Watie attained the rank of brigadier general. He was the last general officer of the Confederacy to surrender at Doaksville, Choctaw Nation, on June 23, 1865.

Postwar Period.—New treaties with the Five Civilized Tribes, demanded by the federal government, were signed at Washington in 1866. While each of these dealt with local conditions and problems as a result of the war there were some general provisions common to all: the abolition of slavery; rights of way granted for the building of two railroads (one north to south and one east to west); plans for the organization of the territory as a federal commonwealth with a legislative body composed of delegates from each of the Indian nations and tribes within its borders; and the cession of the western tribal lands (western Indian Territory) to the United States, this provision being in retaliation for the recent alignment of the tribes with the Confederate government. These land cessions, involving millions of acres, meant great changes throughout the region. The five Indian governments continued in greatly reduced areas in eastern Indian Territory, and social conditions changed from a pastoral to the beginnings of an industrial society. Towns and villages sprang up beside the railroads where settlers came to live as owners of stores and other small enterprises.

The ceded lands in western Indian Territory were assigned by the government as reservation tracts for Indian tribes brought there from many parts of the United States. The new reservations bordering the Five Civilized Tribes on the west (now central Oklahoma) were assigned to tribes from Kansas and adjoining states, including Osage, Kaw, Sac and Fox, Shawnee, Potawatomi, Ponca, Pawnee and others. Farther west in the territory were the big reservations assigned the Plains tribes—Comanche, Kiowa, Kiowa-Apache, Cheyenne, Arapaho.

During the first years, some of the leaders of the latter tribes were imbued with the spirit of the Indian wars on the Great Plains, and military campaigns were undertaken against some of the tribal bands. The last of the warring Plains tribes was the Quahadi band of Comanche under Quanah (later noted as Chief Quanah Parker), who came in from the Staked Plains of Texas and surrendered at Ft. Sill in June 1875. From this time, except for some local trouble with part of the Kiowa and the Cheyenne, the tribes of the Great Plains settled down to reservation life that continued until their lands were opened to homesteading and became a part of Oklahoma Territory.

Among several military posts established after the Civil War in western Indian Territory, Ft. Sill (1869) has been continuously garrisoned since. After World War II it became the largest artillery and missile centre in the United States.

Homesteading.—After the building (1872) of the Missouri, Kansas and Texas, the first railroad through Indian Territory, colonies of "boomers" from the states attempted to establish homesteads on a central tract (1,887,880 ac.) left unassigned for Indian reservation purposes. Boomer colonies for several years were ejected by U.S. troops because delegations of Indian leaders of the Five Civilized Tribes repeatedly went to Washington to point out that their tribal lands and properties remained in jeopardy. Until the government cleared the title of the Creek and Seminole owners of the unassigned land tract by due process of law, no patent to homestead claims could be given. Finally congress granted an appropriation to fulfill the terms of the Creek and Seminole treaties; this was followed within a few weeks by the proclamation of Pres. Benjamin Harrison opening the unassigned land to white settlement by a run for homestead claims to begin at noon on April 22, 1889. Evening of this opening day saw the unassigned land peopled by thousands who had made the run from its borders, and the tent cities of Guthrie and Oklahoma City growing. The region was without a regular system of government until the congressional act of May 2, 1890, provided the organization for the western half of the Indian Territory as Oklahoma Territory with Guthrie as the capital. The Indian Territory throughout its history was never organized under regular territorial government; the eastern half (1890–1907) remained the last Indian Territory, the land owned by the governments of the Five Civilized Tribes except for the northeast Quapaw agency region.

which was owned by several remnant tribes including Quapaw, Wyandot, Seneca and allied Indian bands. Members of all Indian tribes were allotted land in severalty, and all Indian reservations and governments were closed by 1907. Millions of acres of Indian reservation lands had been opened to white settlement and organized as part of Oklahoma territory.

Land openings were made by run into the Iowa, the Sac and Fox, and the Potawatomi-Shawnee reservations (now in five counties and parts of counties) on Sept. 22, 1891; the Cheyenne-Arapaho (now in eight counties and parts of counties) on April 19, 1892; the Pawnee, the Tonkawa and the Cherokee outlet (now in seven counties) on Sept. 16, 1893; and the Kickapoo (now in part of two counties) on May 25, 1895. The last great land opening was by "land lottery" for 160-ac. tracts in the Wichita-Caddo and Comanche-Kiowa-Apache country on Aug. 6, 1901. The Comanche-Kiowa "Big Pasture" of 500,000 ac. was sold in 160 ac. tracts to the highest bidders in 1906. The "Big Pasture" covered parts of present Comanche, Cotton and Tillman counties.

Statehood.—When congress authorized the admission of Oklahoma and Indian territories as one state, the people including the Indians voted approval of a constitutional convention (composed of 100 Democrats and 12 Republicans) which met at Guthrie on Nov. 20, 1906. The constitution framed by this body was approved by a vote of the people on Sept. 17, 1907, and the state of Oklahoma was admitted to the union by proclamation of Pres. Theodore Roosevelt on Nov. 16, 1907.

Operation of the coal mines in the McAlester and Lehigh fields had been the leading industrial development for over 30 years until the discovery of oil in 1905, in the Glenn Pool 10 mi. S. of Tulsa. The Glenn Pool touched off development of the great mid-continent field. The petroleum industry in the first 50 years of Oklahoma statehood contributed enormous revenue to the state government and its institutions. Very low prices of crude oil and waste in oil production aggravated conditions at the beginning of the nationwide depression (1933) and brought about enactment by the state legislature of the proration law of April 10, 1933, limiting production to proportional shares of capacity. This law became a pattern for other states and the federal government.

The federal government's depression emergency program was needed mostly in the eastern and southern parts of the state. It was during this period that John Steinbeck's novel *The Grapes of Wrath* popularized the term "okies," portraying poverty-stricken farm families from the Arkansas river region in eastern Oklahoma on their migration route to California.

The Oklahoma national guard, organized in territorial days, was inducted into active service in the U.S. army, as part of the 8th corps area in the 45th division (Thunderbird division), on Sept. 16, 1940, and served in the European campaigns during World War II. Soldiers from all parts of the United States were trained at Ft. Sill and approximately 28 army camps and 13 naval bases were established in different parts of the state.

One of the continuing state questions was the prohibition of the sale of liquor, which dated from 1834 when the congressional law regulating trade and intercourse throughout the Indian Territory was passed. Oklahoma Territory had been open for the sale of liquor to 1907, though the territorial enabling act (1890) had provided the continuance of prohibition for 21 years in the Indian Territory and on any Indian reservation tract. Prohibition for the new state had been voted by the people in the election of 1907. The prohibition clause finally was stricken from the state constitution by vote in the election of April 7, 1959. Under a liquor control act of the state legislature, the alcoholic control board set up state regulations for the operation of retail liquor stores.

Politics.—Oklahoma has remained consistently Democratic in politics but with a strong Republican minority, Democratic electors having been chosen in ten presidential elections and Republican electors in five; Warren G. Harding carried the state in 1920, Herbert Hoover in 1928, Dwight D. Eisenhower in 1952 and 1956 and Richard M. Nixon in 1960. All U.S. senators from Oklahoma were chosen by the Democratic party except three who won on the Republican ticket in 1920, 1924 and 1942. All governors of the state were elected on the Democratic ticket, until the election of the first Republican governor, Henry Bellmon, in 1962, and the second, Dewey F. Bartlett, in 1966. The state senate was never controlled by Republicans, and the state house of representatives had a Republican majority only in 1920.

GOVERNMENT

The Oklahoma constitution adopted in 1907 contains many provisions that in older states were left to legislation. Amendments may be submitted through a majority of the members elected to both houses of the legislature or through a petition signed by 15% of the electorate, and a proposed amendment is adopted if it receives a majority of the votes cast at a popular election. General elections are held in even-numbered years; party candidates for state, district, county and municipal offices, and U.S. senators and congressmen are chosen at primary elections.

Executive.—The executive authority of the state is divided among 12 elected officials, including the governor, lieutenant governor, secretary of state, treasurer, auditor, attorney general, superintendent of public instruction, chief mine inspector and commissioner of charities and corrections. They are elected for terms of four years. By constitutional amendment ratified in 1966 the governor may serve two consecutive four-year terms. Other elected officials are the three members of the corporation commission (one elected every two years for a six-year term), the clerk of the supreme court and four assistant mine inspectors. Administrative work is also done by more than 60 officers, commissions, departments and boards.

Legislative.—The legislature is made up of 48 senators and 99 representatives. Annual sessions were adopted (1966) beginning in 1967. One-half of the senators and all representatives are elected every two years. Apportionment of the legislature was the subject of much litigation; the 1964 election was ordered held under a stand-by measure devised by the state supreme court pending appeal before the U.S. supreme court of a plan basing districting in the senate and the house entirely on population.

Judicial.—For the administration of justice there were established a supreme court, composed of nine justices elected for terms of six years; a supreme court commission, which was discontinued after its work was completed; a criminal court of appeals composed of three justices elected (one each two years) for terms of six years; 31 district courts, each with one or more justices elected for terms of four years; superior courts in certain of the more populous counties, with a judge elected for a term of four years; a county court in each county, with one judge elected for a term of two years; and municipal courts in the cities. A district attorney system was provided by law of the state legislature in 1965.

Local Government.—The general management of county affairs is entrusted to three commissioners elected by districts. The other county officers are a sheriff, attorney, judge, clerk, court clerk, treasurer, assessor, surveyor, superintendent of public instruction and public weigher. They are chosen for terms of two years in each of the counties at the general elections.

Finances.—Revenues for state and local purposes are derived almost wholly from separate sources. The greater part of the state's revenue is derived from a gross production tax on minerals; motor vehicle licenses; insurance fees; gasoline, sales, inheritance and income taxes; and departmental collections. Revenue for local purposes is obtained chiefly from tax levies on personal and real property; there are no state levies on property, tax levies being made only by the counties, townships or cities and towns and school districts. A legislative act in 1965 enabled cities to adopt a city sales tax, with the proceeds to be used for the improvement of the city government. Oklahoma City was the first city to approve the new tax. Chief state expenditures are for highways, education, debt amortization and service and penal institutions.

POPULATION

The population of Oklahoma and Indian territories in 1890 was 258,657. A special census gave a population of 1,414,177 in the new state in 1907. The population in 1910 was 1,657,155; in

*Populations are reported as constituted at date of each census. †1900 census figures are for the Territory of Oklahoma. ‡1907 special census for Territory of Oklahoma, 1900 figures not available.
Note: Dash indicates place did not exist at reported census, or data not available.

1940, 2,336,434; in 1950, 2,233,351 (4.4% less than in 1940; and in 1960, 2,328,284 (4.3% more than in 1950).

The 1960 urban population of Oklahoma comprised 1,464,786 persons, or 62.9% of the total. The state has three standard metropolitan statistical areas, which are Lawton, Oklahoma City and Tulsa. These areas had a total population of 1,021,610 or 43.9% of the total population of the state in 1960.

The population of the state in 1960, distributed by colour was 90.5% white, including a large number of persons of American Indian descent; 6.6% Negro; 2.9% other races, mostly full-blood American Indian.

The number of households in 1960 was 734,593, as compared with 663,262 in 1950; the average population per household had declined from 3.4 in 1950 to 3.1 in 1960. Of the total number of employed 9.4% was engaged in agriculture, 4.5% in mining and oil production, 7.2% in construction, 13.2% in manufacturing and 23.1% in transportation and trade.

Oklahoma's population is cosmopolitan in its ethnic origins, with nearly every nationality represented, though the largest number of persons is of American colonial descent. The percentage of American Indians is high, persons of full blood and mixed Indian-white numbering about 400,000. The state's population of foreign descent (largely German) includes families and groups that came to Oklahoma Territory with the opening of new lands (1889–1906); another large foreign element came to the coal mining region along the railroad in eastern Indian Territory in the 1880s. The Negro population in Oklahoma increased after World War II, especially in the urban centres, but basically it consists of descendants of Negro freedmen of the Indian nations, who after the Civil War remained in the country on freedman land allotments under the terms of the treaties of 1866. Groups of Negroes came from the southern states from time to time in the period of railroad building, and others were brought to work in the mines during the coal strikes in the early 1890s. One band of Negroes migrated from southern states, chiefly Louisiana and Texas, soon after the Civil War, and located in the unassigned lands near present Guthrie, where many of their descendants still live.

The decline in the state's population figures seen in 1950 was a result principally of changes in agricultural life; costly mechanization of farming operations, necessity of soil conservation practices in many localities and the reduction of cotton acreage in cotton-growing regions caused families to leave their farms.

EDUCATION

Public Schools.—The public school system in Oklahoma is administered by the state and county superintendents of public instruction. Total annual enrollment (elementary and high schools) was approximately 500,000 in the 1960s; total expenditures were about $200,000,000.

There had been no statewide general tax increase in the state since the 1930s and annual expenditures per pupil were $352, as compared with a national average of $452; average annual salaries for classroom teachers were $5,160, as compared with a national average of $6,220. After four Oklahoma Education association-sponsored petitions to provide more money for education had failed to pass in general elections, in 1965 the National Education Association was asked to apply sanctions warning out-of-state teachers against accepting jobs there. The state legislature enacted as an emergency measure a 25% increase in the biennial education budget, the largest increase in Oklahoma's history. Also, the state constitution was amended to permit local school districts to raise their taxes for schools by ten mills, and the sanctions were lifted.

Higher Education.—The Oklahoma State System of Higher Education, administered by the Oklahoma State Regents for Higher Education, has as members all state-owned senior colleges and junior colleges and one independent senior college.

The University of Oklahoma was established by the first legislative assembly of Oklahoma Territory in 1890, and opened at Norman in 1892. It is governed by a board of seven regents, appointed by the governor and confirmed by the state senate. It includes schools or colleges of arts and sciences (1892), pharmacy (1893), fine arts (1899), engineering (1904), education, graduate, law (1909), business administration (1923), university (1942), and schools of medicine (1900, Norman; 1910, Oklahoma City) and nursing (1911). The University of Oklahoma press established in 1928 is outstanding in the publication of books, covering many regional subjects and a variety of offerings including English literature, international biography and linguistics. The university owns and operates an AM and FM radio station.

Oklahoma State University of Agriculture and Applied Science at Stillwater was chartered as an agricultural and mechanical college in 1890. It comprises colleges of agriculture, arts and sciences, engineering, education, business, home economics, veterinary medicine, a technical institute and a graduate school and schools of hotel and restaurant administration and architecture.

Other state institutions of higher education include Oklahoma College of Liberal Arts (formerly Oklahoma College for Women) at Chickasha (1908); Panhandle Agricultural and Mechanical college at Goodwell (1909); Langston university at Langston (founded for Negroes in 1897); and six state-owned senior colleges at Ada, Alva, Edmond, Durant, Tahlequah and Weatherford. Oklahoma Baptist university at Shawnee (1910), independent, also is a member of the state system.

Independent colleges and universities include Oklahoma City university (Methodist, 1904); University of Tulsa (Presbyterian, 1894); Benedictine Heights college, Tulsa (Roman Catholic, 1955, outgrowth from Guthrie, 1917); Phillips university, Enid (Disciples of Christ, 1906); and Bethany-Nazarene college, Bethany (Church of the Nazarene, 1909).

HEALTH, WELFARE AND CORRECTIONS

The state constitution provided for the election of a state com-

missioner of charities and corrections to supervise and inspect charities and institutions of correction. The state maintains mental hospitals at Norman (with annex at Lexington), Vinita and Supply; sanatoriums for tuberculosis patients at Clinton and Talihina; a state school for feeble-minded children at Enid; a state school for mentally retarded white children at Pauls Valley; a state hospital and also consolidated Negro institutions for deaf, blind and orphans at Taft.

State penal institutions include Taft Training school for girls (near Taft), "Girls Town" (near Tecumseh), Helena State school for boys (near Helena), Boley State school for boys (at Boley), Taft State Children's home (near Taft), Whitaker State Children's home (near Pryor). The state penitentiary is located at McAlester and the state reformatory at Granite. Two subdivisions of the penitentiary are the vocational training school near Stringtown, and McLeod Honor farm near Ferris, both in Atoka county.

Of the state's 77 counties, about 50 have full-time health departments serving 80% of the state's population; a number of these provide full-time medical service.

The Oklahoma department of public welfare administers the programs for dependent children, the aged, the disabled, the blind, child welfare, crippled children and rehabilitation.

ECONOMY

Agriculture.—Oklahoma was a great cattle country before the first opening of land to white settlement in April 1889, and thereafter agricultural development was rapid, with millions of acres of former Indian lands added to Oklahoma Territory in eight other openings at different times. By the 1960s there were about 84,000 farms and ranches having a total of almost 40,000,000 ac. Nearly two-thirds of farms and ranches were owned by their operators. Oklahoma began its second 50 years of statehood with improved technology that kept agriculture as its most important single pursuit, soil conservation methods contributing largely to this.

Soil erosion, which began to show up even before statehood—because of early, wasteful farming methods on wide grasslands that should never have known a plow—amounted to a blight by the 1930s, aggravated by the great drought. Northwestern and western Oklahoma counties were included in the "dust bowl" region. State conservation laws in 1925 provided for protection of wildlife and promotion of forestry, irrigation and flood control. The program was expanded by the creation of the state soil commission in 1937, to co-operate with farmers in contour cultivation and terracing of farm lands and planting of cover crops to keep the soil from washing away. By the 1960s this commission had brought over 95% of the state's area within soil conservation districts under the organization and control of local farmers and ranchers.

Reclamation work to reduce flood damage along the rivers and streams has been a vital part of the water resources program in the state, in which flood control, irrigation and municipal water supply have been combined in one project. By the 1960s over 100,000 ac., principally in western Oklahoma, were irrigated. The sprinkler system of irrigation is used in some parts of eastern Oklahoma for the growing of small fruits and vegetables as well as corn and cotton, and in the panhandle, largely a livestock-growing region, for feed and forage crops.

Of cash crops, wheat is by far the most important; Oklahoma is the U.S. third most important wheat-producing state. Though wheat replaced cotton as the leading crop in the 1930s, cotton growing remains important. Other significant crops are hay, oats, peanuts, corn, sorghum, rye, pecans and a variety of fruits. Broom corn and grain sorghums were also important cash crops.

The beef cattle industry is the largest source of agricultural wealth in Oklahoma. Beef cattle, numbering well over 4,000,000, comprise chiefly Herefords, Aberdeen Angus and Shorthorn. Grazing is most important in the south-central part of the state and in the Blue Stem Bowl region in Osage county. Other livestock, raised in much smaller numbers, include hogs, sheep, horses and mules. Chickens number 3,000,000.

Lumber.—Timber is an important resource in southeastern Oklahoma. The lumber and wood products industry (excluding furniture manufacture) is valued at approximately $8,000,000 annually.

Minerals.—Oklahoma is widely known as an oil-producing state, and indeed petroleum is by far its most valuable mineral resource, being valued at around $700,000,000 annually (figure includes also natural gas, liquefied petroleum gas and natural gasoline). Oklahoma ranks about third in production among the states; it also ranks third in number of producing wells. Producing regions extend over most of the counties, generally from the north-central to the southwestern parts of the state, with a large natural gas field in the western part of the panhandle. Tulsa, the oil centre of the state, is situated near the central part of the north-central producing region; Duncan, in Stephens county, is a centre in the oil-producing region of the southwest.

In addition to fuel minerals, Oklahoma also has large reserves of metallic and other nonmetallic minerals. Among those of value to the state are zinc, dolomite, granite, lead, salt, sand and gravel, limestone and sandstone, tripoli, clays, glass sand, germanium, chat (coarse tailings from lead and zinc ores), volcanic ash, sulfur, gypsum, asphalt and ground silica. Mineral industries based on these are an important source of riches. Ada, in Pontotoc county, is noted for its great cement plants and as a centre in a region that produces petroleum, natural-gas liquids, stone, sand and gravel and clays.

Helium is found in the Oklahoma panhandle. This region, with limited fields extending into the Texas panhandle and the southern border of Kansas, comprises the only area in the United States and possibly in the world where helium is found in sufficient quantities for commercial profitable extraction. The helium plant at Keyes, Cimarron county, constructed in 1959 for the U.S. bureau of mines, was the second such plant in the United States.

Manufactures.—Manufacturing is a third mainstay in Oklahoma's economy, being based on agricultural and mineral wealth. Agricultural products provide raw materials for meat packing, canning, flour milling, feed manufacturing and textile plants; mineral wealth supplies raw materials and fuels for refining, smelting, glassmaking, petrochemical and other industries. About 95,000 persons are employed in manufacturing, the plants tending to be concentrated in the northeastern and central parts of the state.

Transportation and Communication.—Total railroad mileage is more than 5,000 mi., reaching every part of the state. The State Highway commission is responsible for more than 10,000 mi. of primary highway system. The larger cities are served by major airlines. The navigation features of the multiple-purpose Arkansas river project are being developed to link Oklahoma with the U.S. inland waterway system.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments. (M. H. W.)

OKLAHOMA CITY, capital of Oklahoma, U.S., and its largest city, the seat of Oklahoma county, is located on the North Canadian river at the approximate geographic centre of the state. Through annexations, it became the largest city in the U.S. in area (641.1 sq.mi. in 1964). Pop. (1960) 324,253, an increase of 33.2% over 1950; standard metropolitan statistical area (Canadian, Cleveland and Oklahoma counties) 511,833, an increase of 30.4%.

Oklahoma City's exact location was dictated by the existence

of a siding on the Atchison, Topeka and Santa Fe railway, originally intended for military use and known as Oklahoma station (1887). By sundown of the day the area of central Oklahoma (1,887,640 ac. known as the Oklahoma country) was opened for settlement (April 22, 1889), approximately 10,000 persons had congregated to stake land claims at a townsite adjoining the railroad stop. A provisional town government was instituted by mass meeting in May of 1889 but it was not until May 2, 1890, that formal statutory law came upon the organization of Oklahoma territory. While the name Oklahoma City was in popular use from the earliest day, the U.S. post office department did not adopt the name until 1923. A council-manager form of government, adopted in 1927, was continued under a new charter approved April 5, 1957.

The economy has been based upon agriculture, distribution and industry, and every federal census has shown substantial gains in population (for comparative population figures *see* table in OKLAHOMA: *Population*). Annual rainfall in the area is 30.22 in. and it is one of the few places where the cotton and wheat belts overlap; the city has long been an important shipping point for both crops and also for cattle. The first major urban development reached a climax in 1910, the year Oklahoma City was designated the state capital; in the three preceding years the population had doubled. After 1910 state employees increased the population and the city also benefited from the World War I boom. The first meat-packing plants were established about this time and with the coming of additional railroads wholesale trade increased.

The first well in the Oklahoma City oil field came in on Dec. 4, 1928. Characteristics of the oil industry there were the productivity of the wells; the enormous gas pressures, resulting in more than one spectacular mid-city fire; and the then unprecedented depths (4,000–7,000 ft.) of the wells. Because of the fire hazard city ordinances were passed limiting the drilling zone in the city; it was subsequently enlarged and in 1936 was further expanded to include drilling on the state capitol grounds. In the latter part of the 20th century there were in the metropolitan area about 1,800 producing wells, approximately 1,400 within the city limits.

The city enjoys diversified industry; principal products are in aircraft, petroleum refining, oil field and telephone exchange equipment, meat packing and steel fabrication. Oklahoma City is one of the nation's foremost aviation centres, with Tinker air force base, a large air matériel depot and a federal aviation agency centre for the training of students in all phases of department of commerce aviation management and technical skills.

Educational facilities include, in addition to the usual public and parochial schools, Oklahoma City university (Methodist, 1904) and the medical centre of the University of Oklahoma, which includes schools of medicine and nursing, the university hospital, a crippled children's hospital and a speech and hearing clinic. Also on the grounds are a Veterans administration hospital and the Oklahoma Medical Research institute (privately owned and operated) and its adjacent research hospital.

The civic centre includes a modern auditorium which seats 6,000 persons. Residential housing is predominantly ranch and early American in style. The city has a symphony orchestra and is the headquarters for the state library and the state historical society, which contains an outstanding collection of American Indian archives. The state fair is held there and the city is also the site of the Cowboy Hall of Fame and Museum. (GE. H. S.)

OKMULGEE, a city of east-central Oklahoma, U.S., is located 37 mi. S. of Tulsa; the seat of Okmulgee county. Capital of the Creek Nation from 1868 until Oklahoma achieved statehood in 1907, Okmulgee, a Creek word meaning "bubbling water," began to be settled by whites in the last decade of the 19th century. In 1904 oil was discovered in the vicinity and with its development, beginning in 1907, the small cattle and agricultural community boomed. Incorporated in 1908, the city adopted a council-manager form of government in 1954. In the second half of the 20th century it was the centre of an important oil-producing area. Agricultural products included beef and dairy cattle, poultry, peanuts, cotton and corn. Manufactures included petroleum and meat products, oil field equipment, glass and furniture.

Located there is the school of technical training, a branch of Oklahoma State university. The Creek Indian council house (1878), now an Indian museum, stands in the heart of the city. For comparative population figures *see* table in OKLAHOMA: *Population*. (J. D. Mo.)

OKOVANGO (OKAVANGO, Portuguese CUBANGO), a river in central Africa, about 605 mi. in length, rises in Angola about 10 mi. E. of Vila Nova on the Benguela railway. Near Caiundo, about 200 mi. from the source, the river passes from the ancient crystalline rocks of the Angolan highlands to the Kalahari formation and flows on this formation for most of the remaining 400 mi. of its course. In many places the river has cut several hundred feet into the Kalahari system exposing hard beds of calcrete or silcrete which, as at Runtu, on the Southwest African border, form bluffs or cliffs where they have been undercut by erosion at a bend. Below the Popa falls, about 10 mi. below Andara, the river forms a series of stairlike rapids, falling about 10 to 15 ft.

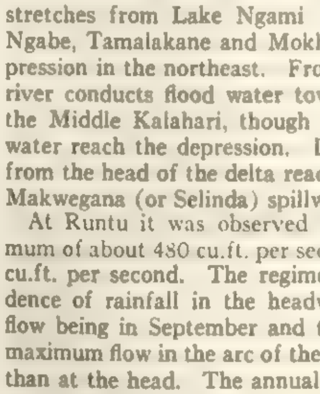
Between Runtu and Andara the Okovango receives the Cuito, which rises in the Kalahari sand and flows for nearly 450 mi. to join the main stream in an extensive flood plain. On the south side of the river the tributary channels are generally dry courses, the strongest of them being the Omuramba Omatako, which occasionally brings water to the Okovango.

For about 170 mi. below the Popa falls the river has formed a great swamp tract, the first 90 mi. of which is between about 3 and 8 mi. wide, spreading out to form a great delta, about 80 mi. long (from northwest to southeast) and 120 mi. wide (from southwest to northeast). From west to east the main distributaries are: the Taokhe, the Jiao, the Ng-gokha and the Mochaba. These flow into the channel forming the arc of the delta, which stretches from Lake Ngami (*q.v.*) in the southwest along the Ngabe, Tamalakane and Mokhokelo channels to the Mababe depression in the northeast. From the arc of the delta the Botletle river conducts flood water toward the Makarikari depression in the Middle Kalahari, though only during very high floods does water reach the depression. During very high floods, too, water from the head of the delta reaches the Linyanti marshes along the Makwegana (or Selinda) spillway.

At Runtu it was observed that the flow varied from a minimum of about 480 cu.ft. per second to a maximum of about 20,000 cu.ft. per second. The regimen corresponds closely to the incidence of rainfall in the headwater catchment basin, the lowest flow being in September and the highest in March or April, the maximum flow in the arc of the delta being about five months later than at the head. The annual discharge of the river at the head of the delta is estimated to be about 11,000,000 ac.-ft.

J.*, vol. lxii (1923); C. F. Rey, "Ngamiland and the Kalahari," *Geogr. J.*, vol. lxxx (1932); J. H. Wellington, *Southern Africa*, vol. i (1955). (J. H. Wn.)

OKRA, a herbaceous, hairy, annual plant (*Hibiscus esculentus*) of the mallow family (Malvaceae), of the old world tropics and widely cultivated or naturalized in tropical and subtropical countries. The leaves are heart-shaped, three to five lobed; the flowers are yellow with a crimson centre. The fruit or pod, the *bendikai* of the Europeans of southern India, is a tapering, ten-angled capsule, four to ten inches in length (except in the dwarf varieties), and contains numerous oval, dark-coloured seeds, hairy at the base. Only the tender, unripe fruit, called gumbo, is eaten, either pickled or prepared like asparagus. It is also an ingredient in various dishes (*e.g.*, the gumbos of the southern United States); and because of the large amount of mucilage it contains, it is extensively used for thickening



BY COURTESY OF THE UNITED STATES DEPARTMENT OF AGRICULTURE

OKRA (HIBISCUS ESCULENTUS) SHOWING PODS IN PRIME CONDITION FOR USE AS FOOD

broths and soups. The fruit is grown on a large scale in the vicinity of Istanbul. In some countries the seeds are used as a substitute for coffee. From their demulcent and emollient properties, the leaves and immature fruit long have been in repute in the east for use in poultices and fomentations.

The musk mallow or abelmosk (*Hibiscus moschatus*), a related plant indigenous to India and cultivated in most warm regions of the globe, is a low, slightly woody plant, bearing a conical five-ridged pod about three inches in length, within which are numerous brown reniform seeds, smaller than those of *H. esculentus*. The seeds possess a musky odour caused by an oleoresin and are known to perfumers under the name of ambrette, now mostly of synthetic origin. The seeds are used in Africa as beads. The plant yields an excellent fibre and, being rich in mucilage, is employed in upper India for clarifying sugar. The best-perfumed seeds are reported to come from Martinique.

ŌKUBO TOSHIMICHI (1830–1878), one of the Japanese samurai leaders who in 1868 overthrew the shogunate and re-established the government of the emperor (*see* JAPAN: *History*). Ōkubo immediately became a dominant member of the new government formed under the emperor. After a brief government mission abroad he returned convinced of the necessity of Japan's rapid economic development. To this end he supported the establishment of technical schools, the holding of scientific and technical exhibitions, the giving of loans and subsidies to private business, and the building and management of factories by the government.

In 1873 he split with the great Saigo, one of his fellow clansmen of Satsuma, over policy toward Korea. Saigo supported a policy of conquest; Ōkubo argued that priority should be given to internal reform and development. Ōkubo's views prevailed and were adhered to until 1894, long after his death. Saigo left the government and returned to his native Satsuma to arouse the clansmen. In the troubles which soon followed the foreign policy split, Ōkubo was the chief opponent of Saigo, who led the Satsuma rebellion. The suppression of the rebellion brought upon Ōkubo the personal revenge of Saigo's sympathizers, and he was assassinated in 1878 by six clansmen. Thus Ōkubo, one of Japan's greatest leaders, was in a sense a martyr to his progressive views of government and foreign policy. (T. C. SH.)

See M. Iwata, *Ōkubo Toshimichi: The Bismarck of Japan* (1964).

ŌKUMA SHIGENOBU, MARQUIS (1838–1922), Japanese statesman and prime minister of Japan during the first part of World War I, was born in the Kyushu fief of Saga, the son of a specialist in gunnery. After a conventional education, Ōkuma turned to western (Dutch) studies under the tutelage of the missionary Guido Verbeck. Ōkuma and his friends were not able to persuade their lord to join the great southwestern fiefs in the Restoration movement of 1868, and as a result they took second place to leaders from those fiefs in the new Meiji government. Ōkuma's ability and courage, however, made up for some of these disadvantages, and he played an important role in politics. From 1869 to 1881 he was principally responsible for the modernization and reorganization of Japan's fiscal system.

In 1881 Ōkuma responded to an imperial request for recommendations by presenting the draft of a constitution but his colleagues considered it radical and ill-advised. As he was about to be forced from office he exposed flagrant corruption in proposed sales of government property in Hokkaido. His action precipitated the Meiji emperor's promise of a constitution by 1889. Ōkuma then formed a political party, the *Kaishintō* (Progressive party), and challenged Itagaki Taisuke's leadership of the parliamentary movement. He also purchased the newspaper *Hōchi shimbun* and founded what became Waseda university in 1882.

Ōkuma several times interrupted his campaign against the government to give full co-operation to his former colleagues. In 1888 he became foreign minister in the Kuroda cabinet, but resigned the following year after an attack by an ultranationalist that nearly cost him his life. In 1896 he served again as foreign minister, and two years later he and Itagaki joined forces to form the Constitutional Government party (*Kenseitō*). The new party was permitted to form a government with Ōkuma as prime minister (1898) but it foundered over patronage disputes. In 1907 Ōkuma retired from politics to devote his full time to Waseda university, only to be recalled as prime minister in 1914. During this, his last premiership, Japan entered World War I and experienced a great economic boom. Efforts to force China to make long-term grants of Russian and German concessions the Japanese had taken over led to the Twenty-one Demands of 1915. These made Japan the object of the rising tide of nationalist indignation that stirred China after World War I. Ōkuma resigned in 1916 and retired from politics because of ill-health. He died on Jan. 10, 1922, at Tokyo. *See* also JAPAN: *History*. (M. B. J.)

OLAF (OLAFR; O. E. ANLAF), two kings of the Norse kingdoms of Northumbria and Dublin.

OLAF GUTHFRITHSON (d. 941) became king of Dublin on the death of his father in 934. He was continually involved in plunder in Ireland till Aug. 937, when he led a considerable force to England and was joined by Constantine of Scotland and Owain of Strathclyde. The confederacy was defeated by Aethelstan at Brunanburh, and Olaf fled to Ireland. There he was again occupied with plunder till 939, when he seized York. He entered into a vigorous campaign in the midlands in 940. Edmund I, who had succeeded Aethelstan in 939, hastened to meet him, and a treaty was concluded which gave Olaf Northumbria and part of Danish Mercia. Olaf died in 941 while plundering at Tyninghame near Dunbar.

OLAF SIHTRICSON (d. 981), nicknamed Cwaran ("of the sock" or "sandal"), was, like Olaf Guthfrithson, held in Irish tradition to be a great-grandson of Ivar (Imhar). He may have been present at Brunanburh in a subordinate capacity. He succeeded to Northumbria on the death of Olaf Guthfrithson, while Blacare, another son of Guthfrith, took the kingdom of Dublin. In 942 Olaf's power in the midlands was destroyed by Edmund, and in 943 he was deposed by the Northumbrians, who appointed one Raegnald in his place. Olaf and Raegnald now sought the friendship of Edmund and were baptized. They perhaps attempted to rule jointly, but in 944 Edmund expelled them both from Northumbria. Olaf fled to Ireland and was allowed by Blacare to assume the kingship of Dublin. He ruled turbulently for some years, and then in 949 he returned to Northumbria and became king, but was driven away in 952. His reign fell between the two reigns of Eric Bloodaxe. In his absence, Blacare had ruled Dublin but had fallen in battle (948) with Congalach, king of Ireland. Olaf re-established himself at Dublin (*c.* 951) and had an eventful reign. Congalach fell in battle against him in 956. In 980, however, Olaf suffered a disastrous defeat from Maelsechlain, afterward king of Ireland, at Tara, and withdrew on pilgrimage to Iona, where he died in 981.

Northumbrian coins minted for both Olafs are extant.

OLAF (OLAV), the name of several kings of Norway.

OLAF I TRYGGVESSON (*c.* 964–1000), king of Norway from 995 to 1000, was a great grandson of Harald I Haarfager and the son of Tryggvi Olafsson, a petty king of southeastern Norway. Olaf was born shortly after his father had been killed by one of the sons of Eric "Bloodaxe." His mother, Astrid, fled and, according to the story, Olaf reached the court of Vladimir the Saint in Russia while still a child. A contemporary poet says that he left Russia at an early age and lived for some years as a Viking, pillaging the coasts of the Baltic and the British Isles.

According to one version of the Anglo-Saxon Chronicle, Olaf was leader of the Viking army which defeated and killed the famous Anglo-Saxon chieftain Byrhtnoth in the battle of Maldon (991). In 994, with the help of Sweyn I, king of Denmark, Olaf besieged London. The city resisted and the Vikings retired to pillage southeastern England, subsequently concluding a treaty with Aethelred II. Olaf was already a Christian, but it is not known when or where he had been converted. According to a medieval legend, now proved fictitious, he had been baptized by a hermit in the Scilly Isles. He was confirmed at Andover after

the treaty of 994, and Aethelred was his sponsor.

In 995 Olaf sailed to Norway. The heathen ruler, Haakon the Great, had grown unpopular, and Olaf was quickly proclaimed king. His short reign was among the most memorable in the history of Norway.

The medieval historians of Iceland and Norway depict Olaf as single-minded in his devotion to the Christian cause, converting his subjects ruthlessly, by persuasion, persecution and guile. In fact, he had little influence in the interior of Norway, although the people of the coastal districts were compelled to submit to baptism. It was said also that Olaf caused the conversion of the Norse settlements in Orkney, the Faeroe Islands and Greenland. Although he never went there, his influence on Iceland was most radical and lasting. At his instigation, Christianity was made the official religion of that country in the year 1000.

Olaf's reign ended abruptly in this same year. Although the circumstances are not clear, it is plain that Sweyn I of Denmark and Olaf Skötkonung of Sweden had allied against Olaf Tryggvesson. Olaf had sailed to Wendland (Poland) in his mighty ship the "Long Serpent," accompanied by a magnificent fleet. After some negotiations with Boleslaw I, king of Poland, Olaf turned back, but was waylaid by Sweyn and his allies near the island of Swold (or Svold), said to lie off the coast of Wendland. Olaf's heroic defense and death were widely celebrated by the poets of the north.

Olaf II Haraldsson (*c.* 995–1030), king of Norway from 1015 to 1030 and the country's patron saint, was a descendant of Harald I Haarfager. Olaf grew up a pagan and, in early youth, lived as a Viking in Scandinavia and the Baltic lands. In 1009, the contemporary poets imply, Olaf landed at Sandwich in the great Danish army commanded by Thorkel the Tall. He engaged in several battles against the English (1009–11) and later went to France and probably to Spain. He was baptized in Rouen (*c.* 1013), and this was the turning point in his career. He returned to England in 1014 and soon afterward sailed to Norway to assert his claims to the throne.

Olaf reached Norway at a propitious moment. The country had lost its independence on the death of Olaf Tryggvesson and was now divided. Southern regions were subject to the king of Denmark and some of the eastern ones to the king of the Swedes. The west was ruled by Jarl Eric, son of Haakon the Great, who acknowledged the suzerainty of the king of Denmark. Eric was now abroad, and his son, Haakon, and brother, Sweyn, were quickly defeated by Olaf's forces and driven into exile. Olaf was master of all Norway by 1016. He proved to be a hard ruler and an ardent protagonist of the Christian religion. Although Norway had been Christian in name since the reign of Olaf Tryggvesson, Christian religion had hardly penetrated beyond the coasts, and pagan worship persisted. Olaf had brought clerics from England, and he set out to organize the church in Norway, probably on the English model.

Olaf appealed to national sentiment, but many chiefs resented his interference and revolted. He had also to face trouble with foreign monarchs. Early in his reign he conflicted with his namesake Olaf Skötkonung, king of the Swedes, but later (1019) he made peace with him, having married his daughter, Astrid. His differences with Canute, king of England and Denmark, were more serious. When Canute pressed his claims to the overlordship of Norway, Olaf concluded an alliance with Anund, Olaf Skötkonung's son and successor. Together they plundered Danish provinces (1026), but Canute surprised and repelled them with a large fleet at the mouth of the Holy river (Helge Å), to the east of Skaane. In 1027 Canute sent agents to Norway to incite chieftains against Olaf, and in 1028 he went to Trondheim himself and was proclaimed king. Olaf fled to Russia, where he remained until 1030. He then returned to Norway through Sweden, and his old ally Anund supplied some troops. Olaf's army was of poor quality, and he was killed when he met a well-organized and greatly superior force at Stiklestad, about 40 mi. from the city of Trondheim.

No battle in Norse history made a deeper impression on popular imagination than that at Stiklestad. In the heat of it, the sun was eclipsed, from which it may be deduced that it was fought on Aug. 31, 1030, and not on July 29, as the chroniclers say. Miracles were claimed to have occurred immediately after the king's death, and a year later, it was said, his body rose whole and uncorrupt to the surface of the ground. His cult spread rapidly throughout Norway and far beyond it. In fact, Olaf exercised a far greater influence after his death than he did while alive. His feast day is July 29, the traditional date of his death.

Olaf III Haraldsson (d. 1093), nicknamed "the Quiet" (*Kyrri*), was king of Norway from 1066 to 1093. Olaf had followed his father, Harald III Hardraade, on the expedition to England on which Harald was killed in 1066. After his father's death Olaf ruled jointly with his brother Magnus (d. 1069) and then as sole king. His reign was one of the longest, most prosperous and least eventful in the history of Norway. He built a number of churches and founded several towns, including Bergen. He won great popularity and was remembered for generosity and benevolence toward his subjects.

Olaf Magnusson (*c.* 1099–1115), illegitimate son of Magnus II Barfot, is often counted in regnal lists of Norway as Olaf IV. On the death of his father in 1103, he was proclaimed king jointly with his elder brothers, Eysteinn and Sigurd, who administered Olaf's share of the kingdom until his death.

Olaf IV (1370–1387), king of Denmark from 1376 to 1387 and of Norway from 1380 to 1387, was the son of Haakon VI and of Margaret, daughter of Valdemar IV, king of Denmark. After Valdemar's death in 1375, Olaf was elected (1376) king of Denmark and succeeded his father as king of Norway in 1380. The government of Norway was conducted by a state council, but power was largely in the hands of Olaf's mother, who planned to unite Norway, Sweden and Denmark. Olaf attained majority in 1385 but died two years later. (G. T.-P.)

Olav V (1903–), king of Norway from 1957, the only child of Prince Charles of Denmark (afterward King Haakon VII) and Princess Maud, youngest daughter of Edward VII of England, was born at Appleton House, near Sandringham in England, on July 2, 1903, two years before his father's election to the throne of Norway. He received the name of Olav on his arrival in Norway in 1905. Olav attended the Norwegian Military Academy from 1921 to 1924 and then went to Balliol College, Oxford, until 1926. He early distinguished himself as a ski-jumper in the Holmenkollen competition, and as a yachtsman was successful in many regattas and at the Olympic Games in 1928. On March 21, 1929, he married Princess Martha (1901–54) of Sweden. There were three children of the marriage, two daughters, and a son, Harald (b. Feb. 21, 1937). In 1940, when the Germans invaded Norway, Prince Olav escaped from Oslo with his father and the latter's ministers, with whom he finally reached England; and in June 1944 he was named head of the Norwegian armed forces.

Olav returned to Norway in May 1941, to act as regent till his father returned in June. He was regent again from June 1955, when his father had an accident, to Sept. 21, 1957, when he became king on his father's death. He made many visits to foreign countries; *e.g.*, to France and to Great Britain in 1962 and to Yugoslavia in 1966. (G. M. G.-H.)

OLAF Skötkonung (*c.* 995–1022), king of Sweden, son of Eric the Victorious. At home he followed a Christian policy without enforcing conversion, while his foreign policy was consistent opposition to the growth of a strong Norwegian state. Hence he joined King Sweyn I of Denmark in a victorious war against Norway in 1000, and married his illegitimate daughter Holmfrith to Sweyn Jarl, one of the Danish viceroys in Norway. His attitude softened in the reign of Olaf II Haraldsson, who married his other illegitimate daughter, Astrid. His legitimate daughter, Ingigerth, married Yaroslav, grand duke of Kiev. (Al. C.)

OLANCHO, a large department in southeastern Honduras that includes nearly 22% of the national area. Pop. (1961) 110,744, of which almost 80% was rural. Juticalpa, the departmental capital and largest town (pop. 7,210 in 1961), is connected with the national capital, Tegucigalpa, by an all-weather road 130 mi. long. The mountainous western third of the department has most of the population; the rest of the area consists mostly of very rainy forested lowlands with no roads and few people. Agri-

cultural production is largely in the mountain valleys; the department ranks first in Honduras in the production of cattle and swine, and third in output of coffee, cotton and beans. Other significant products are corn, rice, potatoes, gold and handicraft articles. (C. F. J.)

ÖLAND, a Swedish island in the Baltic sea, stretches for 85 mi. along the east coast of the southern extremity of Sweden from which it is separated by Kalmar sound which is from 5 to 15 mi. wide. After Gotland it is the largest Swedish island, with an area of 520 sq.mi.; its greatest breadth is 10 mi.: pop. (1960) 23,265. The centre of the island is more densely populated than either end. The only large town is Borgholm, with 2,488 inhabitants.

The island consists for the most part of Silurian limestone, and thus forms a striking contrast to the granitic, gneissic mainland. The limestone is burned for lime as well as being cut and polished. Down the west side runs a limestone ridge, rising usually in terraces, but at times in steep cliffs, to a height of 200 ft.; and along the east side there is a parallel ridge of sand, resting on limestone, never exceeding 90 ft. These ridges, known as the Western and Eastern Landborgar, are connected toward the north and the south by belts of sand and heath, and the hollow between them is occupied by a desolate and almost barren tract. The southern portion, or Alvaret, presents a surface of bare limestone characteristically weathered. Outside the ridges Öland is wooded, while the narrow strip of alluvial coastland is good agricultural country. There are a few small streams on the island and one lake, Hornsjö, about 3 mi. long.

For administrative purposes Öland is included in the Kalmar län (county). From the raid of Ragnar Lodbrok's sons in 775 onward Öland is frequently mentioned in Scandinavian history, and especially as a battleground in the wars between Denmark and the northern kingdoms. In the middle ages it formed a separate legislative and administrative unit. A number of monuments of unknown age exist, including stones (*stensättningar*) arranged in groups to represent ships. Borgholm has one of the finest castle ruins in Sweden. The town was founded in 1816, but the castle, dating at least from the 13th century, was one of the strongest fortresses and afterward one of the finest palaces in the country. The inhabitants were formerly styled Öningar, and show considerable diversity of origin in the matter of speech, local customs and physical appearance.

OLAUS MAGNUS: *see* MAGNUS, OLAUS.

OLBERS, (HEINRICH) WILHELM (MATTHÄUS) (1758–1840), German astronomer, who paid special attention to comets and the minor planets, was born on Oct. 11, 1758, at Arbergen, a village near Bremen, where his father was minister. He studied medicine at Göttingen, 1777–80, attending at the same time Kaestner's mathematical course. In 1779 he devised a new method of calculating cometary orbits. The treatise containing this important invention was made public by Baron von Zach under the title *Ueber die leichteste und bequemste Methode, die Bahn eines Cometen zu berechnen* (1797). A table of 87 calculated orbits was appended, enlarged by Johann Encke in the second edition (1847) to 178 and by Johann Galle in the third (1864) to 242. In 1781 Olbers settled as a physician in Bremen, where he practised until his retirement on Jan. 1, 1823. The greater part of each night was meanwhile devoted to astronomy, the upper portion of his house having been equipped for use as an observatory.

The comet of 1815 (period 74 years) bears his name in commemoration of its detection by him. He also took a leading part in the discovery of the minor planets, rediscovering Ceres on Jan. 1, 1802, and discovering Pallas on March 28 following. His hypothesis of their origin by the disruption of a primitive large planet (*Monatliche Correspondenz*, vi, 88) seemed to gain confirmation by the finding of Juno by C. L. Harding, and of Vesta by himself in regions indicated by the hypothesis. Olbers' theoretical investigation of the brightness of the sky to be expected on the hypothesis of an infinite static universe of stars is of great importance to modern cosmology. (*See* J. E. Bode, *Astronomisches Jahrbuch*, p. 110, 1826, and H. Bondi, *Cosmology*, pp. 19–26, 1952.)

Olbers died at Bremen on March 2, 1840. He was twice married, and one son survived him.

See C. Schilling, *Wilhelm Olbers, sein Leben und seine Werke* (1894 and 1900); Olbers' unique collection of works relating to comets now forms part of the Pulkovo library.

OLD-AGE PENSIONS: *see* PENSION; SOCIAL SECURITY.

OLD BELIEVERS (RASKOLNIKI ["Schismatics"], STAROVERI, STAROOBRYADTSI) separated from the main Russian Orthodox Church at the time of the reforms of Patriarch Nikon (*q.v.*; 1652–67), who aimed at a return to the Greek liturgical tradition. The Old Believers, notably the archpriests Neronov and Avvakum Petrovich (*q.v.*), supported the "old rite," consisting of many purely local Russian developments. However, in a series of councils culminating in that of 1666–67 the patriarch prevailed and the schismatics were excommunicated and severely persecuted. They were most numerous in the inaccessible regions of north and east Russia (but later also in Moscow itself), and were important in the colonization of these remote areas. Opposed to all change, they strongly resisted the western innovations introduced by Peter I, whom they regarded as Antichrist. Having no episcopal hierarchy they split into two groups: the *Popovtsi*, who sought to attract ordained priests and were able to set up an episcopate in the 19th century; and the *Bezpopovtsi*, who renounced both priests and sacraments. Out of both groups have developed many other sects, some with very extravagant practices. Enmity between the tsarist state and church and the Old Believers continued in varying degrees of violence up to the edict of toleration, April 17, 1905.

Most of the groups of Old Believers survived the Revolution (1917) and the branches of the *Popovtsi* that had established their own hierarchies succeeded in becoming registered and thus officially recognized by the Soviet state. Those known to be in existence are the convention of Belaya Krinitsa with its centre in the Rogozhski cemetery, Moscow (estimated membership 800,000); the Old Believer church of the Ancient Orthodox Christians (derived from the so-called *Beglopopovshchina*, "fugitive priests"), with its centre at Kuibyshev; and the Edinovertsi, a group dating from the early 19th century that is under the jurisdiction of the Moscow patriarchate and has a church in Moscow.

Two large communities of *Bezpopovtsi* in Moscow, the Preobrazhenskoe (Transfiguration) cemetery group and the so-called Pomortsi, together with those in Lithuania (centred in Vilnius) and in Latvia (centred in Riga), as well as numerous small groups elsewhere, are officially recognized. They were allowed to publish a church calendar in 1962. Little is known, however, of the Old Believer settlements supposed to exist in Siberia, the Urals, Kazakhstan and the Altai. Some Old Believers outside Russia have been resettled: 1,250 from China in Brazil (1958–61), and, from Turkey, 1,000 back to the Soviet Union and in 1962, under sponsorship of the Tolstoy foundation, 250 to the United States. These groups have remained especially faithful to their 17th-century way of life, and like all Old Believers have a remarkably efficient economic management.

OLDBURY, a municipal borough (1935) of Worcestershire, Eng., lies 6 mi. W. of Birmingham by road. Pop. (1961) 53,948. It is an old "burh," so named by the Anglo-Saxons who found it an ancient and possibly deserted British settlement. It was crown property until 1214. Architecturally "Ye Big House" (1705) is a fine example of the Queen Anne period and the Courthouse is early 19th century. There are 12 parks and recreation grounds, a sports centre, and a golf course. The town has a variety of industries, the principal ones being steel tubes and chemicals, including plastics. Oldbury is linked to surrounding areas by a comprehensive omnibus service and two passenger railway stations with goods yards. (K. PE.)

OLDCASTLE, SIR JOHN (*c.* 1378–1417), English Lollard leader, was the son of Sir Richard Oldcastle of Almeley, Herefordshire. He took part in the Scottish campaign of 1400, and sat in parliament for Herefordshire in 1404. His service in the Welsh

wars won him the friendship of Henry, prince of Wales. In 1408 he married Joan, heiress of John, 3rd Lord Cobham, of Cooling castle, Kent, and in her right was summoned to parliament as a baron in 1409. Warned about his Lollard activities by Archbishop Arundel of Canterbury in 1410, Oldcastle was summoned before convocation in March 1413, when fresh evidence came to light. His connection with the new king earned him every consideration, but he did not respond to Henry V's personal appeals to submit, and, on Sept. 23, he was brought to trial. He proved an obdurate and conscientious heretic: he rejected transubstantiation and denied the necessity of penance and confession, declaring that popes, cardinals and bishops could not dictate belief on such matters. He was convicted as a heretic on Sept. 25, but the king granted a stay of execution for 40 days. On Oct. 19 Oldcastle escaped from the Tower and took refuge with a Lollard bookseller of Smithfield, named William Fisher. There he planned a desperate adventure. Conspirators dressed as Twelfth Night mummers were to seize the king at Eltham palace, in Kent, while Lollards from all over the country were summoned to assemble at St. Giles's fields, near Temple Bar on the night of Jan. 9–10, 1414. The response was small; the king, forewarned by his agents, removed to London, and the assembled Lollards were easily captured or dispersed. Oldcastle himself escaped into the Welsh marches, and for nearly four years evaded capture. He was taken, after a fight, near Welshpool in Nov. 1417. Parliament formally reiterated his condemnation, and on Dec. 14 he was hung above a slow fire, which consumed him "gallows and all." His deep religious conviction and personal bravery command respect, for few Lollards of his class were prepared to suffer for their belief; but his abortive rising weakened his cause by branding it as treasonable.

In *The Famous Victories of Henry V*, the source play for Shakespeare's *Henry IV*, Sir John Oldcastle appears briefly as a friend of Prince Hal and has apparently been engaged with him in robbing the king's tax receivers. Shakespeare kept the name in the first version of *Henry IV*, but changed it to Falstaff before the play was registered in 1598, probably because of protests by the 7th or 8th Lord Cobham. In a play registered as *The First Part of the History of the Life of Sir John Oldcastle, Lord Cobham* in 1600, Sir John appears as a generous and loyal nobleman, the prestige of whose support is sought by dynastic opponents of the Lancastrian regime as well as by Lollard rebels.

OLD CATHOLICS is the name commonly given to, and accepted by, groups of western Christians who believe themselves to maintain in complete loyalty the doctrine and traditions of the undivided church but who separated from the see of Rome after the first Vatican council of 1869–70.

Origins.—The steady process of centralization in the see of Rome and in the person of the pope, which has marked the later history of the church in the west, has naturally led to recurrent opposition. This has taken a variety of forms—for instance, conciliarism in the 15th century and Jansenism in the 17th. A new wave of opposition was released by the plans for the first Vatican council and the promulgation of the doctrine of the infallibility of the pope in 1870 (*see* COUNCIL: *First Vatican Council* [*1869–70*]; INFALLIBILITY; VATICAN COUNCILS). There was widespread hostility to these plans, the most notable figure being the church historian J. J. I. von Döllinger (*q.v.*), who was one of the most outstanding Roman Catholic scholars of the period. After the council, all the bishops of the opposition one by one gave in their adhesion to the new dogma. Döllinger remained obdurate and in course of time was excommunicated by name. He himself took no part in the formation of separatist churches, but it was largely as a result of his wise advice and prudent guidance that Old Catholic churches came into being in a number of countries—Germany, Switzerland, Austria and elsewhere. As no bishop had joined any of these groups, recourse was had to the Jansenist church in Holland, which had maintained a somewhat precarious existence in separation from Rome since the 18th century but had preserved an episcopal succession recognized by Rome as valid though irregular. The first consecration of the new order was that of Joseph H. Reinkens to be bishop in Germany carried out by Bishop Heykamp of Deventer on Aug. 11, 1873. Rather later and for similar reasons, though with a certain national emphasis, the Polish National Catholic Church came into being in the United States and Canada. The episcopal succession was transmitted to this church in 1897 by Bishop E. Herzog of Switzerland.

Organization.—In 1889 the Union of Utrecht was formed and the declaration of Utrecht, issued in that year by the Old Catholic bishops, is the charter of Old Catholic doctrine and polity. To the union adhere: the Jansenist Church of Holland, with three bishops and about 12,000 members; the Old Catholic Church of Germany, with two bishops and about 40,000 members; the Christian Catholic Church of Switzerland, with one bishop and 30,000 members; the Old Catholic Church of Austria, with one bishop and about 40,000 members; the Polish National Catholic Church with five bishops and 250,000 members, mostly in the eastern part of the United States. The Old Catholic churches in Poland, Czechoslovakia and Yugoslavia suffered severely during and after World War II. The name "Old Catholic" is sometimes used of other small sects directed by *episcopi vagantes* (*q.v.*), unrecognized bishops; but this is an inaccuracy.

The chief authority in the Old Catholic churches is the conference of bishops. The archbishop of Utrecht exercises a kind of honorary primacy. Each diocese has its synod, with full participation of both clergy and laity in every aspect of the life of the church, including the election of bishops.

Theological Position.—Döllinger at the start laid down the vocation of the Old Catholic churches in three propositions: (1) "to bear witness *for* the truth and *against* new-fangled errors, especially the disastrous and arbitrary development of new articles of the faith; (2) gradually to bring into being a Church which will be more closely conformed to the ancient undivided Church; (3) to serve as an instrument for a future great reunion of separated Christians and Churches."

Taking these principles as their basis, the Old Catholics deny that they teach anything which is contrary to the doctrine and traditions of the Catholic Church. They accept the Scriptures, the Apostles' and Nicene creeds and the dogmatic decisions of the first seven ecumenical councils. They uphold the conciliar basis of the church and accord a high place to tradition, regarding it as the means by which the purity and completeness of the truth revealed in Scripture is safeguarded in the church. They accept seven sacraments as of permanent obligation in the life of the church. The episcopate is accepted according to the Cyprianic doctrine as a gift given by God to the church, in which all Catholic bishops share equally, having been admitted thereto by bishops who themselves stand in unbroken historical succession from the time of the apostles.

Many differences in practice, some perhaps introduced under Protestant influence, separate Old Catholics from Roman Catholics. By adopting in all countries the use of the vernacular in public worship, the Old Catholics accepted what at the time was regarded as one of the fundamental principles of the Protestant Reformation. Confession to God in the presence of a priest is not obligatory. Celibacy of the clergy was made optional in Germany in 1878 and in Holland in 1923.

Ecumenical Relationships.—The third of Döllinger's principles pledged the Old Catholics from the start to work persistently for Christian union. This was stressed at the first Bonn conference on Christian union, held in 1874, and was repeated at all the international Old Catholic congresses, held at intervals of roughly five years. The *Internationale Kirchliche Zeitschrift* (founded in 1893 as the *Internationale Theologische Zeitschrift*) renders unique service as a reliable and unprejudiced sourcebook on interchurch relationships throughout the world. In 1931, by the agreement of Bonn, full intercommunion was established between the Church of England and the Old Catholic churches; this was followed in 1946 by a similar agreement between the Polish National

Catholic Church and the Protestant Episcopal Church in the United States. Most of the Anglican churches have accepted these agreements; through mutual participation in episcopal consecrations rather more than half the Anglican episcopate in the world has the Old Catholic as well as the Anglican episcopal succession. The Old Catholic Churches also share in the work of the World Council of Churches. *See* also ECUMENICAL MOVEMENT.

OLD CHURCH SLAVONIC, one of the southern group of the Slavic languages (*q.v.*). In 862 Prince Rostislav of the Great Moravian state moved to counter the influence of the German clergy in his domains and appealed to Constantinople for Christian missionaries who could preach to his people in their own tongue and train a native priesthood. The Greeks responded by sending the brothers Constantine (better known by the name Cyril, which he assumed when he was shorn monk) and Methodius, who were natives of Salonika and knew the Slavonic dialect of that region (*see* CYRIL AND METHODIUS, SAINTS). It was doubtless on the basis of that dialect, for which Cyril created a special alphabet, that the brothers undertook the great task of founding the first Slavonic literary language, translating into it the religious texts needed for their mission. Since the oldest extant manuscripts date from more than a century later, none of their writings have survived in their original form, and it is possible to reconstruct only incompletely the language used by them and their immediate disciples—a language which, moreover, quickly adopted varying norms in the early centres of Slavonic literary culture.

The general term "Church Slavonic" (as in "Croatian Church Slavonic" and "Russian Church Slavonic") is used to cover these various developments, through which the Cyrillo-Methodian linguistic tradition has exerted a powerful influence on the modern literary languages of the Orthodox Slavs. The name "Old Church Slavonic" (or, somewhat misleadingly, "Old Slavonic" or "Old Bulgarian") is reserved for the fairly faithful, but not entirely homogeneous, reflection of that tradition found in a small number of South and West Slavonic texts antedating the 12th century. These include translations from a Roman Sacramentary (*Kiev Fragments*), the four Gospels (*Codex Zographensis, Cod. Marianus*), the Evangeliarium or liturgical Gospel readings (*Cod. Assemanianus, Sava Book*), the Psalter (*Psalterium Sinaiticum*), the Euchologium (*Euch. Sinaiticum*), the Menaea (*Cod. Suprasliensis*) and homiletic literature (*Glagolita Clozianus*). Of these most important manuscripts, two (*Sava, Suprasliensis*) are written in Cyrillic, the others being in the Glagolitic alphabet.

The fact that Cyril and Methodius could successfully import their language into West Slavonic territory indicates how closely Slavonic linguistic unity was still maintained in the 9th century. Indeed, in many respects Old Church Slavonic (O.Ch.S.) coincides with a reconstruction of Common Slavonic (C.S.). It has, for example, preserved the nasal vowels in their Common Slavonic distribution: *cf.* C.S. **rǫka, *pętь*, O.Ch.S. *rǫka, petь*—Russian *ruká, pjat'*, Polish *ręka, pięć*. The jers (ъ, ь)—which have normally, in the modern Slavonic languages, coalesced with other vowels or disappeared, depending on their position—are regularly maintained in all positions in O.Ch.S. and kept distinct from the other vowels: *cf.* O.Ch.S. *sъnъ, dьnь*, Russian *son, den'*, Serbo-Croatian *sȁn, dân*, Bulgarian *sъn, den*. The vowel *jat'* (*ě*) is likewise distinguished from the other vowels: *cf.* O.Ch.S. *lěto*, Pol. *lato*, Ser.-Crt. *lȇto, ljȇto, lȉto*. In its morphology, the language is equally conservative. At the same time, O.Ch.S. shares certain characteristic phonological developments with other South Slavonic dialects, notably (1) its treatment of so-called *tort*-groups (C.S. *o* or *e* plus following *r* or *l* between consonants), (2) elimination of C.S. *d* or *t* before *l* and (3) palatalization of velars before reflexes of *woi*:

(1) C.S. **golva, *bergъ*; O.Ch.S. *glava, bregъ*; Bulg. *glavá, brjag*: *cf.* Russ. *golová, béreg*; Pol. *głowa, brzeg* and Czech (resembling South Slavonic) *hlava, břeh*.

(2) O.Ch.S. *moliti sę*, Ser.-Crt. *mòliti se*: *cf.* Pol. *modlić się*; Cz. *modliti se* and Russ. (resembling South Slavonic) *molít'sja*.

(3) O.Ch.S. *cvětъ*; Ser.-Crt. *cvêt; cvȉjet, cvît*: *cf.* Pol. *kwiat*; Cz. *květ* and Russ. (resembling South Slavonic) *cvet*.

The reflexes of C.S. *tj* and *dj* are *št* and *žd* (*cf.* Bulgarian), except in the *Kiev Fragments*, which have (along with a few other West Slavonic traits) *c* and *z*. For this feature, therefore, the usage of Cyril and Methodius cannot be reconstructed with certainty. *See* also BULGARIAN LANGUAGE; SLAVIC LANGUAGES.

OLDENBARNEVELT, JOHAN VAN (1547–1619), Dutch statesman, the architect of the 12-year truce of 1609 between the Netherlands and Spain and the great victim of the political crisis of 1610–19, was born at Amersfoort on Sept. 14, 1547. After studying law at Louvain, at Bourges and at Heidelberg and traveling in France and in Italy, he settled down to practise in the law courts at The Hague. In religion a moderate Calvinist, he became a zealous adherent of William I the Silent, prince of Orange. In the earlier period of the revolt of the Netherlands against Spanish rule (*see* NETHERLANDS, THE: *History*), he served as volunteer for the attempted relief of Haarlem (1573) and again at Leiden (1574). In 1576 he became pensionary of Rotterdam. He was active in promoting the Union of Utrecht (1579) and the decision of the estates of Holland and Zeeland to offer William the title of count. On the assassination of William (July 1584) he persuaded the estates of Holland to appoint the youthful Maurice (*q.v.*) of Nassau as stadtholder and captain general, which they finally did in Nov. 1585. During the governorship of the earl of Leicester (Robert Dudley), Oldenbarnevelt led the estates of Holland in their opposition to the governor's policies.

Appointed land's advocate of Holland (*see* PENSIONARY) in 1586, Oldenbarnevelt rapidly became the leading statesman of the United Provinces. In close collaboration with Maurice he strengthened the republic internally and internationally and provided the financial and political means for Maurice's military triumphs in the following years. An important diplomatic success of his was the alliance with France and England (1596), which amounted to factual recognition of the republic's independence.

As long as the war against Spain lasted, the stadtholder and the advocate acknowledged each other's responsibilities and collaborated in harmony. In 1605, however, Oldenbarnevelt decided that the war should be brought to an end, since Henry IV of France had already made peace with Spain in 1598 and James I of England had followed his example in 1604. Complicated negotiations ensued between the states-general (dominated by Oldenbarnevelt), the leading statesmen of the southern Netherlands and the French mediator Pierre Jeannin. Within the republic, Oldenbarnevelt's peace policy was supported by the majority of the estates of Holland; but Maurice and his cousin William Louis, stadtholder of Friesland, together with the military and naval leaders and the strict Calvinist clergy, vigorously objected to it on the ground that Spain was merely seeking an interval for recuperation; and in Holland itself the prospect of having to stop fighting the Spaniards in the West Indies alarmed Amsterdam, which was becoming interested in that area. Oldenbarnevelt—through whose initiative the Dutch East India company had been formed in 1602—was fully aware of the importance of colonial trade; but he refused at this time to let this motive determine the question of peace or war. When he saw that peace could not be made, he agreed to a truce, which was concluded for 12 years on April 9, 1609. By this truce Dutch independence was recognized, at least temporarily, by Spain and the southern Netherlands.

During the truce the conflict between Arminians and Gomarists within the Calvinist church led to grave disturbances (*see* ARMINIANISM). Oldenbarnevelt upheld the cause of the Arminians

and was himself backed by the group which had enabled him to conclude the truce of 1609; *i.e.*, by the estates of Holland except Amsterdam. He tried to keep the conflict within certain limits; he refused to allow the convening of a national synod, because it would obviously have produced a majority against the Arminians; and he even forbade preachers in Holland to treat of disputed subjects from their pulpits (1614). This led to the expulsion of the recalcitrant Gomarists from towns where the urban government favoured the Arminians.

Not until July 1617 did Maurice declare himself for the Gomarists. This was a decisive step, since Maurice, as captain general of Holland, had military power and could rally those who had already opposed Oldenbarnevelt over the truce: the majority of the states-general, Amsterdam and, of course, the most orthodox Calvinists, who constituted a numerical majority in the church. Oldenbarnevelt, now on the defensive, sought to reassert himself by a counterattack and persuaded the estates of Holland to pass his "Sharp Resolution" of Aug. 4, 1617. This authorized the towns in the province to raise their own militias, which would not be subject to the captain general and so could protect the Arminians; and it also ordered the soldiers of Holland's regular army to obey the estates only. Then Maurice, whose authority was thus contested, took action to make sure that all the other provinces were prepared to follow him. On Aug. 28, 1618, the states-general granted him dictatorial power to solve the problem; and next day he had Oldenbarnevelt and his collaborators put into prison. The resistance of Holland soon collapsed.

The states-general in Feb. 1619 created a special court of 24 members to try Oldenbarnevelt, who defended himself with great dignity and acumen but was found guilty of high treason and condemned to death (May 12). On May 13, 1619, the old statesman was executed in The Hague, a victim not so much of injustice as of a political conflict that could not be settled so long as the republic's vague constitution allowed contradictory interpretations.

(E. H. K.)

OLDENBURG, a former German state, successively a countship, a duchy, a grand duchy and a *Land* before it became an administrative district of Lower Saxony (*q.v.*) in 1946. At its greatest extent, between 1854 and 1937, Oldenburg had an area of 2,480 sq.mi., comprising the main body of the territory and two exclaves, Lübeck-Eutin (209 sq.mi.) and Birkenfeld (194 sq.mi.). During this period the main body was bounded north by the North sea and encircled landward by Hanover (Prussian from 1866) except in the east, where it had a short frontier with Bremen. Its capital was Oldenburg (*q.v.*) on the lower Hunte river. Wilhelmshaven (*q.v.*), bought by Prussia in 1853, was restored to Oldenburg in 1937, when Lübeck-Eutin and Birkenfeld were transferred to Schleswig-Holstein and to the Prussian Rhine province respectively.

History.—In Carolingian times lordships in the area were held by the family of the Saxon duke Widukind, whose grandson Walbert founded the abbey of Wildeshausen, on the middle Hunte, in A.D. 851. By 1108, however, a certain Count Egilmar I had his seat at Oldenburg; and his descendants won practical independence after the fall of the Saxon duke Henry the Lion (1180), though they were not officially enfiefed as immediate vassals of the *Reich* till 1531. The nucleus of the countship lost territory through partitions between branches of the dynasty and could expand only slowly. Stedingen (on the lower Weser) was won through the crusade against the Stedingers in 1234; Friesische Wehde (Varel, Bockhorn and the country to the west) was gradually annexed in the 100 years from 1386; and Butjadingen and Stadland (between the Jade and Weser estuaries) were added in 1517–23. The archbishops of Bremen, the bishops of Münster, the counts of East Frisia and the Hanseatic city of Bremen obstructed Oldenburg's expansion.

Christian of Oldenburg became king of Denmark in 1448 and duke of Schleswig and count of Holstein in 1460 (he was also king of Norway from 1450 and of Sweden for a few years from 1457; *see* CHRISTIAN I of Denmark). In 1454 he ceded Oldenburg to his brother Gerhard (abdicated 1483; d. 1500). Gerhard's great-grandson John (d. 1603), count from 1573, acquired the lordship of Jever, west of the Jade estuary, in 1575. John's son Anton Günther (d. 1667) made good his claim to the free lordship of Knyphausen (1624) and, by remaining neutral in the Thirty Years' War, obtained from the Holy Roman emperor Ferdinand II the right of levying tolls from ships passing Elsfleth on the Weser. With no legitimate offspring, Anton Günther left Jever to the house of Anhalt-Zerbst, and Knyphausen, Varel and other titles to his bastard Anton I, count of Aldenburg. The residue, bequeathed to Denmark and to Holstein-Gottorp, was acquired by Denmark exclusively in 1676.

Christian VII of Denmark in July 1773 ceded Oldenburg to his distant cousin Paul, the future emperor of Russia, in exchange for the latter's title to Holstein-Gottorp; and in Dec. 1773 Paul gave Oldenburg to his grandfather's first cousin, Frederick Augustus, bishop of Lübeck, for whom in 1774–77 the Holy Roman emperor Joseph II erected Oldenburg into a duchy. As William, duke from 1785, was feebleminded, his cousin Peter of Holstein-Gottorp became regent. In the Napoleonic period Peter, with rights of his own to the episcopal principality of Lübeck, obtained for Oldenburg in 1803 not only Wildeshausen (from Hanover) but also Cloppenburg and Vechta (from secularized Münster) on renouncing the Elsfleth toll; but he was expelled by the French in 1806 and again, after restoration (1807), in 1810. He returned as regent in 1813; and the congress of Vienna granted the personal title of grand duke to William (who made no use of it) in 1815. The principality of Birkenfeld, on the Nahe river, was made over to Oldenburg in 1817; and Jever, which Russia had inherited from Anhalt-Zerbst in 1793, and which Peter had been administering from 1813, was ceded to Oldenburg in 1818. Peter, having succeeded William as duke in 1823, died in 1829, whereupon his son Augustus (d. 1853) proclaimed himself grand duke and his possessions a grand duchy. A patron of literature and of the drama, Augustus granted Oldenburg a constitution in 1849. Knyphausen and Varel were bought back from the counts of Bentinck (successors of the Aldenburgs) in 1854.

Oldenburg supported Prussia in the Seven Weeks' War (1866) and became a member of the North German confederation (1867) and of the German empire (1871). Frederick Augustus I (1852–1931), grand duke from 1900, abdicated in Nov. 1918; and Oldenburg became a *Land* of republican Germany. The *Land* elected a Nazi government in 1932; and Hitler made the city of Oldenburg the capital of a *Gau* extending over large parts of adjacent regions. At the end of World War II the British first installed Theodor Tantzen, a veteran of the republican era, as prime minister (May 1945), then merged Oldenburg into Lower Saxony (Nov. 1946). The Evangelical Lutheran Church of Oldenburg, however, remained independent under its own bishop, while the Roman Catholics were governed by the bishop of Münster's *Offizial* at Vechta.

Lübbing, *Oldenburgische Landesgeschichte* (1953); K. Hartong, *Beiträge zur Geschichte des oldenburgischen Staatsrechts* (1958).

(W. G. Fr.)

OLDENBURG, a city of Germany which after the partition of the nation following World War II was in the *Land* (state) of Lower Saxony in the northwestern part of the Federal Republic of Germany. It lies between Bremen and Emden on a crossing of the Hunte river about 12 mi. S.W. of its confluence with the Weser. Pop. (1961) 125,198. One of the oldest settlements in the region, it was first mentioned as a town in 1108. City status was granted in 1345 by Count Conrad I. Much of the old quarter was destroyed by fire in 1615, but the Lamberti church (1270) on the central market place survives. Formerly the seat of the grand dukes of Oldenburg, the city has a state theatre, museums, art galleries, botanical gardens, a library, academies of engineering, administration and economy, and numerous schools. Oldenburg is the market centre for the surrounding farming district; auctions

of cattle and horses are held. It has one of the largest factories for meat products in Europe; other industries include shipbuilding, glassmaking and textile manufacture. Accessible by ships of up to 1,500 tons from the Weser estuary, Oldenburg is linked by inland waterways with the Ruhr and is a rail and road junction. It is the headquarters of an administrative district.

(H.-G. RE.)

OLDHAM, JOHN (1653–1683), English poet and satirist, one of the pioneers of Augustan poetry, was born at Shipton Moyne, Gloucestershire, on Aug. 9, 1653. His father was rector of Long Newnton, Wiltshire, under the Protectorate and was ejected from his living in 1662. He had, however, "a small estate, and with the keeping of a school he had a handsome livelyhood." Oldham was educated at Tetbury school, Gloucestershire, and matriculated at St. Edmund hall, Oxford, on June 17, 1670. He took the B.A. degree in 1674 and returned home, probably to teach at his father's school. In 1676 he became an usher at Croydon school under the headmastership of John Shepheard.

His poems attracted the attention of the earl of Rochester into whose mouth he had placed some verses "supposed to be written by ye Court Hector." Rochester visited him at Croydon and is said to have "much delighted" in his poetry. Oldham's imitation of Moschus' elegy on Bion contains a touching expression of his gratitude to Rochester. In Nov. 1677 he attempted, apparently unsuccessfully, to win recognition at court by writing a poem on the marriage of the Princess Mary to William of Orange.

Oldham left Croydon for Reigate in Feb. 1679 (Old Style, 1678), to become tutor to the grandson of Sir Edward Thurland. He continued at Reigate till 1681, when he is said to have come to London and "set up for a wit." Later he was a tutor to a son of Sir William Hicks, and "at his leisure hours . . . applyed himself to the study of physic." When this tutorship ended he again betook himself to London and it was probably at this time that he met John Dryden, who lamented that Oldham was "too little, and too lately known" by him. He was introduced to William Pierrepont, earl of Kingston, and for a time "lived with him in great respect" at his house at Holm Pierrepont near Nottingham, where he died of smallpox in Dec. 1683. He was mourned by Dryden in a noble elegy.

Oldham has a notable place in the development of Augustan poetry. The four *Satyrs Upon the Jesuits* (1681), including "Garnet's Ghost," previously published as a broadsheet in 1679, constitute his most celebrated, but by no means his best, work. They are forceful, but inflated and melodramatic. With Rochester, Oldham is one of the pioneers of the "imitation" of classical satire in English, and his "imitations" of Horace, Juvenal and Boileau contain some admirable writing. There is vigour, wit and a fine note of independence in almost everything he wrote.

Thompson (1770); *Poetical Works*, selection ed. by R. Bell (1854), reprint of the second ed. (1871) with introduction by Bonamy Dobrée (1960); H. F. Brooks, "A Bibliography of John Oldham," in *The Proceedings and Papers of the Oxford Bibliographical Society*, vol. v, part i (1936), and an unpublished D.Phil. thesis on Oldham (with complete ed. of the works), in the Bodleian library, Oxford. (V. DE S. P.)

OLDHAM, a municipal, county and parliamentary borough of Lancashire, Eng., 7 mi. N.E. of Manchester. Pop. (1961) 115,346. Area 8.3 sq.mi. The town, which lies high near the source of the small Medlock river, is a modern industrial town that takes its name from the Oldham family, who, in the middle ages, held Werneth hall as their manor house. From the Oldhams was descended Hugh Oldham, who died bishop of Exeter in 1519. Linen manufacture was introduced in Oldham in 1630, when it was an agricultural town producing wool, but with the adoption of Richard Arkwright's inventions and the discovery that the moist climate was extremely suitable for cotton-spinning, the cotton industry grew with great rapidity. Oldham is now one of the chief cotton-spinning towns in the world. Its second largest industry is engineering, chiefly textile engineering, and it also produces cloth of various kinds.

The parish church of St. Mary was a medieval chapel rebuilt in 1476, and again in 1833 in the Early English style. Other public buildings and institutions include the town hall, with tetrastyle portico; the central public library, art gallery and museum, opened in 1895; and the county court. The Hulme grammar school was founded in 1606; Henshaw's Bluecoat school was opened in 1834; the Lyceum, which has schools of art and music, was founded in 1839; the Hathershaw Technical High school and Oldham College of Further Education (which superseded the old Technical college) were opened in 1954.

Alexandra park, which covers 60 ac., stands on a picturesquely undulating and terraced site. Werneth park contains a study centre and natural history museum. There are thrice-weekly markets in the town and two of the biggest fairs in the county are held there in June and September. Oldham, incorporated in 1849, became a county borough in 1888. The parliamentary borough has returned two members since 1832.

OLD POINT COMFORT, a spit of land on the southeastern tip of the peninsula between the James and York rivers in Virginia, U.S., commanding the entrance to Hampton Roads and the James river. Its strategic importance was apparent to the earliest colonists, who named it Poynt Comfort because of its sheltered harbour and established the first fortifications there in 1608.

Fort Monroe, last of a series of forts on the point, is a moated and stone-walled fort covering 63 ac., built by the government from 1819 to 1834.

During the American Civil War the Confederacy considered Fort Monroe too strong to attack and it served the Union as a base of operations for McClellan's peninsular campaign (1862) and for a series of expeditions against Confederate ports. Following the war, Jefferson Davis was imprisoned there for two years. Long a coast artillery post, Fort Monroe, after World War II, became headquarters for (successively) the army ground forces, the army field forces and the continental army command.

In 1820 a tavern was opened at Old Point to serve the men constructing the fort. The location proved attractive and by 1828 the tavern had been replaced by a hotel. This was the first of a succession of hotels, some very elaborate, that made Old Point Comfort one of Virginia's best-known resorts. (M. BR.)

OLD TESTAMENT: *see* BIBLE.

OLDYS, WILLIAM (1696–1761), English antiquary and bibliographer, one of the first to discuss earlier English writers critically. Born July 14, 1696, probably in London, he was the natural son of William Oldys, a distinguished lawyer. He lost money in the South Sea Bubble (*q.v.*) and spent some years (1724–30) in Yorkshire, often as the guest of his friend the earl of Malton. In 1727 he began to annotate a copy of Gerard Langbaine's *Dramatick Poets* (1691) with notes which had been transcribed from the original (preserved in the British museum, London) by many later commentators. In 1731 he sold his collection of books and manuscripts to Edward Harley, earl of Oxford, who became his patron and in 1738 appointed Oldys his literary secretary. Oldys' best work was a *Life of Raleigh* prefixed to his edition of Raleigh's *History of the World* (1736). In 1737 the *British Librarian*, which lists and comments on a selection of rare and valuable books, appeared.

After the earl's death in 1741, Oldys was a booksellers' hack for 14 years. With Samuel Johnson he edited the *Harleian Miscellany* (1744–46), a collection of tracts and pamphlets from the earl's library, and he contributed 22 articles to *Biographia Britannica* (1747–60). In 1751 Oldys was sent to the Fleet prison for debt, remaining there until 1753, when his debts were discharged by the duke of Norfolk, who appointed him Norroy king-of-arms in May 1755. He was modest, kindly, "critical as well as erudite" and tireless in his researches, writing his notes on slips of paper collected in small bags suspended about his room, thus accumulating much biographical material useful to later authors. His last published work was a *Life of Charles Cotton*, prefixed to an edition of the *Compleat Angler* (1760). Oldys died in London, April 15, 1761.

See I. D'Israeli, *Curiosities of Literature*, second series, vol. iii (1823); J. Yeowell, *A Literary Antiquary* (1862).

OLEANDER, the common name for any of the ornamental evergreen shrubs of the genus *Nerium*, belonging to the dogbane family (Apocynaceae; *q.v.*) and having a poisonous milky juice. The best known is the common oleander (*N. oleander*), often called rosebay, a native of the Mediterranean region, characterized by its tall shrubby habit and its thick lance-shaped opposite leaves. The flowers are borne in terminal clusters and are of a rose colour, rarely white. The hairy anthers adhere to the thickened stigma. The fruit or seed vessel consists of two long pods, which liberate a number of seeds, each of which has a tuft of silky hairs. The oleander was known to the Greeks under three names (viz., *rhododendron*, *nerion* and *rhododaphne*) and is well described by Pliny the elder, who mentions its roselike flowers and poisonous qualities. The common oleander has long been cultivated in greenhouses, and numerous varieties, differing in the colour of their flowers, which are often double, have been introduced. The sweet oleander (*N. indicum*) is a smaller plant with vanilla-scented flowers. In warm countries oleanders are widely grown outdoors.

JOHN H. GERARD

OLEANDER (NERIUM OLEANDER)

OLEASTER (Russian Olive; Trebizond Date) (*Elaeagnus angustifolia*), a handsome deciduous Eurasian tree, 15 to 20 ft. high, commonly cultivated as an ornamental and as a hedge and windbreak plant. It belongs to the oleaster family (Elaeagnaceae). The brown, smooth branches are more or less spiny; the narrow leaves are light-green above and silvery below, due to a hairy covering. The small fragrant yellow flowers, which are borne in the axils of the leaves, are silvery-scaled on the outside, as also are the one-half-inch-long, yellowish, egg-shaped fruits, which are sweet but mealy.

OLEFIN, or alkene, in organic chemistry, is the generic name given to an unsaturated hydrocarbon containing one or more pairs of doubly linked carbon atoms (*see* also Hydrocarbon). The unsaturation is represented by a double bond, C = C, which indicates the point of unsaturation and of reactivity in the molecule. The olefins are classified in either one or both of the following ways: (1) a cyclic or an acyclic (aliphatic) olefin is one in which the double bond is located between carbon atoms forming part of a cyclic or of an open-chain grouping, respectively; (2) a mono-, di-, tri- or polyolefin is one in which the number of double bonds per molecule is respectively one, two, three or an unspecified number greater than two.

The diolefins (or tri- or polyolefins) may be classified according to the relative positions of the double bonds as: (*a*) "cumulated" or "contiguous diolefins," or "allenes," containing the two double bonds adjacent to each other as in allene, or 1,2-propadiene, ($CH_2=C=CH_2$); (*b*) "conjugated diolefins," in which the double bonds are separated by one single linkage as in 1,3-butadiene ($CH_2=CH-CH=CH_2$); (*c*) "isolated diolefins," in which the double bonds are separated by at least two single linkages as in 1,4-pentadiene ($CH_2=CH-CH_2-CH=CH_2$).

The terms aliphatic, aryl, cyclic, etc., are used to indicate the form of the carbon skeleton. The terminations -ene, -diene, -triene, etc., in the systematic Geneva system of nomenclature, identify the individual hydrocarbons of mono-, di- or triolefinic structure. Sometimes the ending -ylene is given to identify a monoolefin, *e.g.*, ethylene, propylene, etc. The position of the double bond or bonds is indicated by a numerical prefix or suffix.

Olefins containing from two to four carbon atoms per molecule are gaseous at ordinary temperatures and pressures; those containing five or more carbon atoms are usually liquid at ordinary temperatures. They are only slightly soluble in water. The physical constants of some aliphatic olefins are given in the following table. In general, the boiling points are very close to those of the saturated hydrocarbons having the same carbon skeleton; the densities are slightly higher.

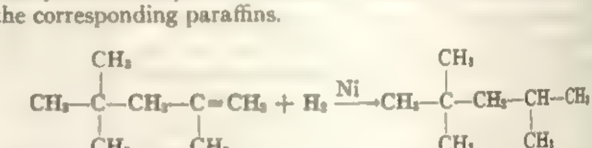
Name	Formula	Melting point °C.	Boiling point °C.	Density d_4^{20}
Ethylene	$CH_2=CH_2$	−169.4	−103.9	
Propene	$CH_3-CH=CH_2$	−185.2	−47.6	
1-Butene	$CH_3-CH_2-CH=CH_2$	−190	−6.3	
1-Pentene	$CH_3-(CH_2)_2-CH=CH_2$	−138.0	30.1	0.6410
1-Hexene	$CH_3-(CH_2)_3-CH=CH_2$	−141.0	63.7	0.6734
1-Heptene	$CH_3-(CH_2)_4-CH=CH_2$	−120.0	92.8	0.6968
1-Octene	$CH_3-(CH_2)_5-CH=CH_2$	−102.1	121.6	0.7159
1-Nonene	$CH_3-(CH_2)_6-CH=CH_2$	−88.0	145	0.7315

Monoolefins (aliphatic) have the general formula C_nH_{2n}; they are not found in nature. They are formed in large quantities during the cracking of petroleum oils to produce gasoline (*q.v.*). The olefins thus obtained are mixed with other types of hydrocarbon, from which they are separated either by physical or by chemical means.

Olefins may be prepared by the dehydration of the corresponding alcohols, removal of hydrogen halides from alkyl halides, pyrolysis of the corresponding acetates or by synthetic methods, such as:

$$CH_2=CH-CH_2Br+RMgBr \longrightarrow CH_2=CH-CH_2-R+MgBr_2$$

The principal reactions of olefins are those of the addition of various elements or groups to the two doubly linked carbon atoms. Hydrogen reacts with olefins, under the influence of catalysts such as platinum black or finely divided nickel, to form the corresponding paraffins.

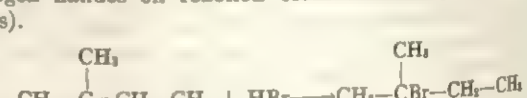


2,4,4-Trimethyl-1-pentene "diisobutylene" — 2,2,4-Trimethylpentane "isooctane"

Halogens such as chlorine, bromine and iodine add to the doubly linked carbon atoms to yield dihaloparaffins.

$$\underset{\text{2-Butene}}{CH_3-CH=CH-CH_3} + Cl_2 \longrightarrow \underset{\text{2,3-Dichlorobutane}}{CH_3-CHCl-CHCl-CH_3}$$

Hydrogen halides on reaction form monohaloparaffins (alkyl halides).

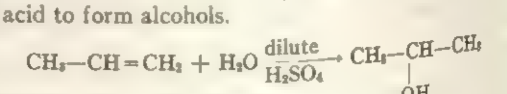


2-Methyl-2-butene — 2-Methyl-2-bromobutane

Hypochlorous or hypobromous acids combine with olefins to produce the corresponding halohydrins.

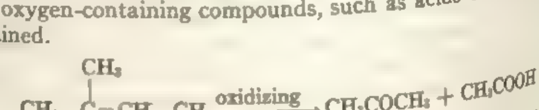
$$\underset{\text{Ethylene}}{CH_2=CH_2} + HOCl \longrightarrow \underset{\text{Ethylene chlorohydrin}}{CH_2Cl-CH_2OH}$$

Water reacts with olefins in the presence of catalysts such as sulfuric acid to form alcohols.



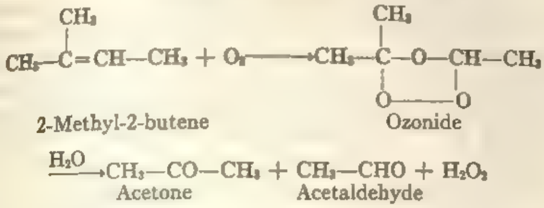
Propene — Isopropyl alcohol

Oxidation of olefins with dilute potassium permanganate results in the addition of two hydroxyl groups at the point of unsaturation to form glycols. Under the influence of stronger oxidizing agents or more drastic conditions, the double bond is ruptured and oxygen-containing compounds, such as acids or ketones, are obtained.



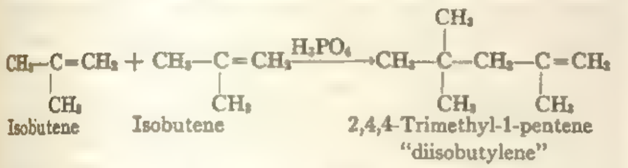
2-Methyl-2-butene — Acetone — Acetic acid

Ozone reacts with olefins in solution to form an ozonide, which, when isolated in pure form, is explosive; by treatment of the ozonide with water, the originally unsaturated carbon-carbon linkage is ruptured with the formation of aldehydes and ketones.



This reaction is employed, in particular, for the determination of the structures of olefins.

In the presence of certain catalysts, two or more molecules of olefin combine to form polymers. (*See* also POLYMERIZATION.)



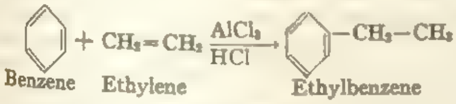
Olefins react in the presence of catalysts with organic compounds such as isoparaffins, aromatic hydrocarbons and phenols to form addition products of great industrial importance, which are used in the manufacture of aviation gasoline, synthetic rubber, detergents and plastics.

Olefins react with carbon monoxide and hydrogen under pressure in the presence of a cobalt catalyst to form aldehydes and alcohols (oxo process).

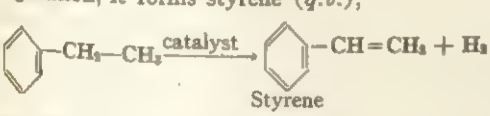
Ethylene (*q.v.*; or ethene), $CH_2=CH_2$, is the first member of the olefin series. It is one of the dominant raw materials in the organic chemical industry. A large proportion is converted into industrial ethyl alcohol and derivatives thereof.

The following are some of the commercial products obtained from ethylene: ethylene glycol (CH_2OH-CH_2OH) is produced via ethylene oxide ($\underset{O}{CH_2-CH_2}$) by selective oxidation of ethylene. Polyethylene is a plastic material of great commercial use. It can be made either at elevated pressures (1.000 atm.) and temperatures in the presence of minor amounts of peroxides, or at low pressures and low temperatures in the presence of a catalyst composed of titanium tetrachloride and metal alkyls or at medium pressures and temperatures, using chromium on silica-alumina base.

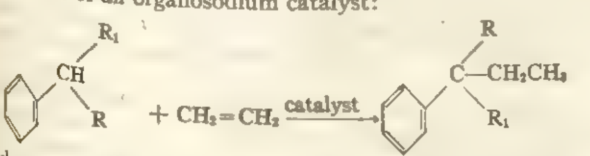
Ethylbenzene is a product of interaction of ethylene and benzene;



on dehydrogenation, it forms styrene (*q.v.*),

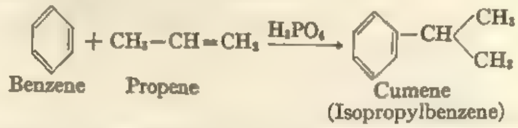


one of the important starting materials for both synthetic rubber and various plastics. Ethylene reacts with alkylbenzenes in the presence of an organosodium catalyst:



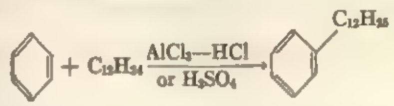
Ethylene is also used as a general anesthetic and as an agent to hasten the ripening of bananas, citrus fruits, bulbs and potatoes.

Propene (propylene), $CH_3-CH=CH_2$, is used for the synthesis of isopropyl alcohol ($CH_3-CHOH-CH_3$), which on dehydrogenation forms acetone ($CH_3-CO-CH_3$), one of the more important solvents. Propene is made to react with benzene to form cumene,



an important intermediate in the commercial manufacture of phenol and acetone.

Propene is polymerized commercially under pressure in the presence of silicophosphoric acid to form nonenes (C_9H_{18}) and dodecenes ($C_{12}H_{24}$). The nonenes are added to gasoline. The dodecenes are caused to react with benzene in the presence of a catalyst to form dodecylbenzenes:



The dodecylbenzenes are the major intermediates in the manufacture of household detergents (*see* also DETERGENTS AND WETTING AGENTS: *Types of Detergents*).

Butenes (butylenes) are used for the synthesis of butyl alcohols (C_4H_9OH). Butenes react with isobutane in the presence of sulfuric acid or hydrogen fluoride to form octanes; the latter are important constitutents in high-octane gasolines.

n-Butenes are dehydrogenated to form butadiene.

$$\underset{\text{1-Butene}}{CH_3-CH_2-CH=CH_2} \xrightarrow{\text{catalyst}} \underset{\text{1,3-Butadiene}}{CH_2=CH-CH=CH_2} + H_2$$

Isobutene polymerizes at $-78°$ C. in the presence of Friedel-Crafts type catalysts ($AlCl_3$, $FeCl_3$, etc.) to a high molecular weight hydrocarbon that is used for the manufacture of butyl rubber from which inner tubes for tires are made.

The sources of the normal-chain (*i.e.*, straight-chain) olefins are animal and vegetable waxes and oils. These are converted into alcohols, from which the corresponding olefins are obtained.

Diolefins (C_nH_{2n-2}) (dienes, alkadienes) containing conjugated double bonds are the most useful members of this series; they undergo reactions similar to those of the monoolefins.

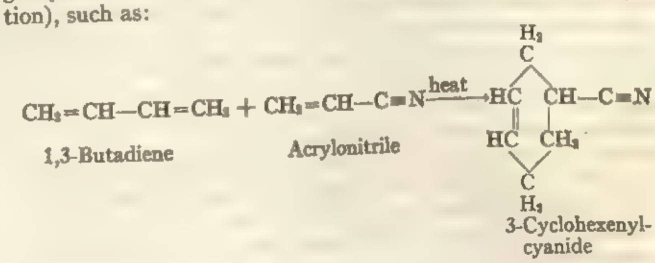
When the addition reaction to conjugated diolefins is carried out stepwise, the addenda are often attached to the first and fourth carbon atoms of the conjugated system rather than to adjacent carbon atoms; such a reaction as this is called 1,4-addition.

$$\underset{\text{1,3-Butadiene}}{CH_2=CH-CH=CH_2} + Br_2 \longrightarrow \underset{\text{1,4-Dibromo-2-butene}}{BrCH_2-CH=CH-CH_2Br}$$

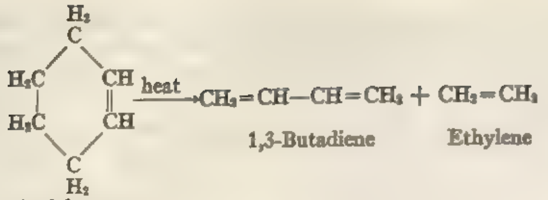
The conjugated dienes react with compounds containing the

$$>C=C< \quad \text{(particularly } >C=C-\overset{|}{C}=O,\ >C=C-C\equiv N, \text{ etc.)}$$

group with the formation of cyclic compounds (Diels-Alder reaction), such as:



1,3-Butadiene ($CH_2=CH-CH=CH_2$) melts at $-108.7°$ C., boils at $-4.5°$ C.; it can be obtained in the laboratory by cracking cyclohexene,



Cyclohexene 1,3-Butadiene Ethylene

by dehydration of 1,3-butene glycol,

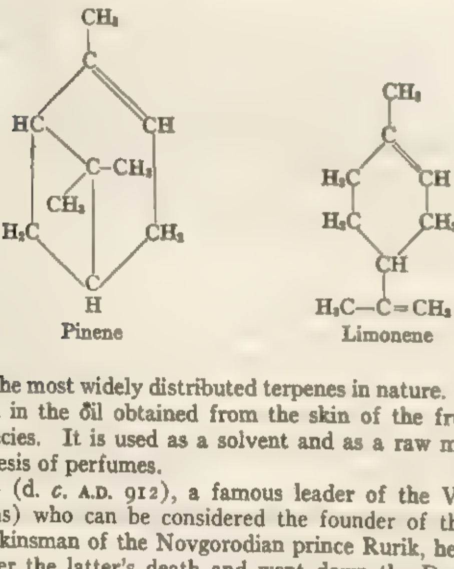
$$HOCH_2-CH_2-CHOH-CH_3 \xrightarrow{Al_2O_3} CH_2=CH-CH=CH_2 + 2H_2O$$

1,3-Butene glycol 1,3-Butadiene

Butadiene is prepared commercially by dehydrogenation of normal butenes. During World War II a substantial amount of butadiene was also produced by catalytic treatment of ethyl alcohol. Butadiene in conjunction with styrene is the main component in the manufacture of synthetic rubber. (*See* also BUTADIENE.)

Isoprene (2-Methyl-1,3-butadiene) ($CH_2=C(CH_3)-CH=CH_2$) melts at $-146.8°$ C., boils at $34.1°$ C., d_4^{20} 0.6805. It is a building unit for naturally occurring products such as rubber and terpenes; these products, on pyrolysis, yield isoprene. Isoprene changes into rubberlike compounds when heated under pressure, or when treated with sodium or peroxides.

Cyclic Olefins.—Of the cyclic olefins, those belonging to the class of terpenes (*q.v.*) with the formula $C_{10}H_{16}$ are the most abundant in nature. They are divided into (*a*) bicyclic monoolefins (bicyclic monoterpenes), of which pinene, the main constituent of turpentine oil, is the most important representative; (*b*) monocyclic diolefins (monocyclic monoterpenes), of which limonene



Pinene Limonene

is one of the most widely distributed terpenes in nature. Limonene is present in the oil obtained from the skin of the fruits of the citrus species. It is used as a solvent and as a raw material for the synthesis of perfumes. (H. Ps.)

OLEG (d. *c.* A.D. 912), a famous leader of the Vikings (or Varangians) who can be considered the founder of the Russian state. A kinsman of the Novgorodian prince Rurik, he left Novgorod after the latter's death and went down the Dnieper river with his Varangian retinue, seizing Smolensk and Kiev.

Having made Kiev his capital, Oleg expanded his authority both west and east of the great Volkhov-Dnieper waterway, uniting the local Slavic and Finnish tribes under his rule, and became the undisputed ruler of the great Kievan-Novgorodian state. He defeated the Khazars and delivered several Slavic tribes from dependence on them. Turning his attention southward, he undertook a well prepared expedition against Constantinople (*c.* 905) and forced the Byzantine government to sue for peace and to pay a large indemnity. In 907 his plenipotentiaries in Constantinople concluded a trade agreement with the imperial government; and in 911 a new treaty was concluded regulating commercial relations between the two states and providing for the legal protection of foreign merchants.

As a result of Oleg's military and diplomatic successes, trade with Byzantium became a permanent factor in Kievan Russia's economic life.

See *The Russian Primary Chronicle*, Eng. trans. by S. H. Cross and O. P. Sherbowitz-Wetzor (1953); G. Vernadsky, *The Origins of Russia* (1959). (S. G. Pu.)

OLEIC ACID is the most widely distributed of all the fatty acids (*see* CARBOXYLIC ACIDS) and apparently occurs to some extent in all oils and fats. In oils such as olive, palm, peanut and sunflower-seed it is the principal acid obtained by saponification. Oleic acid, $CH_3(CH_2)_7CH=CH(CH_2)_7CO_2H$, like other fatty acids, does not occur in the free state but is normally found as an ester of glycerol; *i.e.*, as a glyceride or as an ester of a long-chain alcohol.

Oleic acid I Elaidic acid II

Oleic acid is a solid with a low melting point; two crystalline forms (α-form, melting point 13.4° C. and β-form, melting point 16.3° C.) are known. It is a long-chain carboxylic acid; its molecule contains one double bond between C_9 and C_{10} with the cis configuration. The structure of oleic acid (I) may be deduced from the following reactions. Treatment with selenium or oxides of nitrogen partially transforms it into the trans-isomer, elaidic acid (II). The arrangement of its 18 carbon atoms and the position of the double bond is demonstrated by its catalytic hydrogenation to stearic acid, $CH_3(CH_2)_{16}CO_2H$; its oxidative cleavage to nonanoic (pelargonic) acid, $CH_3(CH_2)_7CO_2H$, and azelaic acid, $HO_2C(CH_2)_7CO_2H$. When oleic acid is heated with alkali, migration of the double bond occurs giving the $\alpha{:}\beta$-unsaturated acid, $CH_3(CH_2)_{14}CH=CHCO_2H$, and this on further heating with alkali gives palmitic acid, $CH_3(CH_2)_{14}CO_2H$.

Oleic acid shows the standard reactions of a carboxylic acid and a disubstituted ethylene, including the formation of a dibromide with bromine and a glycol with dilute aqueous potassium permanganate.

See K. S. Markley, *Fatty Acids, Their Chemistry and Physical Properties* (1947); A. E. Bailey, *Industrial Oil and Fat Products* (1945). (W. D. Os.)

OLEN, a legendary poet and prophet, reputed author of certain hymns to Apollo, sung at Delos in historical times. Boio, a Delphic poetess, portrayed him as a Hyperborean (*see* HYPERBOREANS), founder of the oracular shrine at Delphi, first prophet there and inventor of the hexameter. Herodotus made him a Lycian (as follower of Apollo Lukeios). Whether any real person lies behind these stories is unknown.

OLEOMARGARINE: *see* MARGARINE.

OLÉRON, ÎLE D', an island located in the Bay of Biscay, off the west coast of France north of the Gironde estuary and in Charente-Maritime *département*. Pop. (1954) 13,901. It is about 100 sq.mi. in extent, and is aligned northwest-southeast for about 20 mi. The Pertuis de Maumusson, separating it from the mainland, narrows to less than one mile. The limestone basis of Oléron outcrops to form cliffs on the north, but most of the island is flat and bordered by dunes within a fringe of reefs and enclosing extensive marshes. Oyster culture is practised along the southeast coast. Le Château d'Oléron, the chief port, facing the mainland, is surrounded by 17th-century fortifications. Five miles farther south is the resort, St. Trojan-les-Bains. Another bathing resort is St. Denis, and in the centre of the island is the market town, St. Pierre (pop. [1962] 1,423). Oléron, called Uliarus Insula by the Romans, formed part of the duchy of Aquitaine and passed to the French crown in 1370. It gave its name to the medieval maritime code, *Jugements ou Rôles d'Oléron*, which formed the basis of subsequent French naval statutes. (AR. E. S.)

OLEŚNICKI, ZBIGNIEW (1389–1455), Polish cardinal and statesman who exercised great influence under the first two kings of the Jagiello dynasty, was born at Sienno, near Sandomierz, of the family of the lords Dębno of Oleśnica. Starting his political career in the royal chancellery, he was acting as King Wladyslaw II Jagiello's secretary during the battle of Grunwald in 1410, when

he saved the king from a direct onslaught. Having visited Rome in 1411, he chose priesthood in 1412 and became bishop of Cracow in 1423. A member of the king's council, he led the conservative wing of the nobility and in 1430 secured a limitation of the royal power in return for the Poles' recognition of the child Wladyslaw III) as his father's eventual successor. Meanwhile, as an opponent of the Hussite movement in Poland, he promoted the interests of the papacy and the designs of Sigismund of Luxembourg, king of Hungary and German king, on Bohemia. On the other hand he wanted the incorporation of Lithuania into Poland and so opposed Sigismund when the latter proposed a royal crown for the Lithuanian prince Vytautas (1429). After Wladyslaw II Jagiello's death (1434) Oleśnicki virtually ruled Poland: he crushed the pro-Hussite movement led by Spytko of Melsztyn (1439) and acquired the duchy of Siewierz for his own bishopric (1443). He supported the Council of Basel against Pope Eugenius IV, though Eugenius created him cardinal in 1439.

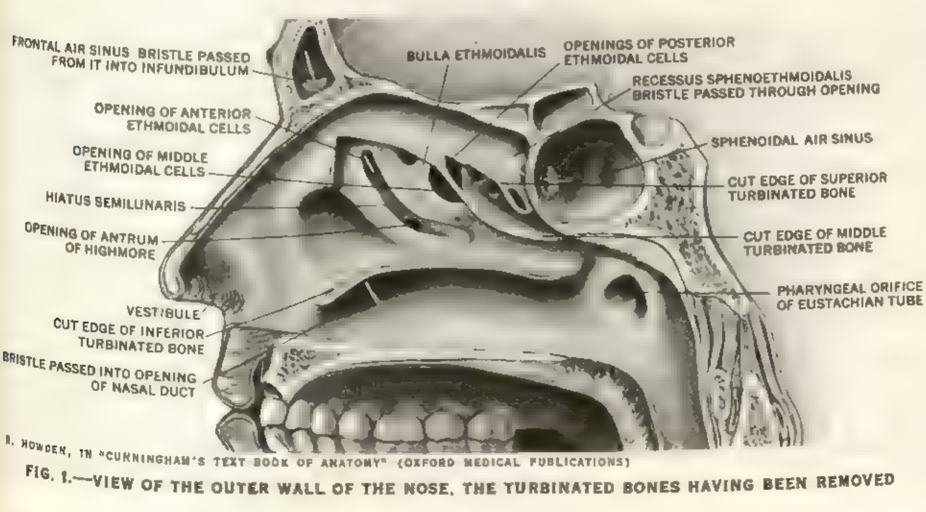
When Wladyslaw III (Ulászló I of Hungary from 1440) was killed on his crusade in 1444, Oleśnicki continued in power till Casimir IV received the Polish crown in 1447. Casimir organized the group of "young barons of the realm" to oppose him and, against his advice, achieved the incorporation of Prussia into Poland (1454). Oleśnicki, who had at last received his cardinal's hat from Pope Nicholas V in 1449, died at Sandomierz on April 1, 1455. (A. Gi.)

OLFACTORY SYSTEM, the structures that serve the sense of smell. The system consists of the nose and the nasal cavities, which in their upper parts support the olfactory mucous membrane for the perception of smell, and in their lower parts act as respiratory passages. This article deals with the anatomy of the olfactory system and its nervous pathways; for physiology, *see* SMELL AND TASTE.

The bony framework of the nose is part of the skull (*q.v.*), but the outer nose is supported only by bone above; lower down its shape is kept by cartilaginous plates. The expanded lower part of the side of the nose, the ala, is formed only of skin, both externally and internally, with fibrofatty tissue between the layers. The nasal cavities are separated by a septum covered in its lower two-thirds by thick, highly vascular mucous membrane composed of columnar ciliated epithelium with masses of acinous glands embedded in it, while in its upper part it is covered by the less vascular but more specialized olfactory membrane. Near the front of the lower part of the septum a slight opening into a short blind tube, which runs upward and backward, may sometimes be found; this is the vestigial remnant of Jacobson's organ. The supporting framework of the septum is made up of ethmoid above, vomer below and the septal cartilage in front. The outer wall of each nasal cavity is divided into three meatuses by the overhanging turbinated bones. Above the superior turbinated bone is a space between it and the roof known as the recessus sphenoethmoidalis, into the back of which the sphenoidal air sinus opens. Between the superior and middle turbinated bones is the superior meatus, containing the openings of the posterior ethmoidal air cells, while between the middle and inferior turbinated bones is the middle meatus, which is the largest of the three and contains a rounded elevation, the bulla ethmoidalis. Above and behind this is often an opening for the middle ethmoidal cells; below and in front runs a deep sickle-shaped gutter, the hiatus semilunaris, which communicates above with the frontal air sinus and below with the opening into the antrum of Highmore or maxillary antrum. The inferior meatus is below the inferior turbinated bone, and, when that is lifted, the valvular opening of the nasal duct (*see* EYE, HUMAN) is seen. The roof of the nose is narrow, and here the olfactory nerves pass in through the cribriform plate. The floor is wider so that a coronal section through each nasal cavity has roughly the appearance of a right-angled triangle.

Embryology.—In the third week of intrauterine life two nasal pits appear on the under side of the front of the head; they are the first appearance of the true olfactory region of the nose, and some of their epithelial lining cells send off axons (*see* NERVOUS SYSTEM: *Nerve Cells*) which arborize with the dendrites of the cells of the olfactory lobe of the brain and so form the olfactory nerves. Between the olfactory pits the broad median frontonasal process grows down from the forehead region to form the dorsum of the nose (*see* fig. 2) and the anterior part of the nasal septum, while outside them the lateral nasal processes grow down and later on meet the maxillary processes from the first visceral arch. In this way the nasal cavities are formed, but are separated from the mouth by a thin bucconasal membrane which eventually is broken through; after this the mouth and nose are one cavity until the formation of the palate in the third month. In the third month Jacobson's organ may be seen as a well-marked tube lined with respiratory mucous membrane; no explanation of the function of Jacobson's organ in man is known, and it is probably entirely atavistic. At birth the nasal cavities are shallow from above downward, but rapidly deepen till the age of puberty.

Comparative Anatomy.—In the lancelet there is a ciliated pit above the anterior end of the central nervous system, which is probably a rudiment of an unpaired olfactory organ. In the Cyclostomata (lampreys and hags) the pit is at first ventral, but later becomes dorsal and shares a common opening with the pituitary invagination. It furthermore becomes divided internally into two lateral halves. In fishes there are also two lateral pits, the nostrils of which open sometimes, as in the sharks and rays, onto the ventral surface of the snout, and sometimes, as in the higher fishes, onto the dorsal surface. Up to this stage the olfactory organs are mere pits, but in the Dipnoi (mudfish) an opening is established from them into the front of the roof of the mouth, and so they serve as respiratory passages and organs for the sense of smell. In the higher Amphibia the nasal organ becomes included in the skull and respiratory and olfactory parts are distinguished. In this class, too, turbinal ingrowths are found, and the nasolachrymal duct appears.



FROM R. HOWDEN, IN "CUNNINGHAM'S TEXT BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 1.—VIEW OF THE OUTER WALL OF THE NOSE, THE TURBINATED BONES HAVING BEEN REMOVED

In the lizards, among the Reptilia, the olfactory and respiratory parts are very distinct, the latter being lined only by stratified epithelium unconnected with the olfactory nerves. There is one true turbinal bone growing from the outer wall, and close to this is a large nasal gland. In crocodiles the hard palate is formed, and there is henceforward a considerable distance between the openings of the external and internal nares. In crocodiles, also, air sinuses are first found extending from the olfactory cavities into the skull bones.

The birds' arrangement is very like that of the reptiles; olfactory and respiratory chambers

FIG. 2.—VIEWS OF THE DEVELOPMENT OF HUMAN EMBRYONIC HEADS

A. Side view of the head of human embryo about 27 days old, showing olfactory pit and visceral arches and clefts. B. Transverse section through head of an embryo, showing relation of olfactory pits to forebrain and to roof of stomodaeal space. C. Head of human embryo about 29 days old, showing division of lower part of mesial frontal process into two globular processes. D. Transverse section of embryo head, showing deepening of olfactory pits and their relation to hemisphere vesicles of forebrain

are present, and into the latter projects the true turbinal, though there is a pseudoturbinal in the upper or olfactory chamber. In mammals the olfactory chamber of the nose is variously developed; most of them are macrosmatic, and have a large area of olfactory mucous membrane; some, like the seals, whalebone whales, monkeys and man, are microsmatic, while the toothed whales have the olfactory region practically suppressed in the adult, and are said to be anosmatic. There are generally five turbinal bones in macrosmatic mammals, so that man has a reduced number. The lowest of the series, the maxilloturbinal, is the equivalent of the single true turbinal bone of birds and reptiles, and in most mammals is a double scroll, one leaf turning upward and the other down.

Jacobson's organ first appears in amphibians, where it is found as an anteroposterior gutter in the floor of the nasal cavity. In reptiles the roof of the gutter closes in on each side, and a tube is formed lying below and internal to the nasal cavity, opening anteriorly into the mouth and ending by a blind extremity, posteriorly to which branches of the olfactory and trigeminal nerves are distributed. In the higher reptiles (crocodiles and chelonians) the organ is suppressed in the adult, and the same applies to birds; but in the lower mammals, especially the monotremes it is very well developed, and is enclosed in a cartilaginous sheath from which a turbinal process projects into its interior. In other mammals, with the exception of the Primates and perhaps the Chiroptera, the organ is quite distinct, though even in man, as has been shown, its presence can be demonstrated in the embryo.

(F. G. P.; P. N.)

Nervous Pathways of Smell.—The pathway of olfactory conduction begins with the olfactory receptors—small, slender nerve cells embedded in large numbers (about 100,000,000 in the rabbit) in the epithelium of the mucous membrane lining the upper part of the nasal cavity. Each olfactory receptor cell emits two processes (projections). One of these is a short peripheral dendrite, which reaches to the surface of the epithelium where it ends in a knob carrying a number of fine, radially placed filaments, the olfactory hairs. The other process is a long and extremely thin axon, the olfactory nerve fibre, which reaches the cranial cavity by passing through one of the openings in the bony roof of the nasal cavity and enters the olfactory bulb of the forebrain (fig. 3). Sensations of smell are experienced when certain chemical substances become dissolved in the thin layer of fluid covering the surface of the mucous membrane, and thus come in contact with

FIG. 3.—BASAL ASPECT OF THE BRAIN OF THE (A) RAT, (B) CAT AND (C) MONKEY

Olfactory structures on the right side of each drawing are indicated by shading; on the left they are numbered as follows: (1) olfactory bulb; (2) olfactory tract; (3) cortex of the pyriform lobe; (4) olfactory tubercle. The broken circle indicates the position of the amygdaloid complex, which is covered by the cortex of the pyriform lobe. (The three brains have not been drawn on the same scale)

the olfactory hairs. In all probability it will be found that the receptor cells differ among themselves in their sensitivities to various odorous substances.

In the olfactory bulb, the olfactory nerve fibres end in contact with the antenna-shaped dendrites of the large mitral cells, which represent the second main link in the chain of olfactory conduction. Each mitral cell emits a long axon, many of which enter into the formation of the olfactory tract, a white fibre band extending back from the bulb over the basal surface of the forebrain (fig. 3). The olfactory tract distributes its fibres mainly to the cortex of the pyriform lobe, which constitutes the final cortical receiving area of the olfactory pathway. In man, this region corresponds to the uncus of the hippocampal gyrus. A smaller number of fibres of the olfactory tract end in two further olfactory structures; viz., the olfactory tubercle and the medial part of the amygdaloid complex (the latter lies deep to the olfactory cortex; fig. 3).

In mammals with a highly developed sense of smell (macrosmatic mammals), such as the rodents and carnivores, the olfactory brain structures are relatively large and occupy all or a large part of the basal surface of the forebrain (fig. 3A and B). A marked reduction of all olfactory structures is evident in the microsmatic primates (monkeys, apes and man; fig. 3C), which for their orientation rely more heavily upon the senses of vision and touch. (W. J. H. N.)

OLGA, SAINT (d. A.D. 969), Kievan princess, regent of the grand principality of Kiev from 945 to 964. She was the widow of Prince Igor, who was killed in 945 by the rebellious Drevlyane tribe after an attempt to extort excessive tribute. As Igor's son Svyatoslav was still a minor, Olga became the actual ruler of Kievan Russia, governing the country with a strong and skilful hand. She severely punished the Drevlyane for their crime and took measures to regulate the collection of tribute and to safeguard the security of the state. Olga was the first of the Kievan princely house to adopt the "Greek faith," namely Orthodox Christianity, being baptized *c.* 955; and she subsequently visited Constantinople. The *Primary Russian Chronicle* eulogized her as the precursor of Russian Christianity, "as daybreak precedes the sun and as the dawn precedes the day; for she shone like the moon by night, and she was radiant among the infidels like a pearl in the mire." Olga's memory was greatly venerated in Russia, and she was later canonized as the first Russian saint of the Orthodox Church. (S. G. Pu.)

OLIER, JEAN JACQUES (1608–1657), founder of the Sulpicians and spiritual writer, one of the chief architects of the religious renewal of 17th-century France, was born at Paris on Sept. 20, 1608. Destined by his mother for an ecclesiastical career and at 18 already prior of two monasteries and abbot of a third, he gave himself to a life of pleasure when his theological training at the Sorbonne was over. He was converted in 1631 and went to Rome for further studies. He returned to Paris the following year after having been cured at Loreto of a serious eye ailment and devoted himself wholly to the care and instruction of the poor of the city and to preaching throughout the rural districts. Ordained priest in 1633, he came under the influence of St. Vincent de Paul and Charles de Condren and in 1641 established a seminary for the training of future priests at Vaugirard. The year following he was made pastor of the sprawling, disorganized parish of St. Sulpice in Paris. Thither he transported his seminary and made it and the parish models that would be imitated widely. His writings, in the tradition of Pierre de Bérulle (*q.v.*), are chiefly concerned with the spiritual implications of the Christian priesthood. He died April 2, 1657.

Olier's *Oeuvres complètes* were edited by J. P. Migne (1856).

BIBLIOGRAPHY.—The standard life is that by E. M. Faillon, 4th ed., 3 vol. (1873). *See* also P. Pourrat, *Christian Spirituality*, vol. iii, pp. 352–386 (1927); H. Bremond, *Histoire littéraire du sentiment religieuse en France*, vol. iii, pp. 420–507 (1929). (E. O'B.)

OLIGARCHY is the traditional term used to denote the rule of the few when that rule is looked upon with disfavour. Aristotle used it to designate the rule of the few when it was exercised not by the best, but by bad men unjustly. In this sense, it overlaps with the later concept of plutocracy.

It is a recurrent idea that all forms of government are in the final analysis reducible to the rule of a few. Oligarchs will secure effective control whether the formal authority is vested in the people, a monarch, the proletariat or a dictator. Thus, Karl Marx and Friedrich Engels insisted that throughout capitalism, the key capitalists had controlled the government; they coined the famous phrase, "the state is the executive committee of the exploiting class." The Italian political scientist Gaetano Mosca likewise insisted that a "ruling class" always constituted the effective oligarchical control. Vilfredo Pareto elaborated the idea in his doctrine of the "elite." The modern tendency to analyze social patterns in terms of an "elite," although greatly reinforced by Pareto's theory, goes further back than Marx and Engels, who employed the term "elite" to describe the class-conscious communists, the leading group within the proletariat. To say that all governments are in essence oligarchical may be an exaggeration. Yet a tendency persists in all organizations to evolve a limited group at the centre who, as insiders, "run the show." Political science and sociology are beginning to differentiate more carefully between various types of control and power. The type of power held by a democratic party boss, while overwhelming in relation to any single member of the party, is very different from that wielded by the boss of the single party in a totalitarian and authoritarian pattern. Likewise, the control group within an organization does not occupy the same position under democratic conditions (which provide for the group's being effectively challenged by outsiders at any time) as it does under an authoritarian plan. If effective control changes hands as rapidly as it does in a city of the U.S. or a British trade union, it is doubtful that those exercising it should be spoken of as a "class" or an "elite." The expression "the few" is too abstract to tell us much. Like the other purely numerical concepts of government inherited from Greek philosophy, oligarchy is an outmoded term, because it fails to direct attention to what we really wish to know about a government. (C. J. Fr.)

OLIGOCENE, in geology, is the third epoch of the Tertiary period. The name is derived from the Greek *oligos*, "few," and *kainos*, "recent," in reference to the relatively small percentage (about 10%) of living shellfish found as fossils. The Oligocene is the time interval between the older Eocene and the younger Miocene and the Oligocene series includes the rocks formed during this interval. In those classifications in which it includes the European stages Tongrian, Rupelian and Chattian, it is generally estimated to have a time duration of about 11,000,000 years. The interval was originally included by Sir Charles Lyell in his Older Miocene. The term Oligocene was proposed by H. E. Beyrich in 1854 and again in 1858, being based on rocks in north Germany and their contained fauna. The Oligocene is thus the youngest division of the older, and the middle division of the revised Tertiary (*q.v.*) as indicated on the accompanying geologic time chart.

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	Began (Millions of Years Ago)
		CENOZOIC ERA	
Quaternary	Recent (last 11,000 years)		
	Pleistocene	Early man	2+
Tertiary	Pliocene	Large carnivores	10
	Miocene	Whales, apes, grazing forms	27
	Oligocene	Large browsing mammals	38
	Eocene	Rise of flowering plants	55
	Paleocene	First placental mammals	65–70
		MESOZOIC ERA	
Cretaceous		Extinction of dinosaurs	130
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	180
Triassic		Appearance of dinosaurs	225
		PALEOZOIC ERA	
Permian		Reptiles developed, conifers abundant	260
Carboniferous			
Upper (Pennsylvanian)		First reptiles, coal forests	300
Lower (Mississippian)		Sharks abundant	340
Devonian		Amphibians appeared, fishes abundant	405
Silurian		Earliest land plants and animals	435
Ordovician		First primitive fishes	480
Cambrian		Marine invertebrates	550–570
		PRECAMBRIAN TIME	
		Few fossils	more than 3,490

LIFE OF THE EPOCH

The life of the epoch resembled that of the Eocene more than that of the succeeding Miocene.

Marine.—Foraminifera were abundant; nummulites were still numerous at first but of smaller size, becoming extinct by the close of the epoch. Corals, bryozoans and echinoids were abundant in clear waters of the middle and lower latitudes but were less widely distributed than previously. Shelled cephalopods were few but gastropods and pelecypods assumed more of their present importance.

Terrestrial.—On land the highly varied fauna was composed of a mixture of surviving archaic types and the beginnings of modern families. It is possible to recognize carnivores (Canidae and Felidae), insectivores, rodents, ruminants and camels. Fore-

runners of the modern rhinoceros, elephant and horse are recognizable. Giant herbivores such as the brontotheres (or titanotheres) were a spectacular element.

See also PALEONTOLOGY.

For the flora *see* PALEOBOTANY.

CONDITIONS DURING THE OLIGOCENE

Oligocene deposits are of freshwater, brackish, marine and terrestrial origins; they include sands, sandstones, grits, marls, shales, limestones, conglomerates, lignites and volcanic materials. The thickness varies from a few hundred feet, as in parts of France, to well over 10,000 ft. as in Oregon-Washington, northern South America and Burma. The deposits were mostly laid down in shallow water or on land, but in places, as in parts of Oregon-Washington, Colombia and Peru, the fossils indicate a deepwater marine environment of several hundreds to perhaps several thousands of feet in depth. Here and there, as in north Germany and the Lake Aral region in western Asia, the sea gained ground that had been unoccupied during the preceding Eocene, but in most areas the seas were less extensive than in the Eocene and the succeeding Miocene epoch. During the late Eocene and early Oligocene important diastrophic changes were in progress. In Europe the Pyrenees and parts of the Alps were uplifted at this time. In the early Oligocene the Bering sea land bridge was elevated, allowing a notable terrestrial faunal migration between the old and new worlds. Near the end of the epoch the ancient Tethys sea started to fragment and marine connections between the Mediterranean and the Indo-Pacific region were broken. In places, as in the Rocky mountains and parts of France, lacustrine or lake and terrestrial deposits were formed. There was extensive vulcanism in the high plains and Rocky mountain areas of the United States and in the northern Andes of South America.

OLIGOCENE STRATIGRAPHY

Neither the lower nor the upper limit of the Oligocene is well defined (*see* TERTIARY), but there is more general agreement on the placement of the boundary with the preceding Eocene than with the succeeding Miocene.

European Stages and Formations.—The epoch is more often considered to include (from oldest to youngest) the European stages identified as Tongrian (Lattorfian, Sannoisian), Rupelian (Stampian) and Chattian (Casselian), but there is little general agreement as to whether or not the Aquitanian stage is younger than, or in part equivalent to, the Chattian. Thus the Aquitanian may or may not be included in the Oligocene.

The Tongrian stage (from Tongres, Belg.) is represented by marine and freshwater clays and sands in Belgium, marine sandy glauconitic beds in northern Germany at Latdorf between Magdeburg and Leipzig and the famous series of supragypsiferous marls (Sannoisian) of the Paris basin. At the base of the Sannoisian are blue marls, deposited in salt lagoons, then white marls with freshwater horizons and finally widely distributed green marine marls. Contemporaneous marine sands and clays in northern Germany were called Lattorfian. In Britain, classic exposures of Lower Oligocene sediments occur on the Isle of Wight and have been described from base upward as Middle Headon beds (brackish and marine), Upper Headon beds (freshwater clays, marls and limestones) and Osborne and Bembridge beds (brackish and freshwater sands, clays and limestones).

The precise correlation of different members of the Tongrian stage in western Europe is still uncertain. Many geologists have considered the molluscan and echinoid faunas of these beds as closely allied to those of the uppermost Eocene of the Paris basin.

The Rupelian stage (from Rupel, a tributary of the Scheldt in Belgium) is the most widely distributed and easily recognized unit of the Oligocene in western Europe. It is represented in Belgium by a thick series of clays, the *argiles de Boom*, and in the Paris basin by the *sables de Fontainebleau* and the underlying Brie limestone (sometimes termed the Stampian). Marine sandstones of equivalent age, called the Septarienton, occur in the Mainz basin and in northern Germany, where they were deposited in a transgressing sea. The Hampstead beds in the Isle of Wight, which consist of marine to brackish clays and marls, were deposited during early Rupelian time.

The Chattian stage (from Chattes, an ancient tribe which lived near Kassel, Ger.) is represented in the Mainz basin and northern Germany by glauconitic marine sands and overlying brackish and freshwater marls and limestones. Equivalent beds are unknown in Britain and Belgium. After the deposition of the Fontainebleau sands the sea left the Paris basin, and its area was occupied by a huge lake within which accumulated the Étampes limestone of which the *meulière de Montmorency* is a lateral equivalent. Above these beds lie the freshwater Beauce limestones, which in part belong to the Aquitanian stage. Continental Oligocene beds are found in several basins of the central European continent.

Marine and continental Oligocene deposits occur in the Alpine geosyncline of southern and eastern Europe and the Aral-Caspian region. Deposits of the Tethyan seaway, characterized by tropical faunas with nummulites and *Lepidocyclina*, extend from the western Mediterranean to India and even the East Indian region.

Western Hemisphere Correlations and Formations.—Exact correlation of marine Oligocene deposits of the new world with those of western Europe is difficult because of provincial faunas. Marine sediments occur in the Gulf and Atlantic coastal plains of the United States, in eastern Mexico, Central America, the West Indies, the northern third of Venezuela and Colombia and in western Ecuador and northwestern Peru. Thick deposits occur in the Coast ranges of California, Oregon, Washington and in southern Alaska and northeastern Asia.

In the eastern United States lower Oligocene sediments occur only in Mississippi and Alabama and are represented by the thin deltaic Forest Hill sand and the Red Bluff clay. Superposed are light-coloured shaly marls and clays of the Vicksburg group. They were deposited during the Middle Oligocene in a widely transgressing sea which extended at times from South Carolina to the coastal plain of Mexico. A slight subsidence of the sea floor during Late Oligocene time was followed by deposition of nearly 100 ft. of the Flint River and Suwannee limestones from South Carolina to northern Florida and by the Chickasawhay marls and shales from Alabama to the Mississippi river. No sediments of Upper Chattian age are exposed unless the sandstones of the lower part of the Catahoula formation extend down into the Oligocene. This formation is thought to have been deposited during the Aquitanian, which is variously included in either the Oligocene or the Miocene (see *European Stages and Formations*, above). Marine limestones and shales of Oligocene age are widely distributed in the West Indies, Costa Rica and Panamá.

Marine Oligocene sediments of diverse character occur in northern Venezuela and Colombia. They are mainly blue, brown and gray shales, interbedded sandy shales and sandstones and thick massive sandstones which were deposited in a slowly subsiding trough. These deposits range from 5,000 to 10,000 ft. thick and have been named the Mugrosa, Colorado and Poso series in Colombia and the El Fausto, Icotea, Churuguara, San Luis, Agua Clara, Agua Salada and Carapita formations in Venezuela. The Agua Clara formation is the best known and consists of more than 2,500 ft. of lagoonal gypsiferous shales with marine intercalations. Near the end of the Oligocene the seaway briefly extended south along the eastern front of the Andes in Venezuela, Colombia and Ecuador. These marine deposits are intercalated in the midst of thick continental and lacustrine detrital sediments.

Several thousand feet of marine sandstones and shales occur in the coastal part of northwest Peru and extend through western Ecuador to Colombia. They accumulated in a trough which seemingly connected the Caribbean sea with the Pacific ocean.

During the Oligocene an area more than 100 mi. wide in western North America, extending from Vancouver Island to middle Oregon and in California from San Francisco bay to the Transverse ranges was largely occupied by marine embayments.

In Oregon and Washington over 10,000 ft. of marine shale, sandstone, and conglomerate have been classified from top downward as the Blakeley, Lincoln and Keasey formations. Faunal zones (*see* FOSSIL) based on mollusks and foraminifera have been recognized within these deposits but it is uncertain how much of

the Keasey formation extends down into the Eocene and how much of the Upper Blakeley formation ranges into the Miocene. In central California the Oligocene is represented by marine sandstones, sandy shales and deposits of volcanic tuff. In the San Joaquin valley there are deposits of massive and stratified light-gray shale and sand called the Tumey sand and Tumey shale. Other basins in southern California received thick accumulations of terrestrial and lacustrine conglomerate, sandstone and shale which were named the Sespe formation. Locally this formation ranges in age from Upper Eocene to Lower Miocene.

Land-laid deposits of Oligocene age occur throughout much of the Rocky mountains and adjacent areas of the United States. In the eastern Rocky mountains they are represented by the Wind River series, in Montana by the Pipestone Springs and Cook Ranch formations and in Oregon by the lower John Day formation.

Sandstones and shales containing marine fossils similar to those of the Blakeley formation occur in southern Alaska, Sakhalin Island, Kamchatka and in the northern island of Japan (Poronai formation).

New Zealand.—In New Zealand the marine deposits referred to the Oligocene are known as the Kaiatean, Whaingaroan (the two may be combined into the Ototaran), Duntroonian and Waitakian stages. The sediments of this age include mudstones, sandstones, limestones and marls, and attain a thickness of over 3,000 ft.

Woodford, pp. 467–553 (1956); Raymond C. Moore, *Introduction to Historical Geology*, 2nd ed., pp. 432–55, 527–552 (1958). (J. W. D.)

OLIGOCHAETA, a class of annelid worms, comprising the earthworms and small mud-living or aquatic, rarely marine or parasitic, species, most of which have several pairs of small bristles on each body segment. *See* Annelida.

OLIGOCLASE: *see* Feldspar.

OLIMPO, the northernmost of the three departments which make up the Paraguayan Chaco, is a region of scrub forest and grassland on a sandy and often swampy plain sloping eastward to the Paraguay river. For 150 mi. it is adjacent to Bolivia, from which it is separated by an artificial boundary. The population numbered 3,362 in 1962, consisting principally of Indians, cattle herders and lumberers producing quebracho wood. Large areas are almost uninhabited, and most people live in or near the capital, Olimpo, a port on the Paraguay river. This city is a strategic outpost and the only trading centre serving the needs of the department. (G. J. B.)

OLINDA, a city of the northeastern state of Pernambuco, Braz., located on a low hill on the Atlantic coast, about 7 mi. N. of the port city of Recife. Pop. (1960) 100,545. Olinda is noted principally for its ornate churches and monasteries, which date from the 16th and 17th centuries, and other buildings of historical interest. It was founded as the colonial capital in 1537 by Duarte Coelho Pereira. By 1600 an economy based upon sugar and Negro slave labour had made it a feudal and ecclesiastical stronghold. In 1630 the Dutch captured Olinda and occupied and retained control of Pernambuco until 1654. By that time the city had entered an era of decadence and its place of leadership had passed to Recife which became the capital. The Olinda seminary, founded in 1800 by Bishop José Azeredo Coutinho, won recognition for the liberal thinkers it graduated before independence was achieved. (J. J. J.)

OLIPHANT, LAURENCE (1829–1888), British author, traveler and mystic, one of the most paradoxical figures in Victorian society, was born in Cape Town, South Africa, in 1829, his father being at that time attorney general in Cape Colony. His education was desultory; he was called to the bar but soon gave up the law. Before the age of 24 his travels had provided material for two books, *A Journey to Khatmandu* (1852) and *The Russian Shores of the Black Sea in the Autumn of 1852, and a Tour Through the Country of the Don Cossacks* (1853). Later experiences in various parts of the world, as secretary to Lord Elgin, war correspondent of the *Times*, unofficial British observer and (briefly) first secretary of the British legation in Japan, are recorded with verve in *Episodes in a Life of Adventure* (1887) and other books, one of which, the *Narrative of the Earl of Elgin's Mission to China and Japan* (1859), gives a fascinating account of 19th-century gunboat diplomacy. In 1865 appeared his satirical novel of London society, *Piccadilly: a Fragment of Contemporary Biography*, and in the same year he became Conservative member of parliament for the Stirling burghs.

In 1867 Oliphant went to the U.S. and joined the Brotherhood of the New Life, first at Amenia, and then at Brocton, N.Y., founded by the spiritualist "prophet" T. L. Harris, to whose rule he submitted until 1881. In 1878 he had proposed to Disraeli and Lord Salisbury a plan for the Jewish colonization of Palestine (not Jewish himself, he appears to have been largely politically motivated), and in 1882 he and his wife settled in Haifa, where they formed a small community and wrote together the esoteric *Sympneumata: Evolutionary Forces Now Active in Man* (1884)—apparently a plea for purified sex life. Oliphant also wrote *Altiora peto* (1883), which has been compared with the novels of Aldous Huxley. He died at Twickenham on Dec. 23, 1888.

Bibliography.—Philip Henderson, *The Life of Laurence Oliphant* (1956); H. W. Schneider and G. Lawton, *A Prophet and a Pilgrim* (1942); Rosamond Dale Owen (Oliphant's second wife), *My Perilous Life in Palestine* (1928).

OLIPHANT, MARGARET OLIPHANT (1828–1897), prolific Scottish novelist, historical writer and biographer, best known for her portraits of small-town life, was born in Wallyford, Midlothian, on April 4, 1828. In 1852 she married her cousin, Francis Wilson Oliphant, and settled in London. Widowed in 1859, her life became a wearisome struggle to provide, by writing, for her children and later, for her brother's children. Between 1849 and her death she published more than 100 separate books, of which the best known are the *Chronicles of Carlingford*, published anonymously 1863–76. These four novels of contemporary life in a small town include *Miss Majoribanks* (1866), a young lady's attempts at social climbing, and *Salem Chapel* (1863), a young, intelligent nonconformist minister's trials with his narrow-minded congregation. The best of her Scottish novels are *Passages in the Life of Mrs. Margaret Maitland* (1849), *Merkland* (1851) and *Kirsteen* (1890). *A Beleaguered City* (1880) and *A Little Pilgrim in the Unseen* (1882) introduce the supernatural. She also published historical studies, children's books, biographies, and *Annals of a Publishing House: William Blackwood and His Sons* (1897), a work of importance to literary historians. She wrote with sympathy, insight and humour about domestic life, but although she was often compared with George Eliot, she lacked the latter's intellectual fibre. She died at Windsor on June 25, 1897.

See *Autobiography and Letters*, ed. by Mrs. H. Coghill (1899).

OLIVARES, GASPAR DE GUZMÁN, Conde-Duque de (1587–1645), Spanish statesman who for nearly 22 years ruled the country as King Philip IV's favourite, was born on Jan. 6, 1587, in Rome, where his father, Enrique de Guzmán, 2nd conde de Olivares, was Philip II's ambassador to the Holy See till 1591. He succeeded to his father's title in 1607, during Philip III's reign, and, despite the jealousy of the duque de Lerma, won a dominant influence over the heir to the throne, who, on becoming king as Philip IV in March 1621, put him in charge of affairs. The rank of grandee having been attached to his countship in 1621, Olivares kept its name by styling himself conde-duque de Olivares after he was created duque de Sanlúcar (1625).

Energetic and accustomed to splendour, a patron of dramatists and the subject of brilliant portraits by Velázquez, Olivares was avid for power. Foreign policy, however, was in fact already predetermined from Philip II's time, and no minister could have dissuaded king, church and nation from pursuing the idea of Spanish hegemony in the Europe of the Counter-Reformation: so it was scarcely the fault of Olivares that Spain failed to renew the truce with the Dutch (1621; *see* Netherlands, The) and became involved in Italian conflicts and in that course of support for the Austrian Habsburgs in Germany which finally led to France's declaration of war in 1635 (*see* Thirty Years' War).

In domestic affairs he was more personally responsible for the catastrophes of the period: he overrode the rights of the autonomous regions of the monarchy and so provoked the revolts of the Catalans and of the Portuguese, which both began in 1640, as well as the abortive conspiracy of Francisco de Guzmán, marqués de Ayamonte, for a separate Andalusian kingdom (1641). Even so, his motive for authoritarian treatment of the regions was, partly at least, economic: he wanted them to provide supplies of money to offset the decline in imports of precious metals from America.

Under strong pressure from a court intrigue headed by the queen (Elizabeth of France), Philip IV dismissed his favourite in Jan. 1643. Olivares retired to Loeches and published an able counterblast to a memorandum by his enemies, but was soon ordered to proceed to distant Toro; and in Dec. 1644 the Inquisition began to investigate his conduct. He died at Toro on July 22, 1645.

BIBLIOGRAPHY.—M. Hume, *The Court of Philip IV*, 2nd ed. (1927); G. Marañón, *El Conde-Duque de Olivares*, 3rd ed. (1953); J. H. Elliott, *The Revolt of the Catalans* (1963).

OLIVE, a subtropical, broad-leaved evergreen tree (*Olea europaea*), grown for the production of its fruit, which is utilized for the extraction of olive oil (*q.v.*) and also for table olives. It is a member of the family Oleaceae, which also includes the privet, lilac, ash, forsythia and jasmine. The genus *Olea* contains about 30 other species, none bearing edible fruit, which are native to such parts of the world as South Africa, New Zealand, India and Afghanistan.

The edible olive, probably first collected wild in the eastern Mediterranean or south-central Asia region, is undoubtedly one of the world's oldest cultivated crops. There is evidence that the olive was grown on the island of Crete about 3500 B.C., and the Semitic peoples apparently cultivated it as early as 3000 B.C. (According to Scripture it was an olive leaf that Noah's dove took back to the ark.) Olive oil was a highly prized luxury for anointing the body in Greece during the time of Homer, about 900 B.C., and it was an important crop of the Romans around 600 B.C. In subsequent times olive growing spread to all the countries bordering the Mediterranean.

Plant Characteristics.—*Growth Form.*—The olive plant is a relatively slow-growing but long-lived evergreen tree, 10 to 40 ft. or more high. Branches are numerous and the tree, young or old, is very bushy. Strong, old trunks are deeply furrowed with ridges running from the branches to the roots, presenting a wide buttress at the base of the tree. The leaves, leathery and lance-shaped, are dark green above and silvery on the underside and are paired opposite each other on the twig. The wood is resistant to decay, and if the top dies back a new trunk will often arise from the roots. The tree is attractive, its beauty having been extolled for thousands of years. In ancient times it was a common feature of the landscapes of Palestine and parts of western Asia, as indicated by Scripture and Greek and Roman writings.

The trees bloom in late spring. Small, inconspicuous whitish flowers are borne in loose clusters in the axils of the leaves. Flowers are of two types: (1) perfect, containing both male and female parts, which are capable of developing into the olive fruits; and (2) male, or staminate, which contain only the male, pollen-producing parts. The olive is wind-pollinated, the presence of bees or other insects being unnecessary for fruit production.

Fruit-setting in the olive is often erratic; in some areas, especially where irrigation and fertilization are not practised, alternate bearing is the rule. The trees may set a heavy crop one year and not even bloom the next.

FRUITING BRANCH OF THE OLIVE (OLEA EUROPAEA)

BY COURTESY OF SPANISH TOURIST OFFICE

ONE OF THE FAMOUS 1,000-YEAR-OLD OLIVE TREES OF MAJORCA

The Fruit and Its Composition.—The olive fruit is classed botanically as a drupe, similar to the peach or plum. It consists of the skin (exocarp), the flesh (mesocarp) and the pit or stone (endocarp). Within the stone is found the seed, usually one, but sometimes two. Olives tend to have maximum oil content (about 20%–30% of fresh weight) and greatest weight six to eight months after the blossoms appear. At this time they are black, and will continue to cling to the tree for several weeks. Fruits for oil extraction are allowed to mature, but for processing as food immature fruits are handpicked or shaken off the tree.

Varieties.—There are literally hundreds of named varieties of both types of olives, table and oil, grown round the world in the warmer climates. In California olives are grown almost exclusively for table use. The Mission variety, which still ranks high in acreage planted, was selected from the seedlings first grown by the Franciscans in San Diego. Other table varieties introduced later from Europe include Ascolano (white olive of Ascoli) from Italy; Manzanillo and Sevillano from Spain; and Karydolia, Konservolia and Amygdalolia from Greece. In Europe olives are grown primarily for oil; among the varieties cultivated are Picual, Nevadillo, Chemali, Morcal, Oliviere, Leccino, Corregiolo, Zorzalino and Cornicabra.

Cultivation.—The tree will tolerate drought periods of five or six months through the summer, provided winter rainfalls of at least 8 to 10 in. occur. Olive trees will not survive temperatures below about 10° F. (−12° C.), being injured at 15° F. (about −9° C.). To form flowers and fruit the olive seems to require an exposure of several months to winter-chilling conditions. The tree itself will grow satisfactorily in tropical regions of the world but fails to bear fruit, probably because of a lack of winter chilling. Commercial olive production is generally found to occur in two belts around the world, one between 30° and 45° N. latitude, the other between 30° and 45° S. latitude. In these areas the necessary climatic requirements for vegetative growth and fruitfulness can be found.

Olive varieties do not come true from seed. Seedlings generally produce inferior fruit and must be budded or grafted to one of the named varieties. Olives also can be propagated by cuttings, either by hardwood cuttings set in the nursery row in the spring or by small leafy cuttings rooted under mist sprays in a propagating frame. Either type responds markedly to treatments with a root-promoting hormone.

The nursery trees are planted 25 to 35 ft. apart in irrigated orchards, or 40 to 75 ft. apart in unirrigated groves. They start bearing in 4 to 8 years, but full production is not reached until 15 or 20 years, or when dry-farmed, until the trees are 40 to 50 years old.

In the Mediterranean countries most olive groves are unirrigated. Although remarkably drought resistant, the olive will use just as much water as other trees if it is available. A general misconception is that olives require planting on poor, rocky hillside land and should be unirrigated. Although the olive plant will endure adverse conditions that would kill most other tree fruits, it responds markedly to irrigation, good soil and nitrogen fertilizers.

In California, where many groves are planted on some of the best orchard soils and carefully irrigated through the dry summers, yields of five to ten times those in the unirrigated orchards of the Mediterranean countries are obtained. In Spain, however, the general belief is that irrigated olives do not pickle as well as those dry-farmed and often the trees are not irrigated even when water is available.

Harvesting.—Harvesting of the fruit for pickling is done in

the autumn before the fruit turns black. Harvesting usually continues for about two months, or until the fruit becomes damaged by frost. Temperatures of 27° or 28° F. (about 2° to 3° C.) for several hours are likely to injure the tissues so the fruit cannot be used for pickling; such frozen fruits can be allowed to remain on the tree, however, to be harvested later for oil extraction. Table olive harvest is done by handpicking.

Olives to be harvested for oil extraction are allowed to remain on the tree until late winter when they turn black and reach their maximum oil content—20% to 30% of the fresh weight of the fruit (*see* OLIVE OIL). A common harvest practice, although undesirable, is to beat the trees with long poles, knocking the olives on to sheets spread on the ground under the tree. In many orchards, however, the fruit is handpicked even for oil extraction.

PRODUCTION AND PROCESSING

Production.—In the 20th century Spain became, by far, the leader in commercial olive production, accounting for about 38% of the world's olive production, followed by Italy with about 20% and Greece with about 13%. Other important olive-producing countries are Portugal, Turkey, Tunisia, France, Morocco, Algeria, Syria, Yugoslavia, Jordan, United States, Cyprus, Israel and Argentina. Europe, with nearly 500,000,000 olive trees, has more than three-quarters of the world's cultivated olives, followed by Asia (about 13%), Africa (8%) and America (3%).

Commercial olive production did not begin in the United States —where it is limited to California—until the latter part of the 19th century. The olive was earlier brought into California, however, from Mexico in 1769 by the Franciscan fathers. In South America and Australia, development of a commercial olive industry is even more recent, starting in the early part of the 20th century.

Olives are grown mainly for the production of olive oil. This is well illustrated in Spain where more than 90% of the crop is crushed annually for oil extraction.

The two leading producers of table olives are Greece and Spain, the former producing 35,000 tons in a good year and the latter 25,000 tons. Next in order of production are the United States (average 17,000 tons), Algeria (15,000), Argentina (12,600) and Italy (10,000).

Processing.—Fresh, unprocessed olives are inedible, as they are extremely bitter. This bitterness, due to a glucoside, can be neutralized by treatments with a dilute alkali such as lye (sodium hydroxide). Salt applications also dispel some of the bitterness.

Pickled Green Olives.—In the Mediterranean basin, and to some extent in California, the table olive crop is utilized for pickled green olives. For this the fruits are harvested before they begin to soften or to show any colour change. They are placed in vats immediately after picking and are covered with 1¼% to 2% lye solution; this solution is allowed to penetrate about two-thirds the distance to the pit (as determined by sampling and applying dilute phenolphthalein solution, a chemical indicator, to the cut surface of an olive). Leaving some bitterness around the pit imparts a more pleasing flavour to the product.

The lye solution is removed and the olives are covered with water, which is changed several times a day for one to two days until the lye is nearly removed. During treatment and washing, undue exposure to the air is avoided, as this causes an undesirable darkening of the fruit.

The olives are next transferred to 180-gallon vats (in Spain) or to 50-gallon oak barrels (in California). These are filled with a salt solution to produce a 7%–8% salt brine. The olives are sealed in these containers for one to six months while lactic acid fermentation takes place. Sugar is often added after several weeks to maintain the fermentation process. Finally, the olives are packed in sealed glass jars filled with a 7½% salt brine.

Canned Ripe Olives.—In California most of the table olive crop is processed as canned black ripe olives. This method is used little or not at all in other olive-producing countries. Harvesting takes place when the fruits are straw-yellow to cherry-red in colour, depending upon the variety. A considerable proportion of the crop is stored in large vats, filled with a 5% to 12% brine, until the olives can be processed. The lactic acid fermentation that takes place in this brine storage prevents the development of spoilage bacteria.

When taken from brine storage, the olives are processed in shallow vats. They are first treated four to eight times with solutions of 1.2% to 2% lye. During this time the olives become darkened by oxidative reactions resulting from exposure to air between the lye treatments or from aeration due to compressed air being bubbled through the water containing the olives.

After the last lye treatment the olives are washed with water repeatedly, from five to seven days, to remove all traces of lye or bitterness. Finally, the olives are pasteurized by heating them in water to 175° F. (about 79° C.) for 30 minutes. This stops any undesirable fermentation.

The olives are then cured in a 2% brine for two days, sorted and graded to size and finally sealed in enamel-lined cans. In California canned olives are sterilized at 240° F. (about 116° C.) for 60 minutes under State Board of Health inspection.

A variation of the above procedure is used in preparing "green-ripe" canned olives. The olives are picked while still green and are processed as soon as harvested. Two lye applications (1.5% to 2%) are given, after which the lye is removed by soaking the olives for several days in water changed three or four times daily. The olives are then stored in a 2% brine for two to three days, then canned as described for the black-ripe process. In the green-ripe method the olives are not exposed to the air at any time during processing, hence they retain their green colour.

PESTS AND DISEASES

Pests.—The olive is not subject to many insect or disease pests. The most important, by far, is the olive fly (*Dacus oleae*), which occurs only in the Mediterranean countries, not being found in the olive-producing regions of the western hemisphere nor in Australia. So serious is this pest that in Spain, Italy and Greece it reduces the olive crop by half in some years. There are three to five generations during the growing season, the first starting in late spring. The larva burrows in the flesh of the fruit, forming cavities, making the fruit unfit for pickling and reducing the yield and quality of the oil. Trees grown under irrigation seem to be more susceptible to attack than those dry-farmed. No completely satisfactory control measures have been developed. Other less troublesome insect pests are black scale (*Saissetia oleae*), olive scale (*Parlatoria oleae*) and the olive kernel borer (*Prays oleae*).

Diseases.—Two diseases attack olives. One is a bacterial disease, called olive knot in California, that is caused by the organism *Bacterium savastanoi*. It causes gall-like growths to develop on the branches and twigs. There is no satisfactory control for this pest other than pruning out and destroying diseased areas as soon as they appear. The second important disease is sometimes termed peacock spot, because of the variegated spots appearing on the leaves in late winter and early spring. This is caused by the fungus *Cycloconium oleaginum*, which infects leaves during the rainy months of the year, causing them to turn yellow and drop in late spring. Sprays of lime sulfur or Bordeaux mixture applied just before the rainy season starts will generally give control.

(H. T. Hn.; X.)

OLIVEIRA MARTINS, JOAQUIM PEDRO DE (1845–1894), Portuguese writer, biographer and one of the first Portuguese exponents of socialism. He was born in Lisbon on April 30, 1845. Lack of money made him interrupt his studies and go into a commercial firm. In 1870 he was appointed manager of the St. Eufémia mine in Spain. He returned to Portugal in 1874 and became administrator of the railway from Oporto to Póvoa. In 1884 he was appointed director of the industrial museum in

Oporto. He joined the Progressive party and in 1886 was elected deputy by Viana do Castelo, soon building up a parliamentary reputation. He had a short and ill-starred term of office as minister of finance in 1892 and died at Lisbon on Aug. 24, 1894.

During his early days in Lisbon Martins had been in contact with the most eminent Portuguese intellectuals and, influenced by the literary group of *O Cenáculo* in which Antero Tarquinia de Quental was prominent, he contributed to *O Pensamento*, a socialist paper. His years in Spain and his direct knowledge of the working class broadened his socialist views and gave him the material for two remarkable books—*Teoria do Socialismo* (1873) and *Portugal e o Socialismo* (1873). After his return to Portugal he published a short series of monographs intended to start a campaign of socialist indoctrination. Turning his attention to Portuguese economic history, he wrote a technical study, *A Reorganização do Banco de Portugal* (1877), to analyze the causes and consequences of the Portuguese financial crisis of 1876. At the same time he sent to the Academy of Sciences in Lisbon a careful analysis of the economic crises of 1846 and 1876—*Memória sobre a circulação fiduciária* (1878). In *As Eleições* (1878) he criticized the existing electoral system and demanded a more democratic representation.

Martins had been interested in history from early youth (he made his literary debut with a historical novel *Phebus Moniz*, 1867) and now, influenced by Proudhon's view that the "theory of socialism is evolution," he embarked on a new venture with *Biblioteca das Ciências Sociais*, in which he attempted to demonstrate the validity of this thesis throughout the great periods of history. His plan begins with a survey of the economic and social structure of primitive societies—*As Raças humanas e a civilização primitiva* (1881), *Quadro das instituições primitivas* (1883)—and closes with a lively picture of the Roman republic—*História da República Romana* (1885). However, in the course of tracing the development of forms of government, he abandoned Proudhon's rigid concept and adopted the views of the German school of anthropology. He thereby came to believe that as a society grows and develops a spiritual element takes shape under the force of historical circumstances. This element becomes in the end the guiding principle of the social group in the form of the unifying national spirit. Imbued with the idea of Hegelian evolution, Martins interpreted the history of the Hispanic peoples—*História da Civilização Ibérica* (1879)—as the result of a common will sustained by the same ideal, explaining Portuguese independence by mere accidental causes. This theory of the chance incident leaves the door ajar for the role of the "great man," the "hero" of Thomas Carlyle. He expounded these views in his biographies *Os filhos de D. João I* (1891), *A Vida de Nun' Álvares* (1893) and the unfinished *O Príncipe Perfeito* (1896). His psychological insight and human sympathy combined with the clarity of his style made him unsurpassed alike in his biographical portraits and in the grandiose frescoes of a battle or the fall of an empire.

OLIVE OIL is the oil extracted from the fleshy part of the ripened fruit (pericarp) of the olive tree, *Olea europaea* (*see* OLIVE). Oil constitutes from 20% to 30% of the ripe fruit, depending on climatic conditions and care in cultivation. About 99% of the world supply of olive oil is produced in the countries of the Mediterranean basin, though it is also produced in California, South America and Australia.

Olive oils can be grouped according to production method: (1) oils obtained from the first mechanical pressing without further treatment; (2) oils from the second pressing, which is made with hot water; and (3) oils extracted with solvents. First-pressing oils are called virgin and their quality depends on the state of the fruit. Only oils from the very best fruit are fit for consumption without further treatment. Only rarely are they exported without being treated; more often they are used as the basis for export types or for local consumption. The crushing apparatus used in expressing the oil varies from the most primitive Roman presses, consisting of conical stones operated by mule or by hand, to the most modern types of hydraulic presses.

The international grades of olive oil are as follows: (1) virgin (first pressing that meets defined standards); (2) pure, or edible (mixture of refined with virgin oil); (3) refined, or commercial (made from refinement of *lampante*, see below); and (4) sulfide (made from extraction with solvents and repeatedly refined). To obtain the best-quality edible oil it is essential that the oil be removed from contact with the residual and putrescible pulp as soon as possible, for the consequent formation of free fatty acids may cause rancidity. In practice the residual pulp is pressed again with hot water and from this pressing is obtained an oil with higher acid content, which together with inferior virgin oils constitutes the oil called *lampante* because of its primitive use as a fuel for lamps. This is further refined to remove acid, colour and odour. It is sold as refined oil, which is used largely for mixing with first-extraction oils to produce edible varieties. Still another type, of inferior quality, is obtained from extraction with a volatile solvent, usually carbon disulfide. This oil's commercial name is sulfur oil and it is used both for food and for industry.

Edible olive oil should be practically devoid of free fatty acids. The *U.S. Pharmacopeia* requires that the fatty acid content of olive oil not exceed 1.41%; however, most export types do not exceed 1%. It varies in colour from clear yellow to golden yellow. Some varieties obtained from unripe fruit have a greenish tinge. Almost every producing country produces oils of varying characteristics and qualities; these variances depend on the districts in which the olive is grown and the degree of ripeness of the fruit.

The precise characteristics of each oil depend on the glycerides formed by saturated or unsaturated fatty acids (*see* OILS, FATS AND WAXES). In olive oil, fatty acids occur in roughly the following percentages: oleic acid 67%–83%, linoleic acid 7%–12%, palmitic acid 5%–15%, stearic acid 1%–4%, myristic acid 1% and others 1%.

Olive oil is sometimes mixed with other vegetable oils. Mixing, however, is not permitted in all countries; in some it is treated as fraud. Adulteration can be detected by chemical analysis.

Pure olive oil is used largely for culinary purposes and in the preservation of foods, particularly canned fish. It is also used in the textile industry (wool combing), in the manufacture of toilet preparations and cosmetics, in the pharmaceutical industry for medicinal purposes, in the manufacture of high-quality castile soap and as a lubricant.

Leading countries in the production of olive oil in the mid-1960s were Spain with an annual production of 387,000 tons, Italy 262,500 tons and Tunisia 115,000 tons. Other principal producing countries were Greece (90,000 tons), Portugal (85,000), Turkey (55,000), the middle east, Algeria and Morocco. All but 5% of the oil produced in the Mediterranean basin was consumed there. World production (excluding the U.S.S.R.), according to the UN Food and Agriculture organization, averaged well above 1,000,000 tons annually.

OLIVER (OLIVIER), **ISAAC** (d. 1617), English miniature painter, whose work is in the first rank of British miniatures, was born at Rouen, France, of French Huguenot parents who took him to London about 1568. He studied under Nicholas Hilliard, and was in Venice in 1596. Apparently he married Sarah, daughter of Marcus Gheeraerts the Elder, the portrait painter, in 1602. Besides miniature portraits he painted small religious and classical pictures. His patrons included Queen Elizabeth I, Henry, prince of Wales, Sir Philip Sidney and Anne of Denmark. His earlier miniatures carry on the fine tradition of Hilliard; his later ones are influenced by the oil painters of that time.

Oliver died, between 50 and 60 years of age, in London, and was buried at St. Anne's, Blackfriars.

His son PETER OLIVER (c. 1594–1647) was his pupil and carried on his later style. Peter copied Italian pictures in miniature, and his signed and dated portraits range from 1619 to 1646. He is said to have painted landscapes in miniature. (C. H. C. B.)

OLIVES, MOUNT OF (also called OLIVET; Arabic JABAL AT TUR), a mile-long ridge of rounded limestone hills facing the Temple mount at Jerusalem and separated from it by the valley of the Kidron. The ridge (in Jordan) has several low peaks, and its northern end joins Mt. Scopus. The northern elevation is highest, about 2,723 ft. above sea level. The second (about 2,641 ft.), called the Ascension, is the traditional site of Jesus' ascension. There the emperor Constantine built a rotunda and a basilica, and a number of other sanctuaries were constructed later. This peak stands directly opposite to the east gate of Jerusalem, being 371 ft. above the bed of the Kidron and 208 ft. higher than the Temple plateau. The third summit is called the Prophets and the fourth the Mount of Offense, where Solomon built the idolatrous shrines for his heathen wives. The Mount of Olives is referred to only four times in the Old Testament: David fled over it barefoot from Absalom (II Sam. xv, 30); there was a shrine on its summit (II Sam. xv, 32); the glory of the Lord appeared there to Ezekiel (Ezek. xi, 23); and Zechariah pictured God standing there to go forth against Jerusalem's enemies (Zech. xiv, 4). Jesus often went to the Mount of Olives, and it is mentioned frequently in the New Testament. He was welcomed by the multitude as he descended its slope; from there he prophesied the destruction of the Temple; after the Last Supper he returned there to wait and pray; his ascension took place somewhere on its slopes. Bethphage was somewhere on the mount; Bethany was over its southern shoulder, and Gethsemane was at its foot. There are a number of Christian and Muslim enclosures and buildings on the slopes. (E. D. GR.)

OLIVETANS (ORDO S. BENEDICTI MONTIS OLIVETI), a monastic order following the Benedictine rule, founded by St. Bernard Tolomei, a Sienese nobleman. The Olivetans were independent till 1962, when they obtained the status of a Benedictine congregation. *See* BENEDICTINES: *Independent Orders;* ORDERS AND CONGREGATIONS, RELIGIOUS.

OLIVINE, an important rock-forming mineral composed mainly of magnesium and ferrous orthosilicate. The name alludes to those common varieties which have an olive-green colour and is often applied incorrectly to other green stones. The transparent varieties used in jewelry are known as precious olivine, chrysolite (not to be confused with chrysotile, a serpentine) and peridot (*see* also GEM). These are obtained chiefly from St. John's Island, Egy., in the Red sea; upper Burma; and Minas Gerais, Braz. The common variety, which is relatively infusible, withstanding temperatures of more than 1,500° C., is used as a refractory brick in special applications.

Olivine is a common constituent of many basic and ultrabasic igneous rocks such as basalt, gabbro, peridotite and dunite, which is an almost pure olivine rock. It also occurs as an accessory constituent of some metamorphosed rocks, particularly the dolomitic marbles and schists. In stony meteorites (*q.v.*) it is a principal constituent, and is occasionally imbedded in iron meteorites. Iron-rich olivine is often found in slag.

The mineral occurs usually as compact or granular masses or as grains and blebs in the rock of which it is a constituent. Faceted crystals are not common. The colour is variable, with shades of green, yellowish-brown, gray and black. Olivine alters readily to a serpentine, chlorite or an amphibole and anhydrous and hydrous iron oxides such as magnetite, hematite, goethite and lepidocrocite. By weathering processes the mineral is altered to carbonates or hydrous iron oxides and silica.

In addition to the magnesium and iron, common olivine contains small amounts of manganese, calcium and, rarely, zinc and lead. When some of these components are dominant the olivine is called forsterite, Mg_2SiO_4; fayalite, Fe_2SiO_4; tephroite, Mn_2SiO_4; and monticellite, $CaMgSiO_4$. These pure end members of the olivine group have been synthesized in the laboratory. Forsterite and fayalite are known to form a complete series of solid solutions or mix crystals.

The hardness of olivine is 6.5 to 7; the specific gravity, 3.22 to 4.32; and it is brittle, breaking with a conchoidal fracture or along two indistinct and inequal cleavages. The mineral is decomposed by hot hydrochloric acid, forming gelatinous silica. Under the microscope it is distinguished by its high index of refraction (1.64–1.88) and its double refraction (birefringence = 0.033–0.051).

All members of the olivine group crystallize in the orthorhombic system and have the same crystal structure as deduced by X-ray diffraction. The general formula is $XYSiO_4$, where X and Y may be magnesium, ferrous iron, manganese, calcium, zinc and lead. Fayalite inverts to a spinel (*q.v.*) structure (cubic) under extreme pressures.

OLLIVIER, OLIVIER ÉMILE (1825–1913), French statesman and writer, chief minister in Napoleon III's "liberal empire" of 1870, was born at Marseilles on July 2, 1825, the son of the revolutionary Demosthène Ollivier. He studied law in Paris and was admitted to the bar in 1846. An adherent of the socialist and romantic movement, he was appointed commissary-general of the Bouches-du-Rhône *département* at the outbreak of the revolution of 1848; but his idealistic policy there alienated both radicals and conservatives, and in July he was demoted to the prefecture of Haute-Marne. When Louis Napoleon became president of the republic, Ollivier was dismissed from office (Jan. 1849). Compelled to abandon his socialist activities by the despotism of the Second Empire, he concentrated on his legal practice and rose to the first rank as a barrister.

Elected to parliament in 1857, Ollivier became one of the republican minority known as "the Five." He made vigorous attacks on Napoleon III's dictatorship but differed from most of his republican allies in believing that forms of government mattered little, that revolutions often produced evils worse than those which they remedied and that the opposition should therefore seek not to overthrow the empire by force but to persuade it to grant liberty to the country. So, when the emperor made the liberal concessions of Nov. 24, 1860, Ollivier welcomed them and offered his support to the empire if Napoleon would establish representative government. He soon broke with the republicans and, together with the duc de Morny, worked for a "liberal empire," a compromise between Napoleonic autocracy and parliamentary government. His ideas fitted well with Napoleon's, and on Jan. 2, 1870, he was appointed minister of justice at the head of a liberal government chosen from the leaders of the majority in parliament. He drew up a new constitution (approved in a plebiscite by nearly 70% of the votes) and set up numerous commissions to prepare the complete reform of such questions as the relationship of labour and capital, education and law. He seemed to have transformed the empire from despotism to constitutional monarchy without bloodshed or violence.

Ollivier's work was ruined by the outbreak of the Franco-German War (*q.v.*). He had no wish for war, but allowed the control of events to slip out of his hands, so that when Bismarck's "Ems telegram" was published he considered it an intolerable insult to France and declared war (July 19, 1870). The French military reverses soon obliged him to resign, which he did on Aug. 9. He withdrew to Italy.

Returning to France in 1873, Ollivier lived mainly at St. Tropez and took no further part in politics. His former republican colleagues, now ministers of the third republic, decried him as a traitor for having gone over to Napoleon III and for having undertaken "with a light heart" a war that had brought national disaster. Yet he might have achieved much had his experiment of the liberal empire not been cut short. Moreover, he had wide interests and varied talents: his writings include a study of Michelangelo, a novel and volumes on ecclesiastical affairs as well as political books. His great work, however, is *L'Empire libéral,* partly a history of the second empire and partly his memoirs: 16 volumes of it appeared between 1895 and 1912, the last volume and the index posthumously (1915, 1918). His first marriage (1857) was to Blandine Liszt, Franz Liszt's daughter by Mme d'Agoult. A member of the Académie Française from 1870, Ol-

livier died at St. Gervais-les-Bains (Haute-Savoie) on Aug. 20, 1913.

OLMEDO, JOSÉ JOAQUÍN (1780–1847), Ecuadorian poet and statesman, whose patriotic verse reflects the revolutionary spirit of his time, was born in Guayaquil on March 20, 1780. He studied at the University of San Marcos in Lima, receiving his LL.D. degree in 1805. He was sent to Spain in 1811 to represent Guayaquil in the *Cortes de Cádiz*. After his return in 1816, he participated actively in politics and continued writing poetry. In 1825 he again went to Europe, this time to represent Peru in London and Paris. He returned to Guayaquil in 1828 and when Ecuador became a republic in 1830 he was elected its first vice-president but declined the honour. He died in Guayaquil on Feb. 19, 1847.

As a poet, Olmedo is a neoclassicist. He is best known for his odes *La victoria de Junín: Canto a Bolívar* (1825), the finest example of heroic poetry in the neoclassical style written in Spanish America, and *Al General Flores, vencedor en Miñarica* (1835), an eloquent composition lamenting the civil wars that were beginning to destroy the unity of South America, so soon after independence from Spain had been achieved.

For his collected poems *see* A. Espinosa-Pólit, *Poesías completas de José Joaquín de Olmedo*, with bibliography (1945; 1947).

See E. C. Hills, ed., *The Odes of Bello, Olmedo and Heredia* (1920). (L. Ll.)

OLMSTED, FREDERICK LAW (1822–1903), U.S. landscape architect, was born in Hartford, Conn., on April 27, 1822. He already had an adventurous career when he published his *Journeys and Explorations in the Cotton Kingdom* (1861), which gave a picture of the conditions surrounding American slavery that had great influence on British opinion, and was much quoted in the controversies at the time of the Civil War. During the war he was the untiring secretary of the U.S. sanitary commission.

When Central park, New York city, was projected, he, in conjunction with Vaux, proposed the plan which, in competition with more than 30 others, won first prize. Olmsted was made superintendent to carry out the plan. This was practically the first attempt in the United States to apply art to the improvement or embellishment of nature in a public park; it attracted great attention, and the work was so satisfactorily done that he was engaged thereafter in most of the important works of a similar nature in America—Prospect park, Brooklyn; Fairmount park, Philadelphia; South park, Chicago; Riverside and Morningside parks, New York; Mount Royal park, Montreal; the grounds surrounding the Capitol at Washington, and at Leland Stanford university at Palo Alto, Calif.; and many others.

He developed the bare stretch of lake front at Chicago into the world's fairgrounds, contributing much to the architectural beauty and the success of the exposition. He was greatly interested in the Niagara reservation, made the plans for the park there, and also did much to influence the state of New York to provide the Niagara park.

He was the first commissioner of the national park of the Yosemite and the Mariposa grove, directing the survey and taking charge of the property for the state of California. He also held directing appointments under the cities of New York, Boston, Philadelphia, Baltimore, Wilmington and San Francisco, the joint committee on buildings and grounds of congress, the Niagara Falls Reservation commission, the trustees of Harvard, Yale, Amherst and other colleges and public institutions. After 1886 he was largely occupied in laying out an extensive system of parks and parkways for the city of Boston and the town of Brookline, and on a scheme of landscape improvement of Boston harbour.

Olmsted died on Aug. 28, 1903.

OLMÜTZ: *see* Olomouc.

OLNEY, RICHARD (1835–1917), U.S. lawyer and secretary of state, was born at Oxford, Mass., on Sept. 15, 1835. After graduation from Brown university in 1856 and from Harvard law school two years later, he began the practice of law in Boston. A Democrat in politics, he served one term in the state legislature but failed of reelection and was not widely known in 1893 when Pres. Grover Cleveland appointed him a member of his cabinet as attorney general. In this position, during the strike of railway employees against the Pullman company in Chicago in 1894, he instructed the U.S. attorneys to obtain injunctions from the federal courts to restrain the strikers from acts of violence, and thus set a precedent for what came to be called "government by injunction." He also advised the president to use federal troops to quell the disturbances in the city, on the ground that the federal government must prevent interference with the mail and with interstate commerce.

In June 1895, Olney became secretary of state, succeeding Walter Q. Gresham, who died in office. Olney became involved almost immediately in a controversy with Great Britain concerning a boundary dispute over British Guiana between the British and Venezuelan governments. On July 20, 1895, in a note to the British government he announced the so-called "Olney corollary" to the Monroe Doctrine—that intervention by the United States was permissible and even desirable to force a settlement of any dispute involving the Monroe Doctrine. The secretary went so far as to declare that, "Today the United States is practically sovereign on this continent, and its fiat is law upon the subjects to which it confines its interposition." Fortunately the British did not want war, and eventually arbitrated the boundary line in 1899. Olney also was the author of an arbitration treaty with Great Britain, the Olney-Pauncefote treaty, which failed to win approval by the senate in May 1897. At the expiration of Cleveland's term in March 1897, Olney returned to the practice of law and refused all offers to return to public life. He died in Boston on April 8, 1917.

See S. F. Bemis (ed.), *The American Secretaries of State and Their Diplomacy*, vol. 8 (1928); Henry James, *Richard Olney and His Public Service* (1923).

OLNEY, a market town in the Newport Pagnell rural district of Buckinghamshire, Eng., on the Ouse 20 mi. N.E. of Buckingham by road. Pop. (1961) 2,384. William Cowper the poet lived there from 1767 to 1786. John Newton, curate of Olney, had Cowper's assistance in the production of the *Olney Hymns*. The town has agricultural associations, a tannery and a craftsman-made furniture industry. Olney has revived the ancient custom of a pancake race run on Shrove Tuesday at 12 noon, in which women competitors toss their pancakes three times while racing from the market place to the parish church, where a service follows. It is run in competition with Liberal, Kansas, where a similar race takes place. (R. W. Du.)

OLOMOUC (Ger. Olmütz), a town in the North Moravian *kraj* (region) of Czechoslovakia, 72 km. (45 mi.) N.E. of Brno by road. Pop. (1961) 72,348. It is one of the oldest towns of Moravia, lying close to an isolated craggy hill detached from the foothill country of northwestern Moravia, and on the west bank of the Morava at its confluence with the Bystrice. Southward stretches the Hana region comprising some of the most fertile land in Moravia, with rich soils formed on loess deposits.

Historical buildings in the city include the fine 14th-century Gothic cathedral, with a tower 328 ft. high and the 15th-century town hall, with an impressive tower adorned by Anton Pohl's astronomical clock. The great square, characteristic of many towns in Czechoslovakia, contains an 18th-century Trinity column.

Road and rail routes converge on Olomouc. Its industries are based on the specialized farming of the south: sugar refineries, malthouses, a brewery, cheese and edible fat factories. It has the largest refrigeration plant in Moravia and engineering and building industries are also prosperous.

Olomouc is thought to have its origin in a Roman fort (Mons Julii), and its name is possibly a garbled form of this classical term. The bishopric dates from 1063 and was raised to an archbishopric in 1777. At the peace of Olomouc (1478), Moravia was ceded to the king of Hungary. Olomouc was reckoned as the capital of Moravia until the Thirty Years' War. Its long occupation by the Swedes damaged its usefulness as a regional capital and from 1640 Brno was recognized as the first city in Moravia. Until

1886 the main importance of Olomouc was that of a strongpoint and its military significance was greatest in the mid-18th century during the struggle between Frederick the Great of Prussia and Maria Theresa of Austria over Silesia. The Emperor Ferdinand I of Austria abdicated there in 1848 in favour of the young Francis Joseph and the Olmütz convention of 1850 restored the German confederation. In the late 19th century the fortifications were demolished and its manufacturing and trading functions began to develop, stimulated by railway building. The university (founded 1576) was suppressed in 1858, and there survived only the theological seminary with a famous library; it was revived after World War II and named after the patriot-historian F. Palacky. In the middle ages and early modern history Olomouc was mainly a community of German merchants. As late as 1900, of a population of 21,000 two-thirds were reckoned as German. (H. G. S.)

OLONA (*Touchardia latifolia*), a shrub of the nettle family (Urticaceae), native to the Hawaiian Islands, where it has long been cultivated as a fibre plant. The bast fibre obtained from the young shoots possesses remarkable tensile strength, being three times as strong as that of the finest grades of abacá fibre (*q.v.*). Because of its great pliability, olona fibre is readily woven into cloth or made into cordage. Another valuable quality is its unusual durability in water, making it especially suitable for fish nets.

OLSZTYN (Ger. ALLENSTEIN) a town of northeastern Poland, headquarters of the *wojewodztwo* (province) of the same name, is situated on the Lyna river and three lakes, about 195 km. (121 mi.) N. of Warsaw by road. Pop. (1960) 68,000. Old buildings include a Gothic castle, a Gothic cathedral (14th–16th century) and parts of the walls. There is the Masurian Regional museum and a school of agriculture. The town is an important rail and road centre. It is the seat of the Warmia (Ermland) bishopric. The Teutonic knights founded a castle there in 1334 and the surrounding settlement acquired town rights in 1353. In 1466 the town with the historic region of Warmia became Polish and was annexed by Prussia (1772). Extensively damaged during World War II, it was returned to Poland in 1945 and was entirely resettled by Poles.

OLSZTYN *wojewodztwo* extends to the Russian frontier in the north. Pop. (1960) 876,700; area 8,117 sq.mi. The population density, 108 per square mile, is one of the lowest in Poland. The forests (23% of the total area) and the Masurian lakeland (including Sniardwy, the largest lake in Poland) make the province an important tourist region. There is little industry but timber and food production are important. Apart from Olsztyn the chief towns are Ostroda (17,700), Ketrzyn (16,100), Gizycko (14,900), Szczytno (12,900), Lidzbark Warminski (11,100), Ilawa (11,900), Bartoszyce (11,700) and Mragowo (10,800). (T. K. W.)

OLYBRIUS (d. 472), western Roman emperor from April to November 472, was not recognized in the east. Before his elevation he was a wealthy senator, married to Placidia, the daughter of Valentinian III. Gaiseric, king of the Vandals, hoped that Olybrius could be made western emperor, and this support made him suspect to the eastern emperor Leo I. Leo sent him from Constantinople, where he was then living, to Rome, hoping that he would be killed there. But in fact Ricimer elevated him to the throne soon after his arrival. The reigning emperor, Anthemius, was overthrown and put to death on July 11, 472; but Ricimer himself died soon afterward. Olybrius, however, survived him by only two months, dying on Nov. 2. Nothing is known of his character. (E. A. T.)

OLYMPIA, a place in Greece in the western Peloponnese, scene of the Olympic games (*see* also GAMES, CLASSICAL). Olympia lies on the northern bank of the Alpheus (Alfios) river about 10 mi. from its mouth. A tributary stream, the Cladeus (Kladios), joins the Alpheus just below Olympia, to the south. The country is rich and well watered, consisting of low wooded hills alternating with farmland.

HISTORY

Traces of Early Bronze Age habitation have been found in the environs of Olympia, but the earliest remains on the site of the classical sanctuary are some apsidal houses of the Middle Bronze Age (2000–1600 B.C.). These were abandoned, covered by a deep layer of silt and quite forgotten. There are no remains of the Late Bronze (Mycenaean) Age at Olympia itself, although again some have been found in the environs.

The origins of the classical sanctuary go back to the beginning of the Iron Age around or soon after 1000 B.C. Bronze statuettes and other votives dating from this period have been found. The sanctuary at this time was under the control of the neighbouring town of Pisa, but Elis also had some share in it. Elis soon allied itself with Sparta and increased its share of the control. Some time about 570 B.C. the allies defeated Pisa and from then on the Eleans were the religious supervisors of Olympia while the Spartans constituted themselves its political protectors. There were various traditions as to the origin of the games. According to one the first race was between Pelops and Oenomaus (*qq.v.*), who used to challenge the suitors of his daughter Hippodameia and then slay them when they lost. Another attributed the festival to Heracles. The list of Olympic victors begins in 776 B.C. with Coroebus of Elis, and this list is often cited by ancient authors for purposes of dating, the name of the winner of the footrace usually being given. In later antiquity the Olympiads were numbered for greater convenience of reference.

The festival occurred every four years and was held in high summer at the time of the full moon, that is, roughly our month of August. A sacred truce was declared so that even in time of war any who wished might have safe conduct to the games. Athletes who participated had trained for ten months before the games, the last month at the gymnasium in the town of Elis about 25 mi. N.W. of Olympia. The festival lasted for five days, and in the 5th century B.C. the events were distributed as follows: On the first day the final scrutiny of the athletes took place to determine their eligibility, and oaths were taken in the Bouleuterion or council house. On the second day came the chariot and horse races and the pentathlon. The third day, the day of the full moon, was reserved for the great sacrifice to Zeus; in the afternoon the events for boys took place. On the fourth day came the chief athletic events, footraces in the morning and wrestling, boxing and *pankration* (a combination of wrestling and boxing) in the afternoon. The last day was given over to feasting and celebration. The victor's prize was a crown of wild olive made from the tree called "the olive of the fair crown" which grew behind the temple of Zeus. The victor received a hero's welcome on his return home, and odes were often composed in his honour; 14 of Pindar's odes celebrate Olympic victors.

The sanctuary was seriously damaged in A.D. 267 as a result of the invasion of the Heruli. A fortification wall was built soon after, using fragments of ruined buildings, which enclosed the heart of the sanctuary, the temple of Zeus and the Bouleuterion. The games continued, however, for more than a century until they were abolished by the emperor Theodosius I probably in A.D. 393, the 293rd Olympiad. The last recorded Olympic victor is the Armenian prince Varazdates, who won the boxing match in A.D. 385.

Excavations.—The first excavations were conducted on the site of the temple of Zeus in 1829 by the French Expédition Scientifique de Morée (A. Blouet). The temple was sufficiently cleared to reveal its general plan, and fragments of three sculptured metopes were found; these are now in the Louvre museum, Paris. The great German excavations of 1875–81 cleared the whole of the sacred precinct and some buildings that lay outside it and fixed by exploratory trenches the position of the stadium. Thus the plan of a great Greek sanctuary was revealed for the first time. In the early years of the 20th century some small-scale exploratory digging was done in the deeper layers in the sanctuary. Large-scale work was resumed by the Germans in 1936, one of the chief aims being the excavation and restoration of the stadium. Interrupted by World War II in 1942, it was resumed in 1952. In 1960 the excavation of the stadium was completed, and its restoration in 1961. Other structures were explored in this period, the most important of which was the workshop of Phidias.

THE REMAINS

The sacred precinct was called the Altis or "sacred grove of

Zeus." It was an irregular quadrangular area over 200 yd. on a side, bounded on the north by the hill of Cronus and enclosed by a wall on the other three sides. In it were the temples of Zeus and Hera, the principal altars and votive offerings, the treasuries and administration buildings. Outside were the athletic installations and the hostels, baths and other accommodation for visitors.

Temple of Zeus.—This was the largest and most important building at Olympia and one of the largest Doric temples in Greece. It was built about 460 B.C. by the architect Libon of Elis. The material was a coarse local shell-conglomerate, the exposed surfaces of which were covered with a coat of fine white stucco. The temple had 6 columns across the front and 13 on the sides. There was a pronaos and an opisthodomos, and the cella was divided into three aisles by two rows of slender columns arranged in two stories. (*See* also GREEK ARCHITECTURE.) The roof tiles were of marble.

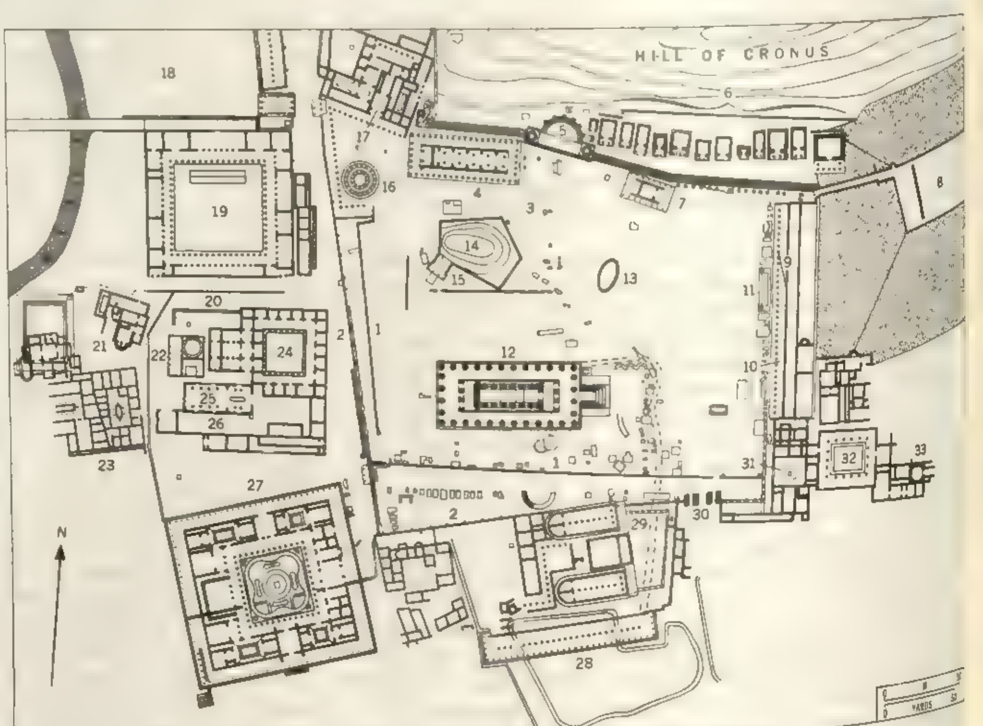
The temple was richly decorated with sculpture, much of which has survived and is to be seen in the Olympia museum. In the front gable the chariot race between Pelops and Oenomaus was represented and both parties were shown preparing for the race. In the back gable was the battle of the Lapiths and Centaurs at the wedding of Perithous. These sculptures are masterpieces of the early classical style, but the name of the artist is not known. Pausanias' attribution of them to Paeonius and Alcamenes is generally rejected as these sculptors are known to have worked in the later 5th century. The frieze that ran above the front and back porches had sculptured metopes with the 12 labours of Heracles, six at each end. At the peak of the gable was a gilded figure of Victory and at each corner a gilded caldron, but these have not survived.

Within the temple was the great gold and ivory statue of Zeus, the work of the Athenian sculptor Phidias (*q.v.*). This was the most famous of all ancient statues and was counted one of the seven wonders of the world. It made a profound impression on all who saw it, and people were generally agreed that Phidias had succeeded in creating the image of Homer's Zeus. The god was represented seated on an elaborately wrought throne. He held a Victory in his right hand and a sceptre in his left. (*See* also GREEK ART: *The Classical Period* [*c. 480–c. 330 B.C.*].)

Workshop of Phidias.—This statue was made piece by piece by Phidias and his collaborators in a building just outside the Altis to the west of the temple. This building, subsequently converted into a church, was still known in the time of Pausanias as the "workshop of Phidias." The excavations of 1954–58 brought dramatic confirmation of the identification. In the deeper layers in and around the building, particularly toward the south, a great mass of material that was evidently waste from an artist's atelier was found. This material was of various kinds: tools, slivers and worked fragments of ivory and bone, glass ornaments and molds. The molds are of clay of a very heavy fabric, like roof tiles, and the larger ones are sometimes reinforced with iron rods. They are of an unusual open form and were evidently used for hammering into shape the thin plates of gold that formed the statue's drapery. The pottery found with this debris indicates that the workshop was active in the years around 430 B.C., an important fact because it settles an old controversy as to whether Phidias made the Zeus before or after his other great chryselephantine statue, the Athena Parthenos, which was completed in 438 B.C. The new evidence is decisive in favour of the later date. One of the pieces of pottery, a ribbed mug, has inscribed on its bottom in neat clear letters the words "I am (the property) of Phidias."

Altar of Zeus.—The great altar of Olympian Zeus was not in front of the temple, as might have been expected, but to one side, and nearer the temple of Hera. It was elliptical in shape and consisted of an elevated base approached by steps. From the base rose a large mound made of the ashes of the thighs of victims sacrificed to Zeus. The whole height of the altar was 22 ft.

Temple of Hera.—This was the oldest temple at Olympia and one of the most venerable in all Greece. It was originally a joint temple of Hera and Zeus until a separate temple was built for the latter. It has sometimes been thought that the temple of Hera was built in the 10th or 11th century B.C., but this view is now rejected. The existing temple was probably built about 600 B.C., and an earlier phase, without peristyle, may go back to the 8th century. The temple is long and narrow, having 6 columns across the ends and 16 along the sides. The columns are Doric and show a great variety of styles. This is because they were originally of wood and were gradually replaced in stone. In the 2nd century A.D. there was still one wooden column in the back porch. The entablature was of wood and the upper parts of the walls were of mud brick. The cella had two interior rows of columns, alternate columns being attached by spurs to the cella walls and thus forming bays. Pausanias says that in the temple was an image of Hera seated on a throne with an image of Zeus standing beside her. An archaic limestone head thought to be that of the Hera has been found. Pausanias also reports a stone statue of Hermes carrying the young Dionysus, a work of Praxiteles; this statue was found in the cella of the temple in 1877 and is one of the most prized possessions of the Olympia museum.



FROM M. SANTANGELO "IL SANCTUARIO DEI GIUOCHI OLIMPICI," ROME, 1960

PLAN OF THE SANCTUARY AT OLYMPIA

(1) Greek walls of the Altis; (2) Roman walls of the Altis; (3) Helladic settlement; (4) Temple of Hera; (5) Exedra of Herodes Atticus; (6) Terrace of the treasuries; (7) Metroum; (8) Stadium; (9) early classical starting line; (10) Echo Colonnade; (11) Bases of columns supporting the statues of Arsinoe and Ptolemy II; (12) Temple of Zeus; (13) Altar of Zeus (?); (14) Sanctuary of Pelops; (15) Terrace retaining wall; (16) Philippeum; (17) Prytaneum; (18) Gymnasium; (19) Palaestra; (20) Theokoleon; (21) Greek bath; (22) Baths; (23) Hospitium; (24) Roman house; (25) Byzantine church; (26) Workshop of Phidias; (27) Leonidaeum; (28) Southern stoa; (29) Bouleuterion; (30) Neronian entrance; (31) Hellanodikeion; (32) House of Nero; (33) House of the Octagon

Treasuries.—A row of 12 treasuries overlooks the Altis from the lowest slopes of the hill of Cronus. These are small structures in the form of a Doric temple *in antis* and date from the 6th century B.C. All were erected by Dorian states ranging from Byzantium to Gela in Sicily and Cyrene in North Africa. In the case of only three, Sicyon, Megara and Gela, is enough material available to allow a reconstruction on paper. These treasuries were erected by the several states either as thank offerings for Olympic victories gained by its citizens or as a general mark of homage to Olympian Zeus and to contain the dedicated gifts in which the wealth of the sanctuary consisted.

Sanctuary of Pelops and the Metroum.—The Elean hero Pelops had a sanctuary in the Altis between the temples of Zeus and Hera. It was an open-air sanctuary surrounded by a wall, and trees grew in it and statues were set up.

The Metroum or temple of the Great Mother of the Gods was a small Doric temple of the 4th century B.C. just below the treasuries. The cult no longer existed in Roman times, and the temple contained statues of Roman emperors.

Philippeum, Prytaneum and Exedra of Herodes.—A round building of the Ionic order, with Corinthian half columns on the inside, was erected by Philip of Macedonia to commemorate his victory over the Greeks at Chaeronea in 338 B.C. It contained gold and ivory statues of Philip, Alexander and other members of their family.

The Prytaneum was a building in the northwest corner of the Altis which contained a hearth on which burned a perpetual fire, and a banquet room in which the Olympic victors were feasted. A large, lavishly decorated fountain, on an apsidal plan, was erected by Herodes Atticus in the name of his wife Regilla. On it were displayed some 20 statues of Herodes and his family and of members of the imperial family including Hadrian and Antoninus Pius.

Echo Colonnade.—This building was officially called the Stoa Poikile or "painted colonnade" from the paintings that used to be on its walls. The popular name was given it because the echo repeated a word seven times or more. The colonnade closed the east side of the Altis and was separated from the east Altis wall which supported the stadium embankment by a narrow passage. The colonnade was built soon after the middle of the 4th century B.C. Deep down beneath its floor the starting line of the early classical stadium has been found.

Zanes.—These were bronze statues of Zeus erected with money from fines imposed on those who wantonly violated the rules of the games. The bases of 16 of these have been found just outside the covered entrance to the stadium, the entrance by which the athletes entered.

Bouleuterion.—The Bouleuterion or council house lies just outside the Altis to the south. It comprised two Doric buildings of different date but identical oblong form with apsidal ends toward the west. In the space between was a rectangular court at the centre of which stood the statue of Zeus Horkios ("Zeus who presides over oaths"). Beside this statue the athletes took the oath not to indulge in foul play during the contests.

Outside the Altis to the southwest stood the Leonidaeum, a large hostel for the reception of distinguished visitors, built in the 4th century B.C. and remodeled in Roman times. To the northwest were the Palaestra, where wrestlers and boxers trained, and the gymnasium with an elaborate entrance gateway and a covered running track.

Stadium.—The stadium lay to the east of the Altis. In early classical times it was not cut off from the sanctuary, and one end of the track was in the area directly in front of the temple and the great ash altar of Zeus (beneath the later Echo Colonnade). About the middle of the 4th century B.C. the stadium was shifted about 90 yd. eastward and a little to the north. The track was surrounded by massive sloping embankments of earth for the accommodation of the spectators, except to the north where the natural slope of the hill sufficed. The western embankment, parallel to which the Echo Colonnade was built, effectively cut the stadium off from the Altis. Connection between the two was maintained by what was called the Krypte or "covered entrance" which pierced the embankment and, in Roman times, was covered with a stone vault. This entrance was used by the athletes and the umpires. There were no stone seats in the stadium except for a box on the south side about one-third of the way from the starting line nearest the Altis; here the *Hellanodikai* or chief judges of the games sat. Directly opposite this was the altar of Demeter Chamyne from which the priestess of that cult was privileged to watch the games (married women were excluded from the Olympic festival but unmarried girls were permitted). The track was about 230 yd. long and 35 yd. wide. It was separated from the sloping embankments by a low stone parapet beside which ran an open stone water channel with basins at intervals. The actual course was marked by stone starting lines at either end. These were about 210 yd. apart (192.27 m. = 600 Olympic feet). There was space for 20 runners at a time. The classic race was the *stade, i.e.*, one length of the course. There was also a *diaulos*, two lengths, and a *dolichos* or long-distance race, the length of which varied and might be as much as 24 stades or nearly three miles. Other athletic contests were also held in the stadium. This 4th-century stadium has been fully excavated and its track and embankments restored so that it may be seen as it was in late classical times.

When the stadium embankments were excavated many votive offerings were discovered. Some of these were works of art of various kinds, including bronze statuettes and reliefs and several terra-cotta statues of which the most noteworthy was a group of Zeus and Ganymede, about half life size and dating from around 470 B.C. Others were arms or armour that had been dedicated in the sanctuary, and the Olympia museum houses the largest collection of ancient Greek weapons in the world. Some of these pieces have identifying inscriptions on them and so are interesting historical documents. Mention may be made of a helmet of Corinthian type with the name of Miltiades, the victor of Marathon, and a Persian helmet with the inscription "The Athenians (dedicated the helmet) to Zeus, having taken it from the Medes."

The hippodrome where the horse races were held lay south of the stadium in the open valley of the Alpheus. No trace of this has been found. Pausanias gives a long description of the hippodrome and of the elaborate starting machinery.

OLYMPIA, the capital city of Washington, U.S., and the seat of Thurston county, at the extreme southern end of Puget sound, is located 60 mi. S.S.W. of Seattle. The city is surrounded on the landward sides by low green hills. On the south the Deschutes river flows through a rocky canyon into Deschutes basin, a fresh-water lake that is part of the capitol grounds, with an outlet to Puget sound. To the north are the snow-capped Olympics, and to the east rises Mt. Rainier in the Cascades. On a promontory jutting into the sound stand the white sandstone state government buildings, of classic design.

The trade of the port of Olympia, averaging about 500,000 tons per year, consists of logs, lumber, plywood, forest products of all types, ores, petroleum products, aluminum and steel products, beverages and military supplies and other products from local industries, including processed foods. It is a centre of oyster culture, producing both the large Pacific oysters and the small, Olympia oysters. Olympia is headquarters of the Olympic National Forest service. Three miles south of the city's centre is St. Martin's college (Roman Catholic, 1895) for men.

The first American settlement on Puget sound was made in 1845 at the falls of the Deschutes river, on the site of Tumwater, 1 mi. S. of Olympia, under the leadership of Michael T. Simmons from Kentucky. In 1849 Tumwater was practically deserted when the men left for the California gold fields, but in 1850 a town was laid out on the site of some homesteads where Olympia now stands. At

first called Smithfield, after one of the early settlers, the town was renamed shortly for the Olympic mountains. In 1851 congress authorized the establishment of a customhouse, making Olympia the first port of entry on Puget sound. In 1852 the first newspaper north of the Columbia river in Oregon territory was established there (the *Columbian*). In 1853 Olympia became the capital of the newly created Washington territory, upon the arrival of the first governor, Isaac I. Stevens. It was chartered as a city in 1859. A monument in Capitol park marks the terminus of the Old Oregon trail. For comparative population figures *see* table in WASHINGTON (STATE): *Population.* (R. E. BU.)

OLYMPIAS (*c.* 375–316 B.C.), wife of Philip II of Macedonia and mother of Alexander the Great, was the daughter of Neoptolemus, king of Epirus (her original name was apparently Myrtale; she may have been called Olympias after Philip's victory in the Olympic games of 356). Philip's polygamy did not threaten her position until in 337 he married a high-born Macedonian, Cleopatra. Olympias withdrew to Epirus, returning after Philip's assassination (336), when she killed Cleopatra and her infant daughter. On departing for his invasion of Asia (334), Alexander appointed Antipater (*q.v.*) regent of Macedonia. He and Olympias quarreled repeatedly; Olympias eventually retired *c.* 331 to Epirus, which she virtually ruled after the death of her brother Alexander I in Italy.

After Alexander the Great died (323) Antipater continued to control Macedonia until his death in 319. His successor Polyperchon invited Olympias to return and act as regent for her young grandson Alexander IV, but she did not do so until 317, when Antipater's son Cassander had established Philip II's half-witted son Philip III (Arrhidaeus) as king of Macedonia. The Macedonians went over to Olympias without a battle. She killed Philip and his wife Eurydice, Cassander's brother and a hundred of his partisans. Cassander re-entered Macedonia; Olympias was blockaded in Pydna, surrendering in spring 316. She was condemned to death, but the soldiers sent by Cassander refused to execute her; she was finally killed by relatives of those she had executed.

Ancient writers made much of Olympias' passionate and imperious character, her ruthlessness and her devotion to the orgiastic cult of Dionysus; many of the stories they record are, however, probably pure invention. *See* also MACEDONIA, KINGDOM OF.

OLYMPIC GAMES. While the origin of the Olympic games is not known exactly, traditionally the first celebration of the ancient games was in 776 B.C. Thereafter they were held at four-year intervals until *c.* A.D. 393, when they were abolished by the Roman emperor Theodosius I after Greece had lost its independence. Few enterprises created by man have lasted so long. At first the program was confined to one day and consisted only of a single event, a race the length of the stadium. Afterward additional races, the discus throw, the javelin throw, the broad jump, boxing, wrestling, the pentathlon, chariot racing and other events were added, and the duration, including the religious ceremonies, was extended to seven days. Participation in the games was at first restricted to Greeks, but competitors came from all of the Greek colonies. A sacred truce was declared and enforced to permit participants to travel unmolested to the games. Women were not allowed as competitors or, except for the priestesses of Demeter, as spectators. Before the contests opened all the competitors and their families, the trainers and the judges swore a solemn oath to keep the competition clean and fair and to give just decisions.

The games occupied such an important position in the life of Greece that time was measured by the four-year interval between them—an "Olympiad." The greatest honour then to be attained by any Greek was the winning of the simple branch of wild olive given to a victor in the games. Kings competed alongside commoners; even the Roman emperor Nero (A.D. 37–68) sought Olympic honours. Winners became national heroes, musicians sang their praise and sculptors preserved their strength and beauty in marble. Their feats of skill and courage were recorded by the poets and writers of the time. The gracefulness and sportsmanship of the contestant and the method of winning were esteemed equally with the victory itself. (*See* also GAMES, CLASSICAL: *Greece.*)

It was through the efforts of Baron Pierre de Coubertin (1863–1937) of France, a brilliant educator and scholar but not an athlete, that the Olympic games were revived. Having decided that at least one of the reasons for the glory of the Golden Age of Greece was the emphasis placed on physical culture and frequent athletic festivals, he concluded that nothing but good could result if the athletes of all countries of the world were brought together once every four years on the friendly fields of amateur sport, unmindful of national rivalries, jealousies and differences of all kinds and with all considerations of politics, race, religion, wealth and social status eliminated. He summoned an international conference at the Sorbonne, Paris, in 1894, which was attended by the representatives of nine different nations.

The games of the I Olympiad of the modern cycle were held under the royal patronage of the king of Greece in 1896 in a new marble stadium constructed in Athens for the purpose. Subsequent games were held in Paris (1900), St. Louis (1904), London (1908), Stockholm (1912), Antwerp (1920), Paris (1924), Amsterdam (1928), Los Angeles (1932), Berlin (1936), London (1948), Helsinki (1952), Melbourne (1956), Rome (1960) and Tokyo (1964). The XIX Olympiad was awarded to Mexico City for 1968. The games of the VI, XII and XIII Olympiads scheduled, respectively, for Berlin (1916), Tokyo then Helsinki (1940) and London (1944), were not held because of war. In 1906 a set of games was held in Athens, but these were not considered as part of the official series.

A separate cycle of winter games was initiated in 1924 at Chamonix, France; subsequent games were held at St. Moritz, Switz. (1928), Lake Placid, N.Y. (1932), Garmisch-Partenkirchen, Ger. (1936), St. Moritz (1948), Oslo (1952), Cortina d'Ampezzo, Italy (1956), Squaw Valley, Calif. (1960) and Innsbruck, Aus. (1964).

The direction of the Olympic movement and the regulation of the games is vested in the Comité International Olympique (International Olympic committee [I.O.C.]), with headquarters at Mon Repos, Lausanne, Switz. The committee elects its members for life after a thorough investigation. The I.O.C. is a unique organization in that its members do not represent their countries but are delegates from the committee to their countries. No country may have more than three members. Members must not accept from other organizations or from their governments any instructions that may bind them or interfere with the independence of their votes. Baron Pierre de Coubertin headed the committee until he retired in 1925. He was followed by Count Henry de Baillet Latour of Belgium, who served until his death in 1942. The next president was J. Sigfrid Edström of Sweden, who was succeeded in 1952 by Avery Brundage of the United States.

Contestants in the Olympic games must be amateurs. The Olympic definition is as follows:

> An amateur is one who participates and always has participated in sport as an avocation without material gain of any kind. He cannot avail himself of this qualification: (a) if he has not a basic occupation designed to insure his present and future livelihood; (b) if he receives or has received a remuneration for participation in sport; (c) if he does not comply with the rules of the International Federation concerned, and the official interpretations of this rule.

One of the features of the Olympic games introduced successfully for the first time at the Los Angeles games is the Olympic Village. This is special housing provided so that all the competitors from the different countries can live in the same compound.

At the Berlin games in 1936 the sacred Olympic flame, which burns in the stadium throughout the games, was ignited by a torch carried from Olympia, Greece, the site of the ancient games, through the intervening countries by relays of runners. This procedure was repeated at the following games.

The International Olympic committee awards the following various cups and diplomas annually:

The Olympic cup, instituted by Baron de Coubertin in 1906, is awarded to an institution or organization for outstanding service to amateur sport or to the Olympic movement.

The Olympic Diploma of Merit, created at the I.O.C. congress in Brussels in 1905, is awarded for the same reasons to an individual.

The Mohammed Taher trophy, founded by I.O.C. member Mohammed Taher in 1950, is awarded to an athlete who merits special recognition.

The Fearnley cup, founded by former I.O.C. member Sir Thomas Fearnley in 1950, is awarded to an amateur sport club or local association for merit.

The Count Bonacossa trophy, founded by the National Olympic Committee of Italy in honour of I.O.C. member Count Alberto Bonacossa, is awarded annually to a national Olympic committee for outstanding service furthering the Olympic movement.

The I.O.C. has granted its patronage to certain regional games which contribute to the development of amateur sports in the areas where they are organized. These are the Mediterranean games; Asian games; Juegos Deportivos Pan-Americanos; Juegos Deportivos Bolivarianos; and Juegos Deportivos Centroamericanos y del Caribe.

Participation in the Olympic games is organized by the national Olympic committees, of which more than 100 were recognized by the I.O.C. in the 1960s. National Olympic committees must include representatives of all the national governing bodies whose sports are included in the Olympic program. They must be independent and autonomous and must avoid any political, commercial or religious interference. Only national Olympic committees can enter competitors in the games, and they must certify to their amateur standing.

Each Olympic sport is governed by international federations composed of national federations in each participating country. Competitors must belong to these national federations. The international federations write the rules governing their sports, and the events in the Olympic games are under their direction subject only to the Olympic regulations.

Ceremonies.—The opening ceremony of the games, staged in the principal stadium, is impressive. The chief of state of the country where the games are held is received at the entrance of the stadium by the president of the International Olympic committee and the president of the organizing committee, who escort him to a box where he is greeted with the national anthem of his country. The parade of the competitors then takes place. Each national contingent, dressed in its official uniform, preceded by a shield bearing the name of its country and its national flag, enters the stadium in alphabetical order, except that Greece heads the parade and the organizing country appears last. Each contingent after completing its march around the stadium lines up on the centre of the grounds in a column, behind its shield and flag, facing the tribune of honour. The president of the organizing committee delivers a brief speech of welcome and asks the chief of state to proclaim the games open. Immediately a fanfare of trumpets is sounded and the Olympic flag is slowly hoisted; pigeons are released, followed by an artillery salute. At this moment the Olympic flame arrives in the stadium and the sacred fire is lit. A benediction is pronounced and the Olympic hymn is sung. Immediately afterward a contestant from the country where the games are taking place mounts the tribune and pronounces the following oath on behalf of all the assembled athletes:

> In the name of all competitors I swear that we will take part in these Olympic Games, respecting and abiding by the rules which govern them, in the true spirit of sportsmanship, for the glory of sport and for the honour of our teams.

The choir sings the national anthem and the competitors leave the stadium. The ceremony thus comes to an end and the competitions may begin. The closing ceremony, equally impressive, is concluded by the president of the International Olympic committee, who calls the youth of the world to assemble in four years to celebrate the games of the next Olympiad: "May they display cheerfulness and concord so that the Olympic torch may be carried on with ever greater eagerness, courage and honour for the good of humanity throughout the ages." The trumpet sounds, the Olympic fire is extinguished, the Olympic flag is lowered, there is a salute of five guns and the choir sings the final anthem.

Modern Olympiads.—After 1896, interest in each of the Olympic games centred in the sport of track and field, though at times the program ranged from archery through yachting.

In 1896, 13 nations were represented at Athens and this number dwindled to 11 at St. Louis in 1904. There was steady progress after that (*see* Table I). The modern Olympiads fall roughly into three eras: (1) 1896–1912; (2) 1920–32; (3) 1936 on. The first era attracted chiefly athletes from the United States, the British empire and the European continent. The second, after World War I, saw entries from the other continents increase rapidly. The third, which began with the great spectacle at Berlin in 1936, saw the games become a truly global affair.

There also has been continual progress in athletic proficiency, with each Olympiad seeing records broken in almost every sport (*see* Table II). No Olympiad was ever celebrated without the establishment of at least one new world's record in track and field.

The program for the Olympic games usually includes the compulsory events: athletics (track and field), gymnastics, boxing, fencing, shooting, wrestling, rowing, swimming, equestrian, modern pentathlon, cycling, weight lifting and yachting; as well as optional events such as soccer football, water polo, field hockey, basketball, canoeing and, at some Olympics, an exhibition of fine arts. The winter games normally include skiing, skating, ice hockey and bobsled. Women compete in track and field, fencing, gymnastics, canoeing, swimming, yachting and fine arts and, at the winter games, in skiing and skating.

In addition to the amateur code, major Olympic rules include: no minimum or maximum age limit; only nationals may represent a country; there may be no more than three entries from any country in each event (four in the winter games); no contestant may be disqualified on grounds of religion, colour or politics; the games must be completed within 16 days; no point score may be kept in the games, which are contests between individuals and teams and not between nations (groups not connected with the I.O.C., however, often keep an unofficial point score based on 10 points for a first place, 5 for second, 4 for third, 3 for fourth, 2 for fifth and 1 for sixth in each event); the games are entrusted to a city, not a country; the games must be held in the first year of the Olympiad.

TABLE I.—*Participation in the Olympic Games**

(Official, demonstration and optional sports included)

Location	Date	Sports	Events	Participants (women included)	Participating nations
Athens	1896	10	42	285 —	13
Paris	1900	17	60	1,066 (6 women)	20
St. Louis	1904	15	67	496 —	11
London	1908	26	104	2,059 (36 women)	22
Stockholm	1912	19	106	2,541 (57 women)	28
Antwerp	1920	24	154	2,606 (63 women)	29
Paris	1924	24	137	3,092 (136 women)	44
Amsterdam	1928	22	120	3,015 (290 women)	46
Los Angeles	1932	23	124	1,408 (127 women)	37
Berlin	1936	27	142	4,069 (328 women)	49
London	1948	25	138	4,468 (438 women)	59
Helsinki	1952	25	149	5,867 (573 women)	69
Melbourne†	1956	26	148	3,329 (384 women)	67

Hop, step and jump	Tokyo	1964	J Schmidt	Poland	16 85 m.
Shot put	Tokyo	1964	D Long	United States	20 33 m.
Discus throw	Tokyo	1964	A. Oerter	United States	61.00 m.
Javelin throw	Melbourne	1956	E Danielsen	Norway	85 71 m.
Hammer throw	Tokyo	1964	R Klim	U S S R	69 74 m
Decathlon	Rome	1960	R Johnson	United States	8,392 pt †

*These records are unofficial because courses differ. †8,001 pt. by revised table used in 1964.

History of Track and Field.—*Athens, 1896.*—James Connolly of Boston became the first modern Olympic champion when he won the hop, step and jump. His U.S. teammates Thomas Burke, Ellery Clark and Robert Garrett scored two victories each, as did Edwin Flack of Australia. Fittingly enough, a Greek, Spyros Louis, won the marathon race.

Paris, 1900.—Held in conjunction with the Paris exposition, the II Olympiad was another triumph for the United States. Ray Ewry began his unequaled Olympic career with three wins in the standing jumps, Alvin Kraenzlein earned four gold medals and in all track and field events, 17 went to the U.S. A. E. Tysoe, C. Bennett and J. Rimmer scored for Great Britain.

St. Louis, 1904.—This was almost a private affair for the U.S., with few entries from other countries and only one other gold medalist, Étienne Desmarteau of Canada. Ewry again was a triple winner, as were Archie Hahn, James Lightbody and Harry Hillman.

London, 1908.—The most acrimonious of modern Olympiads, this was also the last monopolized by the U.S. and the British empire, who divided 22 of the 26 track and field gold medals. Ewry completed his career with a double victory to bring his gold medal total to eight. Mel Sheppard and Martin Sheridan of the U.S. were also double winners, as were George Larner of Great Britain and E. Lemming of Sweden, the first Scandinavian champion. John Hayes of the U.S. in the marathon and Wyndham Halswelle of Great Britain, in the 400-m. run, scored disputed victories.

Stockholm, 1912.—The name of the greatest athlete in the V Olympiad appears in no record books. He was Jim Thorpe, American Indian, who won the pentathlon and decathlon, but was later disqualified for professionalism. Even without Thorpe's victories, the U.S. was still dominant, with Ralph Craig taking the sprints, schoolboy James "Ted" Meredith setting a world's record in the 800-m. run and Ralph Rose, Patrick McDonald and Matthew McGrath monopolizing the weight events. Finland earned its first gold medals, six all told, with three of them going to Hannes Kolehmainen in the distance runs.

Antwerp, 1920.—After an eight-year hiatus, the Olympics resumed in war-torn Belgium with the largest program to that date. These games saw the debut of Finland's Paavo Nurmi, destined to be second only to Ewry in Olympic track and field victories. Nurmi won the 10,000-m. run and cross-country races; Kolehmainen took the marathon; five other Finnish victories in field events enabled the small Nordic nation to tie the U.S. in track and field events with nine gold medals apiece. Sprinters Charles Paddock and Allen Woodring led the U.S. team, which had no double winner. Twin triumphs were scored by A. G. Hill of Great Britain in the middle distances and Ugo Frigerio of Italy in the walks.

Paris, 1924.—For the first time, a modern Olympiad was completely dominated by one man—Nurmi. In one afternoon, within two hours, Nurmi won and set Olympic records in the 1,500-m. and 5,000-m. runs. Later he added the 10,000-m. cross-country title and also won an unofficial 3,000-m. team race. With Ville Ritola winning the other distance races, Finland surpassed its 1920 record with 10 gold medals. The U.S., however, had 12 this time, with Harold Osborn winning the high jump and decathlon and Clarence Houser taking the shot-put and discus. Harold Abrahams in the 100-m. dash, Eric Liddell in the 400-m. run and Douglas Lowe in the 800-m. run gave Great Britain three individual victories on the track, while the United States had only one such winner, Jackson Scholz in the 200-m. dash.

Amsterdam, 1928.—P. Nurmi bowed out of Olympic history with his sixth gold medal in the 10,000-m. run, but the continuance of Finnish domination of the distance races was assured when Harri Larva won the 1,500-m. run. Ritola took the 5,000-m. run and Toivo Loukola captured the 3,000-m. steeplechase. A 19-year-old Canadian schoolboy, Percy Williams, was the surprise winner in the sprints. Veteran British stars Douglas Lowe and Lord Burghley (David Cecil) took the 800-m. run and 400-m. hurdles, respectively. The U.S. was saved from a shutout on the track when Ray Barbutt won the 400-m. run, but did score heavily in the relays and field events. Asia appeared in the gold medal list for the first time when Mikio Oda of Japan won the hop, step and jump. Women participated for the first time in track and field events.

Los Angeles, 1932.—The great distances involved in travel and a world-wide depression cut the entries in half, but the introduction of the Olympic Village marked the X Olympiad as another advance toward Baron de Coubertin's dream. After its embarrassments of the 1920s, the U.S. made a strong comeback on native soil as records were set in almost every event. Eddie Tolan won and set new marks in both sprints. William Carr set a world's record in the 400-m. run after a duel with another U.S. runner, Ben Eastman. George Saling in the hurdles, William Miller in the pole vault, Edward Gordon in the broad jump, Lee Sexton in the shot-put, John Anderson in the discus and James Bausch in the decathlon were other U.S. champions. British schoolmaster Thomas Hampson set a world's record in the 800-m. run and his teammate Thomas Green won the 50-km. walk. Both relays, 400-m. and 1,600-m., went to the U.S. in world's record times. Lauri Lehtinen and Volmari Iso-Hollo gave Finland two distance victories, but Luigi Beccali of Italy and Janusz Kusocinski of Poland prevented any sweep like those recorded in the 1920s by the Finns, as they won the 1,500-m. and 10,000-m. runs, respectively.

Berlin, 1936.—The role which Nurmi played at Paris in 1924 fell to Jesse Owens, an American Negro, in the XI Olympiad under quite dramatic conditions. Adolf Hitler attempted to turn the Berlin spectacle into a glorification of his Nazi state and the result was that a strong movement developed in the United States against participation in the games. The movement failed of its purpose, however, and Owens was one of five U.S. Negro stars to win gold medals in track and field. Owens won four gold medals, set two Olympic records, tied a third and was part of a 400-m. relay team which set a world's record. Other Negro stars were Archie Williams, who won the 400-m. run; John Woodruff, who took the 800-m. run; Cornelius Johnson, who won the high jump; and Ralph Metcalfe, who ran with Owens on the relay team. Other U.S. champions were Earle Meadows in the pole vault, Kenneth Carpenter in the discus and Glenn Morris with a world's record in the decathlon. Harold Whitlock was Great Britain's only individual winner in the 50-km. walk, but John Lovelock of New Zealand set a world's record as he won the 1,500-m. run and the British team of Frederick Wolff, A. G. K.

TABLE III.—*Olympic Champions, 1896–1912*

Event	1896	1900	1904	1908	1912
TRACK AND FIELD—MEN					
60-m. dash	—	A. Kraenzlein; U.S. (7.0 sec.)	A. Hahn; U.S. (7 sec.)	—	—
100-m. dash	T. Burke; U.S. (12.0 sec.)	F. Jarvis; U.S. (10.8 sec.)	A. Hahn; U.S. (11 sec.)	R. Walker; S.Af. (10.8 sec.)	R. Craig; U.S. (10.8 sec.)
200-m. dash	—	J. Tewksbury; U.S. (22.2 sec.)	A. Hahn; U.S. (21.6 sec.)	R. Kerr, Can. (22.6 sec.)	R. Craig; U.S. (21.7 sec.)
400-m. run	T. Burke; U.S. (54.2 sec.)	M. Long, U.S. (49.4 sec.)	H. Hillman; U.S. (49.2 sec.)	W. Halswelle; Gt Brit. (50 sec., walkover)	C. Reidpath; U.S. (48.2 sec.)
800-m. run	E. Flack; Austr. (2 min. 11 sec.)	A. Tysoe, Gt.Brit. (2 min. 1.4 sec.)	J. Lightbody; U.S. (1 min. 56 sec.)	M. Sheppard; U.S. (1 min. 52.8 sec.)	J. Meredith; U.S. (1 min. 51.9 sec.)
1,500-m. run	E. Flack; Austr. (4 min. 33.2 sec.)	C. Bennett; Gt.Brit. (4 min. 6 sec.)	J. Lightbody; U.S. (4 min. 5.4 sec.)	M. Sheppard, U.S. (4 min. 3.4 sec.)	A. Jackson; Gt.Brit. (3 min. 56.8 sec.)
5,000-m. run	—	—	—	—	H. Kolehmainen; Fin. (14 min. 36.6 sec.)
10,000-m. run	—	—	—	E. Voigt; Gt.Brit. (25 min. 11.2 sec.)*	H. Kolehmainen; Fin. (31 min. 20.8 sec.)
Marathon	S. Louis; Gr. (2 hr. 58 min. 50 sec.)	M. Theato, Fr. (2 hr. 59 min. 45 sec.)	T. Hicks; U.S. (3 hr. 28 min. 53 sec.)	J. Hayes; U.S. (2 hr. 55 min. 18.4 sec.)	K. McArthur; S.Af. (2 hr. 36 min. 54.8 sec.)
110-m. hurdles	T. Curtis; U.S. (17.6 sec.)	A. Kraenzlein; U.S. (15.4 sec.)	F. Schule; U.S. (16 sec.)	F. Smithson; U.S. (15 sec.)	F. Kelly, U.S. (15.1 sec.)
